In the October number of the International Journal of Surgery there is reported by Dr. Norman P. Geis of Brooklyn a case in which sarcoma followed a fracture of the femur. The patient was a boy aged 17 years. He was born in Russia and worked at a rubber factory. Five years previously he had undergone an operation in Russia, but he was unable to give much information about it. All that he could say was that he had had a large swelling on the right side of the lower jaw and that something had been wrong with the bone. At the site of the operation was a scar one and a half inches long. For six months before his accident he had had pain in the right leg extending from a little above the middle of the femur to the instep. The pain was sharp and shooting but intermittent in character. He saw a medical man who prescribed a liniment which seemed to give some relief from the pain. Exercise did not appear to cause any increase of the pain. On Dec. 2nd, 1908, he was pulling a truck when he slipped and fell flat on the abdomen. He immediately felt severe pain in the right thigh and found that he could not use it. He was seen by two medical men who diagnosed dislocation of the hip. Four days later he was treated at the Williamsburg Hospital, where a diagnosis of fracture of the neck of the femur was made, and he was treated with a plaster-of-Paris splint. Nine weeks later the splint was removed, good union was found to have occurred, and he was able to walk about the ward on crutches. Soon after the removal of the splint he noticed a slight swelling at the site of the fracture. This slowly enlarged, and pains like those he had felt formerly appeared, but were more acute, especially at night. The thigh continued to enlarge until when he was first seen by Dr. Geis, it measured 10 inches more than the left immediately below the hip. The thigh was tender on pressure, and the superficial veins were well marked. The swelling was most pronounced anteriorly and externally, and the glands in the right groin were swollen. The general condition of the patient was poor. A skiagram was taken and it showed a sub-periosteal sarcoma. A sufficient number of cases have now been published to make it practically certain that some causal connexion does exist between fracture and the appearance of a sarcoma, but it is difficult to give any very satisfactory explanation of this association. It has been suggested, on the one hand, that the bone has broken because of the previous presence of a sarcoma at the site where the bone has given way, but in many of the cases a very definite interval has occurred between the infliction of the injury and the earliest sign of tumour. Another explanation that has been given is that the mere injury is sufficient to incite the formation of a sarcoma. In the case which we have reported the presence of the pain existing in the limb for six months preceding the

fracture suggests strongly that some abnormal process had then already commenced, and it would be difficult to disprove the suggestion that this abnormal condition was even then sarcomatous. The prognosis of sarcoma of the thigh occurring in these circumstances is very bad, for if amputation at the hip be performed recurrence is almost certain.

CLEAN SHAVING AS A PROPHYLACTIC MEASURE.

A FREQUENT correspondent writes to us that he has noticed that clean-shaven persons appear to enjoy a kind of immunity from the common cold, "at all events," he says, "they seem to be attacked less frequently than those who cultivate the moustache." He suggests that the daily shaving may prove an antiseptic process which regularly removes pathogenic organisms which otherwise lurk and grow in the moustache. It is, of course, conceivable that the moustache affords a nursery for organisms, especially as it must be moist, and occupies a position close to the breathing intake. Further, it is reasonable enough to assume that the daily shave does, as a matter of fact, amount to a regular antiseptic routine. The moustache is obviously difficult to clean thoroughly and it is open to doubt whether mere washing completely sterilises it. Even if that should be the case, the moustache would soon be full of organisms again, as it is constantly exposed to a stream of air which is rarely sterile. According to our correspondent's view, however, there should be a similar immunity enjoyed by women unless we lay stress on the fact that no method in their toilet amounts to the drastic cleansing process of the razor and soap. Moreover, fine downy hair is natural to the lip of women and children. The observation is an interesting one, and its author sends some confirmation of his view in the shape of details of cases in which the subjects, while regular sufferers from common cold when they wore a moustache, seem to have enjoyed a comparative immunity since they have shaved clean.

PHYSIOLOGICAL EFFECTS OF TRAINING ON THE SOLDIER.

A FOURTH report by the War Office Committee on the Soldier's Food, Training, and Clothing, presided over by Sir Alfred Keogh, has recently been issued, containing the results of experiments on marching in the new Mills-Burrowes equipment, as compared with the equipment hitherto in use. In the committee's second report it had been urged that progressive training in marching was most necessary for the recruit; and (as one important point) that orders should! be given to the men to open the jacket and shirt in warm weather, so as to allow free evaporation. In the new pattern, even in full marching order, the belt can be unbuckled, thus avoiding constriction of the body; the water-bottle and haversack have no body-straps, and all the ammunition is carried in the belt and side straps, which are arranged as braces; the chest is therefore as free from constriction as possible. Details are now given of the amount of moisture lost by the body and gained by the clothing, with the old and new patterns of equipment respectively; the advantage is seen to lie with the new pattern, the loss of moisture from the body and its increase in the clothing being on an average less with the new than with the old equipment; on every trial (but one) the air temperature was higher when the new than when the old equipment was tried. The new pattern is slightly heavier than the old by nearly two pounds in drill order, but by only half a pound in full marching order, although 50 more rounds of ammunition are carried. The jacket can be easily opened and the shirt exposed in the new pattern; in the old the belt and straps do not i

allow of this, and the bandolier causes constriction of the chest, which is objectionable. The new equipment can be thrown off, or put on, with one simple movement, so that advantage can be taken of any short halt to give complete relief to the chest; this is impracticable with the old pattern. One drawback is mentioned in the new as well as in the old pattern: it fits close to the back, causing excessive perspiration; this might be obviated. The committee considers that the present clothing of the soldier is suitable for his work, except that there appears to be "a tendency to increase the height and tightness of the collar"; this, of course, is a 'reversion to type" from the low open collar that was adopted as a result of South African experience. The committee also thinks that the full equipment is comfortable and not excessive in weight for a properly trained man. The field-service cap is sufficient protection for the trained man accustomed to exposure to sun, but for most members of the Territorial Army it thinks a light slouch hat would be more suitable. It again urges that "it be an instruction to officers commanding that the order shall be given to men on the march in warm weather to open the jacket and shirt," as it has found that this is not generally the practice; presumably the feeling for 'smartness" still stands in the way of this desirable innovation. This appears to be the committee's final report. It warmly acknowledges the work of the secretary, Captain L. E. L. Parker, R.A.M.C., who conducted experiments in the field and in the laboratory in addition to his secretarial duties. We think acknowledgment is also due to the committee for its valuable work, and especially to the member who did the experimental marches of 14 miles on several occasions in full marching order under a blazing sun.

"NEURASTHENIA QUERULATORIA" AND ITS RELATION TO TRAUMA.

So much attention is directed in these days to the question of industrial compensation, and its application has been so much widened, that it is important for medical practitioners to keep abreast of current doctrine and practice in regard to this most difficult subject. In Germany and Austria in particular, if we are to judge by the output of monographs and articles, and even journals, devoted to the subject, litigation over accidents and the sequelæ of accidents has become annoyingly common. Several recent articles have drawn attention to an all-important, if at first sight somewhat subtle, distinction between the sequelæ of an accident and the sequelæ of the law relating to accidents, between a traumatic neurosis and a "fight-for-compensation" neurosis, to give a literal rendering of the German expres-We may illustrate the point by a case from an interesting communication by Dr. Kurt Mendel in the Neurologisches Centralblatt for November. In the year 1905 an apparently strong young adult received a trifling accident in a locksmith's workshop, and so-called traumatic neurasthenia followed. Although medical opinion ere long certified that he was fit for work again, he never ceased complaining, and the idea of getting further compensation from his employers—in addition to what had been voted him -never was absent from his mind. He left the locksmith's trade and became an employee of a railway company, where he worked for 10 hours a day in a perfectly satisfactory manner. On July 17th, 1907, and again on Oct. 14th, 1907, he had accidents in the engine yard, but in spite of these he wrote to the railway company that he was quite well in every way. The date of this letter was Oct. 23rd, 1907. At this time, be it observed, he was still claiming compensation from his original employers, but when in the summer of 1908 the futility of expecting further

payment from that source was impressed on him his methods changed, and on Oct. 25th, 1908, he wrote a letter to the railway company in which he complained of the usual symptoms, and attributed everything to the two railway accidents. Examination in May of this year showed him to be suffering from tremor of the eyelids, tongue, and hands; the whole body was hypalgesic, the reflexes increased; the mental condition was one of constant querulousness and discontent. When he was offered light work in a garden he refused. saying that he was not yet a lunatic. Dr. Mendel considers this an instructive instance of what might be called neurasthenia querulatoria, in which a characteristic mental and physical neurasthenia supervenes not as the direct result of an accident, but because of litigation pending, with its alternate hopes and disappointments. After the first accident the patient recovered so completely as to be able to work 10 hours a day, and on his own admission he was fit for this work, but the idea of obtaining further compensation remained as the provoking cause of a whole train of mental symptoms which soon expressed themselves in bodily signs. In the same article other cases, equally illustrative, are quoted. Needless to say, treatment of such patients is most unsatisfactory. Some make it a rule not to treat accident cases until litigation is at an end. Dr. Mendel says the only way to make them useful members of society again is to recommend the cessation of all payment, and this plan he has unhesitatingly adopted in a number of cases with most encouraging results.

DEATHS FROM WILD ANIMALS AND SNAKES IN INDIA.

It is a remarkable fact that in spite of the opening out of the country by railways and roads and the clearing of jungle tracts the number of persons killed by wild animals in British India does not show any decrease; in fact, last year the figures rose to 2166, an actual increase of 200 in comparison with the deaths in 1907. In Bengal tigers killed 100 more persons, while in the Central Provinces and Berar the increase was 64. In the Chanda district one tiger alone killed 19 people before it was shot, while panthers and bears accounted for 95-practically double the total of the preceding year. In the United Provinces the mortality was 194 against 159. This increase was due to the ravages of leopards and wolves in the Kumaon and Fyzabad divisions respectively. Leopards seem to abound in Kumaon, and one particularly given to man-eating was still at large at the close of the year, though a reward of Rs. 500 had been offered for its extinction. In Bahraich wolves have become so dangerous that special measures have been taken for their extermination. The number of cattle killed was 87,697 -a decrease of some 1200. In the United Provinces, however, there was a remarkable rise; and in the Almora district this is said to have been due to the wholesale destruction of game, which has resulted in a serious diminution of the natural food-supply of tigers and leopards. It may be noted that in the Kumaon district wild dogs do great mischief, though the Forest Department has entered upon a campaign against them. Evidently there is much work still for the sportsman in various parts of India and there is no necessity to accept any plea for the preservation of the tiger, leopard, or wolf. As to the deaths from snake-bite, the decrease was very satisfactory, the numbers falling from 21,419 to 19,738. This total was the lowest since 1897, and every province shared in the decrease. The official report states that the success of the Lauder Brunton treatment is on the whole encouraging, although the usual uncertainty as to the identification of the snake in the majority of cases still continues. The Commissioner of Agra

reports that the villagers are afraid of the lancets, while the Magistrate of Shajakanpur states that there is a general complaint that the lancets are not sharp enough to make proper incisions where the skin is hard. The results generally reported, however, are such that Government consider they justify further efforts being made to popularise the treatment. It is to be hoped that these will be made, for the application of the lancet and permanganate of potash is simple in the extreme, and the most ignorant person can use the method. It is interesting to note that in Burma the lancets were used with some success in cases of cattle bitten by snakes, and the civil veterinary department might report whether this kind of treatment is really efficacious.

"TRACHEAL PUSHING" IN ANEURYSM OF THE AORTA.

At a meeting of the Société Médicale des Hôpitaux of Paris on Oct. 29th M. E. Hirtz showed a case in which the inverse of the well-known sign of aortic aneurysm—tracheal tugging—was present. The patient was a man in whom the trachea and larynx instead of being dragged down with each heart beat were, on the contrary, pushed upwards in sudden oscillations. Radioscopy revealed an aortic aneurysm but not its exact localisation. M. Hirtz thought that if it was situated in the concavity of the aortic arch it would have caused rhythmical depression of the left bronchus and therefore of the trachea and larynx (tracheal tugging). He believed that the aneurysm was situated at the convexity of the aortic arch. This inversion of the usual tracheal sign of aortic aneurysm does not appear to have been previously described.

THE INNERVATION OF THE SOFT PALATE.

THE nerves supplying the soft palate, and more especially those distributed to the muscles in that structure, have been the subject in the past of considerable controversy. It has, however, been established, especially by the researches of Beevor and Horsley in this country and of Professor L. Rethi in Vienna, that these muscles are supplied through the vagus nerve. Professor Rethi reviewed the whole question in a paper read before the recent International Congress at Budapest and published in the Wiener Medizinische Wochenschrift of Nov. 6th. It was for a long time supposed that paralysis of the soft palate was a symptom of certain forms of lesion of the facial nerve. Certain anatomists maintained that the motor fibres to the levator veli palatini came from the facial, since they succeeded in tracing fibres from the facial trunk through the geniculate ganglion into the great superficial petrosal nerve. Professor Rethi claims that these fibres are not motor in function, since stimulation of the facial trunk does not produce contraction of the muscles of the soft palate. As long ago as 1840 Volkmann, and shortly afterwards Hein. found independently that in freshly killed animals they obtained contraction of the levator veli palatini only on stimulating the vagus roots and not those of the facial. The observations of Beevor and Horsley on monkeys in 1888 established this fact, and Professor Rethi himself has confirmed it in a large series of observations on different animals. He has also found that the motor fibres for the levator leave the medulla in the median roots of the vagus, and that they originate in a common nucleus with the other fibres of these bundles. He has traced them down the lateral wall of the pharynx to the velum itself. These observations have been confirmed by Kreidl, and also by Chanveau in the horse. In man the same facts have been established. There have been cases in which the origin of the facial nerve has been destroyed without any paralysis of the soft palate, especially

in the interesting case described by Rosenthal, in which a new growth of the base of the skull extended into the Fallopian aqueduct and destroyed the great superficial petrosal nerve. On the other hand, numerous cases are on record where lesions of the vago-accessory fibres have been assoclated with paralysis of the soft palate. Professor Rethi has also investigated the secretory nerves of the soft palate. He has found in different animals, especially in cats, that local electrical stimulation produced secretion in the neighbourhood of the electrodes. Stimulation of the facial trunk at its entry into the internal auditory meatus produced secretion strictly limited to the same side of the soft palate. Secretion was also produced by stimulation of the cervical sympathetic. It was found that the secretion from stimulation of the facial nerve was more concentrated than that resulting from stimulation of the sympathetic, these results being the reverse of those obtained with the salivary glands. Professor Rethi was able to trace the secretory nerves from the facial trunk into the great superficial petrosal nerve and on into the Vidian, into which the sympathetic fibres also pass from the great deep petrosal nerve. The fibres thence pass together to the spheno-palatine ganglion and are distributed to the soft palate by the palatine nerves. He therefore concludes that the facial fibres going to the soft palate, which have by some been regarded as motor in function, are in reality secretory. His observations establish in an interesting and convincing manner the functions of the different nerves distributed to the soft palate, and make clear the innervation of the glands found in that structure.

PELLAGRA IN THE UNITED STATES.

This year's returns of the world's production of maize (Zea mays) show that more than 70 per cent. comes from the United States, which country produces at least 17 times more of this cereal than Austro-Hungary or Argentina, which are the nearest competitors. It has sometimes seemed strange to students of pellagra problems that the United States should be believed to be so free from this scourge, but it now appears that in many of the Southern States pellagra has been present for some years, though not correctly diagnosed till lately. On the American continent pellagra has been reported from Brazil, Uruguay, the Argentine Republic, and Mexico, but it was not until 1863 that sporadic cases were recognised in the New York and Massachusetts hospitals. But little more was heard of pellagra till 1902, when Dr. S. Sherwell and Dr. H. F. Harris each reported a case. In 1907 additional cases were brought to light, physicians visited Italy to confirm their impressions, and this year the public health reports, issued by the Treasury Department of the United States, give a table showing that about 1000 known cases of pellagra are scattered in 13 of the Southern States. More than half of these cases have been recorded from lunatic asylums or similar institutions. Dr. J. W. Babcock, superintendent of the State Hospital for the Insane, Columbia, South Carolina, was one of the earliest to recognise the existence of pellagra, and was one of those who visited Italy and England to confer with those acquainted with the disease and its complications. It is chiefly due to his energy that a "National Conference on Pellagra" took place in his hospital on Nov. 3rd and 4th. The conference was attended by 600 physicians from different parts of the United States, including official representatives from the Army, Navy, and Public Health and Marine Hospital Service. Many clinical cases were presented for study, and, in addition to some 40 papers read by American physicians, communications had been obtained from Dr. A. Marie (Paris), Dr. F. M. Sandwith (London), and Dr. J. Warnock (Cairo). Four resolutions were

unanimously adopted by the conference, besides those which conveyed formal compliments.

3. That the purposes for which this conference was called can best be furthered by its formal organisation into a permanent association of national scope, and that the committee on permanent organisation be instructed to report at this session.

4. That, this conference recognizes the widespread existence of

instructed to report at this session.

4. That this conference recognises the widespread existence of pellagra in the United States, and urges on the national Government the necessity of bringing its powerful resources to bear on the vital question of its cause, prevention, and control.

5. But while sound corn is in no way connected with pellagra, evidence of the relation between the use of spoiled corn and the prevalence of pellagra seems so apparent that we advise continued and systematic study of the subject, and in the meantime we commend to corn growers the great importance of fully maturing corn on the state before cutting same.

6. That the work of this conference be brought to the attention of the

That the work of this conference be brought to the attention of the various state and territorial boards of health, and that they severally be urged to specially investigate the disease, particularly as regards its prevalence, and that they also see that the proper inspection of corn products and that they also see that the proper inspection of corn

products sold in the various states be had.

The conference, on completing its labours, formed a permanent society to be known as "The National Association for the Study of Pellagra." Dr. Babcock was elected as first President, and the next meeting is to be held in June, 1910, in Peoria, Illinois, whence many cases of pellagra have been reported.

PROFESSOR ADAM POLITZER'S JUBILEE.

On Dec. 9th Professor Politzer will celebrate the fiftieth anniversary of the attainment of his doctor's degree, and occasion will be taken of this jubilee to do honour to the great otologist. A festival has been arranged by the Austrian otological societies, at which a number of addresses will be presented by kindred societies in other countries. The University of Vienna will renew the professor's diploma and cause it to be presented by some of its leading members. It will be remembered that when Professor Politzer retired from the chair of otology at Vienna two years ago a similar festival was set on foot; this had to be abandoned at his express wish on account of a family bereavement. At that time a gold medal bearing his portrait was struck and presented by otologists from all parts of the world to the great teacher from whom so many had received their inspiration. The present occasion will be welcomed as an opportunity of giving expression to their homage in a more personal manner. For 46 years lecturer in the University of Vienna, Professor Politzer has exerted an immense influence upon the course taken by modern otology, an influence which derives its strength from its solid basis of anatomical and pathological research. His numerous contributions to the literature of the subject are well known to otologists, but the monumental "Text-book of Diseases of the Ear" has been recognised as a classic by the whole profession. Within the last two years he has published the "History of Otology," a work which represents an immense amount of literary research of the widest range. In spite of advancing years Professor Politzer retains the vigour of middle age, and there is every reason to hope that he will remain many years the distinguished feature of international gatherings of otologists and the active leader of their branch of medicine. His British colleagues, many of whom have come under his personal influence at Vienna, welcome this opportunity of expressing their regard to a great teacher, and this expression will take official form in an address presented by the Otological Section of the Royal Society of Medicine, of which he is an honorary member.

At the anniversary meeting of the Royal Society on Nov. 30th Professor J. Rose Bradford was re-elected secretary in conjunction with Sir Joseph Larmor. Amongst those elected to the council were Dr. W. H. Gaskell and Dr. C. J. Martin. Sir Archibald Geikie was re-elected president. The annual dinner was held on the same evening at the Hôtel Metropole.

WE much regret to announce the death of Mr. Marcus Gunn, senior surgeon to the Royal Ophthalmic Hospital, Moorfields, and ophthalmic surgeon to the National Hospital for the Paralysed and Epileptic, Queen-square, W.C., which occurred at Hindhead on Monday last, Nov. 29th.

THE Bradshaw Lecture will be delivered at the Royal College of Surgeons of England by Mr. F. Richardson Cross, on Friday, Dec. 10th, at 5 P.M. The subject of the lecture will be: "The Brain Structures concerned in Vision, and the Visual Field."

THE King has been pleased to appoint Mr. A. J. Ram, K.C., a member of the Royal Commission on Vivisection, to be chairman of the Commission in the place of the late Viscount Selby.

THE Governor of Mauritius reported 38 cases of plague with 14 deaths during the week ending Nov. 25th. The Governor of Hong-Kong reported 1 fatal case of plague last week.

THE death is announced of Duke Karl Theodor of Bavaria, who has for many years practised as an oculist amongst the poor of his country.

THE MEDICAL PROFESSION AND THE POOR-LAW MEDICAL SERVICE.

BY MAJOR GREENWOOD, M.D., D.P.H., LL.D., HONORARY SECRETARY OF THE POOR-LAW MEDICAL OFFICERS' ASSOCIATION.

OF all the changes that might arise from the carrying out of the recommendations of the late Royal Commission on the Poor-laws there is none more important or that has greater claim to the careful consideration of the medical profession of the country than the future development of the Poor-law Medical Service. While admitting that the medical treatment of the sick State poor cannot be regarded as affecting that service only, none the less it is the interests of its members that are more directly implicated, and they may fairly claim the sympathy of their professional brethren and assistance in maintaining their rights and in procuring the reforms which they consider necessary for the efficient carrying out of their public duties. When the proposals in respect of medical relief of the Commissioners were first published they came as a shock to most Poor-law medical officers. Although the medical machinery of the Poor-law had least come under popular condemnation, it was that service that was singled out for the most radical treatment. For many years Poor-law medical officers had been agitating for important reforms, the necessity of which was amply recognised by the Commissioners themselves; but instead of obtaining what they asked for, it was decided to revolutionise the whole service.

It is certain that the great majority of Poor-law medical officers dissent from the medical recommendations of all the Commissioners, and they do so in company with the only representative of the profession on that Commission, and the one that, above all the others, has the greatest knowledge of the practical working of the present system and of the chief needs of the sick State poor. It is to be hoped that the Poor-law Medical Service will receive the support of the roor-law Medical Service will receive the support of the medical profession generally, as it is very desirable that the public medical services of the country should not lack that the public medical services of the country should not lack that

assistance which they have every right to expect from their brethren. The great majority of Poor-law medical officers rely more on private practice than on their Poor-law appointments, and it is evident that their chief interests are identical with those of the ordinary practitioner. They may be relied on, therefore, to seek to minimise as far as possible the imminent danger to private practice generally among the poor that is threatened by any large scheme of Poor-law medical reform, carried out on the lines of either the Majority or Minority Report.

The Poor-law Medical Service consists of some 7000 medical practitioners, the great majority of whom are district medical officers. It is thus a very considerable service and has been in existence since 1834. It may be fairly described as one of the chief creations of what Sir William Harcourt styled "the great Poor-law settlement" of that year. At the present time, if open to some of the criticism of the Commissioners, it is practically attending to the wants and necessities of the sick State poor in every corner of England and Wales. Most of these district medical officers are part-time officers and in most cases dependent on their private practice, and this fact must not be lost sight of, for it is clear that an improvement in their official position would be dearly bought at the expense of their private practice. For that reason it is necessary for them in considering the various recommendations of the Commissioners to look beyond the mere betterment of their position as public officers. The Majority Report is favourable to them in one particular. It recognises the necessity of a Destitution Authority, whether known by that name or not. Without such an authority the relations between practitioners and their poorer patients throughout the country would be profoundly altered, and even if a considerable amount of the cost for attendance on improper applicants for State aid were recovered by means of the "Consistent Code" of the Minority it would not go into the pockets of the men, whose patients had been But there is more than this: without tempted away. a Destitution Authority there can be no Poor-law Medical Service at all. Officers of the present service might be tacked on to the Sanitary Medical Service; but not possessing in many cases the D.P.H. diploma, they could hardly aspire to its highest honours, and as a Poor-law medical service their occupation would be gone. regard to the medical scheme of the Majority, this need only be mentioned to be condemned; to no Poor-law medical officer would it be acceptable. It would tend to abolish his office and injure his private practice. The criticism of the Minority Commissioners is sound here, and the opinion of the only medical member of that Commission as to its merits quite conclusive. Neither Poor-law medical officers nor other practitioners desire to see an increase of contract practice of this kind, and the former do not believe that bond fide provident dispensaries can be grafted on to Poor-law institutions. The United County Medical Service of the Minority can only be attractive to those Poor-law medical officers who desire to be amalgamated with another service and to be wholetime officers, who consider their interest will be better served by retiring from private practice and becoming State officials. Speaking generally, it is certain that the majority of the Poor-law medical officers of the country do not desire anything of the kind. They are well aware of many of the defects in the service that have been brought to light by the Reports of the Commission, and would welcome their removal. But to remedy them they see no reason for the drastic changes that have been proposed both by the Majority and Minority. They regard the present medical service as a necessary and efficient department of the State, needing reform in details but not abolition.

The more important recommendations of the Majority, touching a change of authorities, might readily be adapted to the present medical service, and most of the existing officers would suffer no injury, but might hope for an improvement in their status and more adequate payment. The proposed enlargement of areas might require some redistribution

of the present districts, but in most cases the district medical officer would continue to work on the same lines as heretofore. The Sanitary and Poor-law Medical Services would be kept distinct, the one preventive and the other curative, except that there might be transferred to the former the institutional treatment of all notifiable infectious disease. But although separate, there might be much more coordination between these services than hitherto. Dr. A. H. Downes says in his memorandum to the Majority Report that provision for this already exists, and could be developed without difficulty. All this is in fair accord with the Majority Report, if the medical scheme be omitted, but so far as the needs of Poor-law medical officers are concerned it is immaterial what Destitution Authority is decided upon, provided it is not identical with the sanitary committee of the county authority.

The chief reforms sought by the Poor-law Medical Service are: (1) More adequate payment for their work; (2) better security of tenure; (3) better provision for the nursing of their outdoor State patients; (4) security for payment of midwifery and other special fees, as for operations and for the administration of anæsthetics; and (5) the provision of all medicines and medical and surgical requisites by the State. With reference to the proposal to make the medical practitioner into the relieving officer quad applications for medical relief, while Poorlaw medical officers would not object to a modification of the present system under special circumstances, where application to the relieving officer was impracticable, they could never approve it as a general practice. In their opinion they could not carry out the important public duties of the relieving officer efficiently, and the attempt would constantly cause friction between them and their professional brethren not holding Poor-law appointments. The latter, as it is, sometimes object to the order given to their patients whom they think able to pay, and this friction would be greatly aggravated if instead of the relieving officer it was a rival practitioner who officially interfered.

Poor-law medical officers object to a radical distinction between medical and other relief. Medical relief is not more necessary than other kinds of relief, and if it is good for the State that the indigent poor should receive medical attendance it is equally necessary that they should be properly fed and clothed. It is pure sentimentalism to draw a distinction between the application for medical assistance at the cost of the State and any other form of necessary relief. Both are equally pauperising, and their only justification is the real need of the applicant. That this need may be real and not counterfeit, it is most important that all applicants for State relief should be under the supervision of a special officer and that there should be no interference on the part of the medical man with his special duties.

The absolute necessity of keeping the Poor-law Medical Service as a separate entity was the point which I insisted pon in some remarks which by their courteous invitation I made recently to the Society of Medical Officers of Health. I may be excused for repeating my words The substance of the reforms that have hitherto been proposed must—I said—profoundly affect the position now held by Poor-law medical officers, and may not unlikely result, if carried out, in some modification of the offices held by the members of your service. At any rate our two services are the only public medical services that are likely to go into the melting pot, and for that reason it seems to us there is the utmost need that we should endeavour to come to an agreement, and take counsel together, as to what steps should be taken to defend our common interests. In saying this it must not be supposed that I forget that as public officers we only exist for the good of the nation, and that the national interest alone is, after all, the chief desideratum. But neither service is unmindful of this fact, and both consider the true interests of the respective services to be that they should be made as efficient as possible to do that public work which the exigencies of the national welfare require of us respectively. We of the Poor-law Medical Service have made up our minds that our extinction, threatened by the Majority and Minority Reports alike, is not good for the public welfare, and that a distinct Poor-law Medical Service, both indoor and outdoor. ought to be continued; therefore, we could not join in any

attempt to support the Provident Dispensary Scheme of the Majority Commissioners. We emphatically deny that it would be a good thing either for the public or the poor, and we believe it would be ruinous in its effects on that portion of our common profession practising in poor districts. We further condemn the principle that every practitioner who wished should be a Poor-law medical officer, and we consider that there is scarcely any public medical service in the country that has better claims to be recognised as a distinct service than has the Poor-law. Granted the maintenance of our service, we are quite ready to welcome any suggestions which the Sanitary Service or the Society of Medical Officers of Health may formulate and to consult with them on common grounds to bring about all possible cooperation between the Sanitary and Poor-law Service of the country.

I think it not unlikely that from many points of view the proposals of the Minority Report may seem attractive to the Sanitary Medical Service. If the medical treatment of the sick State poor is to resolve itself into a mere question of sanitation, it is probable that the service whose special appanage sanitation is would, as Mrs. Webb phrases it, get all the "plums." But, on the other hand, the Minority Commissioners also propose to enrol the present Poor-law Medical Service in the ranks of the Sanitary Service, and Mrs. Webb has also plainly said that in the future the newcomers may expect to share in these "plums." There is, therefore, every prospect that posts now only open to professed sanitarians will, if the Minority scheme be carried out, be thrown open to a much larger circle. This, in my opinion, is not to the advantage of the present Sanitary Service. It must not be forgotten that even if a certain number of the present Poor-law medical officers are pensioned off, there will remain in round numbers about 3000 to find places in the new Sanitary Service, and all these under the scheme are to be allowed to compete for the plums in that service. To allow this to take place some modification would have to be made in the rights possessed by those who hold diplomas in public health. It has been suggested that present Poor-law medical officers who become partly health officers should not be debarred from the higher sanitary offices on account of the non-possession of that diploma. Whether such an arrangement would meet with the approbation of the medical officers of health of the country I do not know. It is, at least, questionable whether for the public good it is wise to mix up in one service clinicians and sanitarians; and especially, whether the science of public health would gain by such an admixture. On the other hand, as sanitary knowledge is necessary for the successful carrying on of all medical practice, if the Poor-law Medical Service of the future were kept distinct, as now, it might easily cooperate far more with the public sanitary service than it has hitherto done; and the true principle, in my opinion, to form the basis for future Poor-law reform is to try to get this cooperation while retaining a proper distinction between the clinician and the sanitarian. It seems to me that under any workable system the country must be divided into districts, and the actual treatment of the sick State poor must be in the hands of clinicians—that is, of district medical officers. An exception might be made in the case of infec-The treatment, and every other detail contions disease. nected with it, has naturally drifted into the hands of the Sanitary Service, as is only right and proper, and good reasons can be given why all forms of infectious disease may be safely treated at the public expense. But it is otherwise in the case of ordinary disease. If at times it may be difficult to draw the line, in most cases a broad line of demarcation can be drawn between the two kinds of disease.

I think, then, there should be a distinct service to deal with ordinary disease occurring among the sick State poor, and that the present Poor-law Medical Service, indoor and outdoor, or some modification of it, is the best fitted to do this public work.

THE PLUMBERS' COMPANY.—The Lord Mayor, in his capacity of Master of the Plumbers' Company, has signed the first batch of certificates awarded since his accession to office to plumbers (master and operative) of the suburbs of London upon their passing the examinations prescribed by the managing committee for the National Registration of Plumbers, and entitling the holders to describe themselves as registered plumbers, subject to their maintaining a satisfactory standard of work in the public interest.

SOME CONSIDERATIONS OF MEDICAL EDUCATION.

 VL^1

The Position of the London Medical Student.

In the foregoing chapters many of the difficulties have been expressed that exist in arranging a curriculum for the medical student, which will at the same time cover the many provinces of learning with which the medical student is supposed to be familiar, and also be a possible course of education for him to go through within a reasonable time. Various solutions of various problems have been discussed, problems now under the consideration of the General Medical Council, and in many of these it has been necessary to take into account the peculiar position of the London student.

The position of the London student need not, however, be described at any great length or with any abundance of detail here, because, firstly, it is such an old topic in our columns that we can with fairness take it for granted that all our regular readers are familiar with the points at issue; secondly, our medical and lay contemporaries have recently devoted great attention to the matter, and have published much valuable information for the assistance of those who want to make up their minds in a difficult situation; and thirdly, there is at the present moment a Royal Commission sitting to inquire into the working of the University since its reconstitution, and presumably the evidence given before that Commission will place all interested in full possession of the facts. We must, however, briefly retell the old story, begging our readers at the same time to remember the vital importance of the issues at stake.

The salient faults in the present system of medical education, which though called faults are nobody's particular fault, arise from a commingling two sets of circumstances, the ever increasing scope of medicine and the large and also increasing number of educational authorities able to bestow qualifications for practice upon their students, but not regarding the curriculum with the same eye. The two things can be talked of separately, but it is their simultaneous occurrence and vexatious interaction which cause the difficulty in London. The medical degree of the University of London has long enjoyed the highest prestige. If this degree is to be admittedly the hall-mark of advanced scientific medical education the Senate of the University must take pains to see that the examinations are of the sort that prove students to be to some extent familiar with the latest pathological developments. But if this is done at the expense of the more rudimentary parts of the curriculum the examinations become a string of academic acrostics, the students fly to coaches for assistance, and the General Medical Council may find the examinations, as it has If it is already done on one occasion, unpractical. attempted to meet the case by being thorough from the beginning, by insisting that all the students, after a satisfactory preliminary examination, and a searching inquiry into their preliminary and special scientific equipment, shall show such acquaintance with clinical work that they are ready to take the field on qualification as adequate practitioners, how is time to be found to instruct and examine these young gentlemen in electro-therapeutics, in blood pathology, in the psychological side of neurology, and so on? It is clear that all this cannot be learned in a curriculum of five years' duration, while it is probable that the social class from which the medical student is recruited can ill bear the cost of more than five years' studentship. These things being so, the simple way out of the dilemma would be, it seems, to insist that the curriculum should be devised with the idea of moulding the student into a practitioner, and that the more scientific developments should follow in accordance with the desire of the student to specialise in one direction more than

another-to do laboratory work, or special consulting work, or operating work. But immediately the difficulty of the numerous centres which can confer upon the student the right of qualification makes itself felt. The universities. or certain of them, desire to maintain their degrees at a higher level than is thus signified, and it is right that they should do so, not only because every upward aim ought to be encouraged, but because they reward their students at the end of the course with a medical degree, conveying the legal right to the title of "Doctor"—not a small point as we all know. But what if Universities do not keep their examinations at any higher level than those of the corporations which reward their students only with diplomas, not conveying the legal right to the title of "Doctor"? This is a grave hardship to the students of the Royal Colleges, who have done work for their College tests which would have earned them at a university a medical degree, and the student in London, where the medical degree is particularly hard to obtain, is the typical sufferer.2 What the public require are men to treat them and to heal them in the conditions and emergencies of sickness. There is something very wrong when a large number of men educated presumably towards this end cannot obtain the legal right to the title which in the public eye stands, or may stand, for the proper medical qualification. In London to obtain that title the student must do work that is not of the kind to enhance his utility as a practitioner; and further, this work may have been done in time which has been taken from ward work to such an extent that he may be unfitted for his clinical duties.

In the present state of affairs the universities and the corporations cannot be expected to view with similar approval the institution of a State degree in medicine, wherefore Parliament cannot be invited with any real vigour to sanction the introduction of measures with such an object, but some of the undoubted benefits that would be secured by a simplification of the educational curriculum could be created if our universities and the various corporations would work in unison under the existing educational scheme. In taking the London case for an example it must be remembered that the present plight of the London student may become the plight of the Dublin, Edinburgh, and Glasgow student at any moment, and already there are signs that in Dublin and Glasgow the rivalry between the universities and the corpora tions may have very unfortunate results for the licensing faculties.

Any understanding that might be come to between the University of London and the London medical schools is complicated by the number of medical centres in the metropolis. There are in London 12 medical schools—13, counting both the school for women and the school attached to St. George's Hospital, now to some extent merged in the King's College School of Medicine-and all these offer to teach the medical student everything that he requires from Each school the start to the finish of the curriculum. possesses, in addition to lecturers upon, and demonstrators of, anatomy and physiology, teachers of all the ancillary subjects, and each maintains the necessary class-rooms and laboratories for such an undertaking. 50 years ago, the scope of the medical student's education being what it was, a medical school attached to a metropolitan hospital could easily provide the necessary facilities for a student; and 25 or 30 years ago the separate schools were all working fairly satisfactorily, though the present conditions of unrest were clearly visible. But since 1880 the cost of medical education to those who provide it has been increased out of all proportion to any increase in fees demanded students, and this has had a disastrons from the effect upon the subdivision of effort prevalent in London. The developments of biology, physiology, bacteriology, chemistry, and electrical science have all conspired to involve in heavy expense any medical school seeking to be completely equipped. All the London medical schools have answered bravely to the demands made upon them, and it appears to be their intention to continue in the same gallant course; but they cannot go on if the supply of students fails them, for the income from fees is lost; while as long as the idea is abroad that the London medical student does not obtain his M.D. degree upon reasonable terms the shortage

¹ Nos. I., II., III., IV., and V. were published in The Lanuer of Oct. 23rd (p. 1232), 30th (p. 1301), Nov. 13th (p. 1459), 20th (p. 1531), and 27th, 1909 (p. 1616), respectively.

² See "Some Problems of Medical Education in London," an address delivered by Sir William Allchin on the opening of the medical session of Oct. 1st, 1907.

of students will occur. It is this shortage of students that keeps the matter of the consolidation of the London medical schools before the public mind. The number of medical students in Scotland appears to remain about the same as it has been for the last decade; quite recently the number of medical students in Ireland has begun to show an upward tendency; England is the only division of the United Kingdom where the number of students has perceptibly gone down, and it is in London that the decrease has occurred; and one reason certainly is that the University of London and the Royal Colleges have been unable to come to any joint arrangement by which a medical degree could be obtained upon reasonable terms by the diplomates of the colleges. This is a matter of moment to the English Royal Colleges, because it is from the London students that they draw much lucrative support, although they are as a matter of fact Imperial corporations.

The average London student must become an L.R.C.P. London, M.R.C.S. England, supposing that he is not satisfied with the Licence of the London Society of Apothecaries; the other support received by the Colleges is fortuitous although it is so large. Until the new great provincial universities were added to the Universities of Oxford, Cambridge, Durham, and Victoria, the mass of the English provincial students were compelled to take the London diplomas; now they need do so only if they like, for these new degree-granting institutions offer them the title of M.D., perhaps with no inconvenient and expensive change of residence. As yet the competition of the provincial universities may not be very severely felt by the Colleges; the double diploma of the English Colleges is still the termination to the recognised English medical curriculum. But this state of affairs may not last; at any moment the mass of average students may decide that they must obtain medical degrees upon reasonable terms somewhere, and the number of provincial universities may increase.

The Colleges are fully aware of the situation, and it is probable that the governing bodies recognise the fact that the only certain way to attract medical students to London again is to give them the same chance of obtaining a medical degree that they would enjoy if they lived in Liverpool or Newcastle. But this can only be done if the University of London will join in some scheme for the purpose. Many think that it would be facilitated if all the different London medical schools agreed to consolidate their purely scientific teaching, but this is a matter upon which there are strong differences of opinion. To support 12 centres in London for the instruction of students in chemistry, anatomy, and physiology, when the work could be better done from, say, three centres by properly paid teachers, must always seem extravagant, while it militates against a fusion of interests between all the London medical students, which would be a very valuable asset to the University of London.

It must not be supposed that the Royal Colleges have been apathetic under adverse circumstances. On the contrary, they have done much. When the Colleges first became aware, mainly no doubt through teachers at the London medical schools, who were also members of the governing bodies of the Colleges, that unless the London students could obtain an M.D. degree more easily they would seek graduation elsewhere, their first idea was to obtain powers to grant such a degree themselves. The opposition, however, to giving to corporations the degree-granting powers similar to those possessed by universities proved too powerful for the success of any such scheme. At best it was a retrograde scheme, under which it was proposed to give to the London students, who already possessed a university which they did not use, the hall mark of a university without any other of the features of a university career. For the time the move would certainly have been popular, but no academic position would have accrued to the holders of such a "degree," and the Members and Licentiates of the Colleges would soon have found this out. The next course taken was to try to obtain from the University of London, the old University of London. some concession whereby the chances of the London students obtaining a medical degree should be increased. That these chances were very meagre was sufficiently proved by the fact that in the first 40 years of the existence of the

University, though upwards of 2000 medical became qualified yearly from medical schools where they might have graduated as M.B. Lond, if they had chosen, only some 800 men, or an annual average of 20 men, proceeded to the degree. The then unnecessarily elaborate demands of the matriculation examination of the University were held to be the chief reason for this dearth of medical graduates, though the "preliminary scientific" examination . also came in for criticism as being based upon a syllabus that was unpractical in a medical curriculum. As might have been expected, the existing medical graduates of the University held strictly opposite views upon the propriety of altering the character of the tests. A large proportion of them having worked hard and made many sacrifices to obtain an honour degree were averse from any change being introduced into the curriculum so that others should obtain the degree upon easier terms. A smaller section did not consider that the University as a whole benefited by fencing its medical degrees round in such a stringent manner, believing that many of the demands made upon the time and memory of the candidates for the degrees were not in the least likely, even if they were met successfully, to help in the manufacture of a particularly sound practitioner. The strength of these two opposite views was enhanced by the unfortunate fact that each party could call the other self-interested. The holders of the medical degree who wished to have its face value maintained in any manner, however artificial, were certainly playing their own game; the medical graduates of the University, who were also important personages in the Colleges, might be regarded as no less certainly watching the case in behalf of their corporations or their schools. University did not see its way to meet the Colleges, and the friends of the London medical students were constrained to fall back upon a third course. The existing University being unable to help them, and the privilege of giving degrees being denied to the corporations, the third alternative was a new university, of which the Colleges should in some way or other form the medical faculty. The scheme came near to realisation, and the "University of West-minster" received the support of the Privy Council, the ultimate authority on medical education, as being the body under which the General Medical Council exists. It, however, failed, there being no real impetus behind the movement at the critical moment.

Then came the reconstitution of the University of London, the most powerful factor in which was, perhaps, the feeling of the medical section that the education and examination of their students required revision and arrangement. In the new scheme the Senate of the University was given powers to make arrangements to conduct examinations conjointly with the Colleges, and undoubtedly the general feeling in the London schools was that some system of "pass" and "honour" degrees in medicine would be instituted, so that on the one hand the prestige attaching to a very stringent curriculum should be maintained, while a medical degree, as high in standard as far as purely professional attainments were concerned as any other degree in the country, would be made available for the generality of the London students. The Faculty of Medicine of the new University, including in its body many recognised teachers of the London medical schools, received a report from a committee which it had appointed to consider the reform of London medical education, advocating as an initial step the concentration of study in the preliminary scientific subjects as a way of bringing all the London students into touch with both the Colleges and the University. An appeal was made to the public by Lord Rosebery, the Chancellor of the University, and all the chief officers of the University, begging for the support of a Central Institute of Medical Sciences, and received in the first instance hearty support. The chairman or the treasurer of every London hospital concerned ranged himself on the side of the movement, which seemed to have secured a splendid start. Later, a small but very influential and business-like committee, appointed by King Edward's Hospital Fund for London, to make an inquiry into the allocation of the funds of these charities, appended to their report, which was necessarily based upon information in regard to the expenses of, and receipts from, the schools attached to the hospitals, a strong recommendation of the principle of the consolidation of medical study. But the movement so long expected, so definitely fore-shadowed in the new constitution of the University, so-

³ In what follows the writer has availed himself freely of the writings of Sir William Allchin, whose well-known volume on the University of London is a mine of information on the whole subject.

happily inaugurated and so powerfully supported, came The idea of one central institute was for to nothing. various reasons replaced by a scheme for three centres which did not appeal to several of the London medical schools. The two largest schools-those of St. Bartholomew's Hospital and the London Hospital-were soon seen in definite opposition to it; gradually several other schools, possessing by no means the same sound reasons for desiring independence, were none the less found to be averse from the form of consolidation offered; and the Senate of the University resolved to return to the donors the £70,000 which had been collected for the Central Institute of Medical Sciences, and The Senate not to pursue any such scheme to realisation. could plead in defence of their action that £70,000 was not a large enough sum wherewith to build and endow the new Central Institute, and that the metropolitan medical schools no longer wished to see it founded, so that their position if accused of vacillation or retrogression is a strong one. But in the meantime the London medical student remains as far off as ever from an adjustment of his difficulties, and the shortage of medical students desiring to take the diplomas of the Colleges becomes more pronounced.

The English Colleges have, however, now taken, as our readers know, a most important step. In the autumn of 1908 delegates were appointed by the Colleges to consider a draft scheme which, if approved by the Colleges, might be submitted to the University of London with the object of establishing a system of joint examinations between the Colleges and the University, the action of the Colleges having its origin in the desire of the governing bodies to meet the difficulties which have just been described in detail as lying before the London students in their endeavour to graduate in medicine at their University. The responsibility of reporting on the situation was delegated to Sir Richard Douglas Powell, Sir Henry Morris, Sir William Allchin, Mr. Butlin, Dr. H. A. Caley, Sir W. Watson Cheyne, the late Mr. H. H. Clutton, Mr. R. J. Godlee, Mr. A. Pearce Gould, Dr. Edward Liveing, and Dr. Norman Moore. They made their report to their Colleges in December, 1908, which was duly approved and adopted by both corporations. The report, having pointed out that one statute of the University of London definitely permitted the Senate of the University to make arrangements with the Royal Colleges to conduct joint examinations in any part of the curriculum, went on to show that roughly one-half of the diplomates of the two Colleges are also graduates in medicine, proving that there is a general desire among those who intend to take university degrees, or who already possess them, to hold also the diplomas of the Royal Colleges.

The report then points out how desirable it is that in London the system of teaching and examination should be coördinated in such a manner as to reduce the number of examinations. In London the same representatives of medicine, surgery, midwifery, anatomy, physiology, and other subjects teach and examine at the University and the Royal Colleges, while the organisation of medical education in London is largely controlled by the same individuals. But there are separate boards of examiners appointed by the University and by the Royal Colleges in all branches of study, as well as separate examinations—an obviously expensive position. In considering the scheme for reorganisation the delegates take as a basis the following principles:—

ciples:—

In considering such a scheme the delegates have taken as a basis of their deliberations the following principles: (a) That the University should retain all its existing rights as to the granting of degrees, but should consent to exercise them as regards Pass Degrees conjointly with the Royal Colleges so far as those students are concerned who shall have spent not less than four years in study at London Medical Schools and Hospitals and who shall have complied with such conditions as the University and the Royal Colleges may determine. It is assumed that the University will continue to grant, independently of the Royal Colleges, Degrees in Medicine and Surgery which might be called Honours Degrees. The views of those who maintain that the present Degrees of the University of London are of an Honours' standard would thus be met. (b) That the Royal Colleges should retain all their existing rights, to grant diplomas to those who hour in ont eligible under the foregoing conditions; or (2) do not desire to come under such conditions. It is thus assumed that the Royal Colleges will continue to admit to examination for their diplomas candidates from other universities, home, foreign, and colonial, as well as London medical students who are not students of the London University. (c) That the Royal Colleges should be associated with the University in conducting the Preliminary Scientific, Intermediate, and Final Examinations for the Pass Degree (M.B., B.S., M.D.).

The objects of these arrangements are, as the delegates point out, to secure facilities to the average London student to obtain a medical degree; systematisation of medical education in London with a reduction in the number of examinations and a greater use of the magnificent opportunities of clinical study afforded by the London hospitals; and lastly economy.

The scheme proposed in this report was communicated to the University of London by letter addressed to the Chancellor by the Presidents of the Colleges early this year, and no doubt will be duly considered by the Royal Commission, recently appointed to inquire into the reconstituted university and now sitting.

(To be continued.)

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ANNUAL MEETING OF FELLOWS AND MEMBERS.

THE annual meeting of the Fellows and Members of the Royal College of Surgeons of England was held on Nov. 18th, Mr. Butlin, the President, being in the chair.

Some delay occurred in the commencement of the proceedings owing to the quorum of 30 required by the regulations not being present. When a quorum had been attained the PRESIDENT laid the report of the Council before the meeting and drew attention to several points contained in it. After remarking that 2652 copies of the report had been sent to Fellows and Members who had asked for it, he said that the final steps for the admission of women to the examinations for the diplomas of the College had just been completed. The next point concerned the proposed combination with the University of London. He said that the Senate had drawn up a scheme to permit of such a connexion, and the Council of the College had also formulated a scheme, but unfortunately differences, apparently irreconcilable, existed between the two schemes, and he felt somewhat pessimistic as to the probability of any such union taking place. However, a Royal Commission was at present sitting and it was possible that something might come of it. Remarking that the report of Dr. J. Ward Cousins, who was the representative of the College on the Central Midwives Board, would well repay perusal, the President gave a short sketch of the working of the Midwives Act since its passing in 1902 to the present time, and he lamented the lack of efficient provision for the payment of medical men called by midwives into difficult cases. He stated that there were many inconveniences in the Act, and that in July, 1906, Sir Henry Morris, who was then President of the College, had written to the Privy Council pointing out the desirability of making some provision for medical aid, and he had no doubt that before long an amending Act would be passed. During the year a number of valuable demonstrations had been given in the museum by Professor A. Keith, the conservator, and Professor Shattock, the pathological curator. These had been well attended and had been much appreciated and they had undoubtedly increased the utility of the museum. The establishment of these demonstrations had been mainly due to Mr. H. H. Clutton, whose loss they had all recently to deplore. He wished to draw particular attention to the section referring to the collection of odontological specimens, presented by the Odontological Section of the Royal Society of Medicine. The arrangement and the upkeep of this collection entailed a considerable expenditure both of money and labour, but its presence placed the museum of the College in the possession of what was probably the most valuable odontological collection in the world. As to the finance of the College, it might be said that it was satisfactory. He referred in detail to many of the items connected with the income and expenditure, and especially drew attention to the fact that by the successful sale of the examination buildings on the Victoria Embankment the loss on the original cost amounted only to £4000, and it must not be forgotten that the examination halls had been used for 22 years, and therefore as the lease was diminished to that extent the price obtained must be con-A large increase in the expenditure sidered satisfactory. had been connected with the changes in the museum. The

chief change had been the re-issue of the catalogue of the museum; many years had elapsed since the previous edition had been prepared, and during that time the additions to the museum had been very numerous, and more than 12 volumes of additions had been issued. After much consideration the card form of catalogue had been recommended by the museum committee and adopted, and the arrangement which was now being carried into effect was that the catalogue should consist of two parts. In the first place, in the museum itself near the specimens were placed many little boxes containing card descriptions of the specimens; secondly, in the hall of the museum was a series of cards which served as an index to the specimens by which it was possible to find the situation in the museum of any specimen which a visitor wished to examine. For the purpose of this large hall catalogue four cabinets had been designed by Mr. E. C. Frere, A.R.I.B.A. Altogether the improvement in the museum resulting from the formation of a new catalogue would be very great. He formally presented the report to the meeting.

Dr. W. G. DICKINSON asked permission to put a few questions. He wished to know what was meant by the body corporate on page 9, where it was stated that the property of the College is not vested in the existing Members.—The PRESIDENT, in reply, stated that the body corporate consisted of the past, present, and future Fellows and Members. -Dr. DICKINSON further inquired if he was to understand that any scheme for a combination of the College with the University of London had fallen through. - The PRESIDENT stated that until the report of the Commission at present sitting was issued no certain answer could be given. - Dr. DICKINSON further inquired in reference to the statement that Mr. Golding-Bird had been appointed to succeed Dr. Ward Cousins as the representative of the College on the Central Midwives Board, whether Mr. Golding-Bird had ever attended a midwifery case since he was a student, and if not how he could be a suitable member of a board that had to judge of the fitness of women to act as midwives.—The PRESIDENT pointed out that the late representative of the College had not practised midwifery for many years and yet had acted as a most satisfactory representative of the College on the Midwives Board.

Mr. F. W. COLLINGWOOD asked if there was any chance of the Council allowing the Members to have some voice in the management of the College affairs.

The PRESIDENT said that the matter had often been discussed on the Council, but that it had not been found possible to devise any satisfactory arrangement.

The PRESIDENT then called upon Mr. JOSEPH SMITH to introduce the first resolution, which was as follows:—

That this twenty-fifth annual meeting of Fellows and Members again affirms the desirability of admitting Members to direct representation on the Council, which as now constituted does not represent the whole corporation, and that it does so in order that the constitution of the Council of the Royal College of Surgeons of England shall be in keeping with modern ideas of true representation.

He observed that as a resolution almost identical with the present had been carried on 24 previous occasions it was so familiar to all present that it was unnecessary for him to say anything in regard to it. The vast majority of the Members supported some such scheme of representation, and many enlightened Fellows were also on their side. The Members contributed a large sum of money to the exchequer of the College, and where, he asked, would the College be without its Members? The President of the College was not really the President of the College—he was merely the nominee of the Council who were the nominees of the Fellows. It was high time that such an old-fashioned state of things should come to an end.

The motion was seconded by Mr. Collingwood, who pointed out the great moral claim the Members had to representation on the Council. The presence of Members on the Council would aid the deliberations of that body. For instance, if Members had been on the Council the question of the association of the College with the University of London, difficult question though it was, would have been settled long ago.

settled long ago.

Mr. A. N. WATTS stated that he became a Member in 1864, and from that time to the present he had never been asked to take part in any function connected with the College, except these annual meetings.

A MEMBER mentioned that the Council was not in touch with the Members, and when the Members met with

difficulties in connexion with their rights as Members they could not obtain the assistance of the Council. He mentioned that during the last two years he had practically been debarred from giving evidence in one county court because the judge would not allow him to swear on his own New Testament, and would not admit his evidence unless he swore on the Testament provided by the court.

Mr. H. ELLIOT-BLAKE pointed out that the presence of Members on the Council would bring the Members more closely into touch with the Council.

Mr. EDMUND OWEN said that the present powers were vested by Charter in the Fellows and the Council and by right of that Charter they exercised it.

Mr. C. C. MITCHINSON mentioned that during the 50 years he had been a Member the College had done nothing for him.

Dr. WALTER SMITH said that a house divided against itself must be weak, and the addition of Members to the Council would add to the strength of it.

Mr. ELLIOT-BLAKE pointed out that in the Charter the consent of the Members had not been asked.

A MEMBER claimed that the Members of the College, though they had passed examinations more difficult than those leading to degrees in some of the universities, were under practical disabilities in courts of law, as their evidence was supposed to be inferior in value to that given by doctors of medicine.

A MEMBER said that such resolutions as this were merely like whipping a dying horse.

The motion when put to the meeting was carried nemine contradicente.

The second motion was brought forward by Dr. A. S. MORTON; it was as follows:—

That in fulfilment of the promise made by the President of the College in 1905 this meeting strongly urges the Council to impress upon the Government the necessity of amending the "Midwives Act" next session, in order that provision may be made to secure just remuneration for professional services rendered by medical men under this Act.

He commenced by observing that three years ago he withdrew a similar motion because the President assured him that the question of payment would be considered. In the country Members were liable to be called long distances to attend women in labour, knowing all the while that they would be unable to obtain any remuneration for their work. If the Council of the College had not supported the Midwives Act it could not have become law. The Government had the lowest idea of the value of the services of medical men; it paid for the examination of a man for the Woolwich arsenal the magnificent sum of sixpence; and Mr. Haldane's territorial scheme provided that for the examination of recruits, including the examination of the heart and lungs, the eyesight, the teeth, the presence of varicose veins, recording the colour of hair, and of many other particulars, the medical officer should receive a shilling.

The motion was seconded by Dr. W. H. DAY, who pointed out that medical men were always expected to work for nothing. Death certificates had to be given without fee, and yet the Registrar was authorised to receive for a mere copy of that death certificate 2s. 7d., and now medical men were compelled to send notice of births also without charge.

A MEMBER said that the one important effect of the present arrangement was that now medical men only got the difficult midwifery cases, all the easier cases being attended by midwives.

Mr. COLLINGWOOD observed that the duties and responsibilities of the general practitioner were accumulating while the remuneration they were receiving was diminishing.

The PRESIDENT admitted fully the intense need that existed for a settlement of this difficult question, and he did not doubt that before long an amending Act would be passed, but the Government was never willing to pass an amending Act to an Act until some years had elapsed, so that the difficulties of the working of the Act should be fully ascertained before the amending Act was brought forward.

The resolution was carried unanimously.

The third motion was brought forward by Mr. Elliot-Blake; it was —

That the Council of the Royal College of Surgeons of England through their joint committee of delegates, and when it was found necessary and

in any agreement with the Royal College of Physicians of London, be asked to approve of and promote a new Charter and Act of Parliament to incorporate the Royal Colleges of Surgeons of England and Physicians of London, so as to form Royal Colleges or parts of the University of

He did not refer merely to the disabilities associated with the absence of the degree of Doctor of Medicine. His main argument was that the existence of such bodies as the Colleges was an anachronism, and that their existence should be merged in that of the University of London. They needed support of such a body as the University in the withered state of the College.

Mr. J. BRINDLEY JAMES seconded it.

Mr. COLLINGWOOD contrasted the arrangements in Edinburgh with those of London, and said that the present arrangements in London were utterly faulty, otherwise why should a town of only half a million inhabitants like Edinburgh have three times as many medical students as London, which had a population in itself twelve times as great.

Dr. DICKINSON would have liked some more information as to the number of University candidates who gained the diplomas of the College, and he was referred by the PRESIDENT to the report which contains the information for which he was asking.

The motion when put to the meeting was carried, with two dissentients.

A vote of thanks to the President for presiding was carried with acclamation.

Eleven Members of Council were present, five other Fellows, and 48 Members.

THE REPORT ON SCOTLAND OF THE ROYAL COMMISSION ON THE POOR-LAWS AND RELIEF OF DISTRESS.

THE Poor-law Commission in its report upon Scotland makes recommendations which follow the lines of those already published by it with regard to England and Wales, but which are necessarily modified and altered to suit the physical and economic conditions of the country to which they are to be applied. The existing Poor-law of Scotland, if it has grown up side by side with that of Kngland, has owed its inception and development to different Acts of Parliament and to administrative regulations differing from those which have been found appropriate to its neighbour south of the Tweed. These have been framed to suit the temperament and habits of its people, which are not the same as those of the English, and it need hardly be said that within the limits comprised under the title Scotland are found wider variations of circumstance due to geographical and climatic features than are presented by England and Wales. Scotland contains cities such as Edinburgh and Glasgow, fertile lowlands and prosperous country towns, together with highlands and islands, in which throughout large tracts the inhabitants live lives of great poverty and hardship, and in which sometimes medical aid for the poorer classes may fairly be said scarcely to exist at all. To a large section of those who read this latest Blue-book issued by the Commission the chapters relating to the conditions of medical Poor-law service will appear to be the most interesting, and to point to a state of affairs more urgently crying out for reform than the system of outdoor or indoor relief of those not in need of medical aid. The interest referred to should be roused not only in medical men but in all laymen who have the welfare of the Empire at heart and who desire to see their fellow subjects within its boundaries accorded a fair chance of surviving to be healthy and useful citizens. The Commissioners quote from the evidence of the late Dr. Macdonald of Stornaway with regard to one of the islands words which apparently are not wholly inapplicable to other districts: "I have visited the greater part of our vast Empire, but have yet to visit any part thereof in which British philanthropy has failed to put medical assistance and hospital treatment within easy reach of the poor as in Lewis; nay, more, that same philanthropy has extended the same privileges to poor people beyond the bounds of our Empire, so much so that, were some globe trotter to come across conditions

similar to those prevailing in Lewis a Mansion House fund would be inaugurated for their relief. But here in Lewis, within 24 hours journey of London, men, women, and children are allowed to die without adequate provision being made to bring medical assistance and hospital treatment within easy reach of them, and under sanitary conditions that had better not be described."

If we dwell upon the recommendations made by the Commissioners for the amelioration of the conditions of medical service throughout Scotland rather than upon their views with regard to the relief of distress generally, and upon those relating to the modification of unemployment, we must first briefly indicate the changes which they wish to see in the administration of relief to the destitute, and in the agencies through which that relief, including medical aid, should in their opinion be distributed. With regard to the central authority, the Commission recommends that the Local Government Board of Scotland should assume a more direct position of initiative and guidance in matters of principle affecting the administration of the Poor-law or, as they propose to call it, Public Assistance. With a view to make this possible, suggestions follow for raising the status of the Board, for increasing the number of superintendents of the poor, for increasing the powers of the Board, for improving the system of audit, and otherwise for rendering the Board effective in stimulating and directing the administration of Public Assistance.

In the administration of relief the Commission finds the parish and not, as in England, the union of parishes the unit of administration in Scotland. Distinguishing burghs with a population of 7000 and upwards from counties exclusive of these, it recommends that the area of the burgh should be the administrative area in the former case and that of the county in the latter, with powers of combination and cooperation in both cases where necessary in order to provide special institutions for particular classes of poor persons. For burghs having a population over 7000 it is recommended that there should be a Public Assistance Authority appointed by the town council and composed as to one half of town councillors and as to one half of persons of experience in the administration of Public Assistance and other cognate work, the whole forming a statutory committee of the town council. Burgh Public Assistance committees are recommended for the purpose of carrying out the work in divisions of the burgh where the formation of such divisions is found necessary, the committees to be appointed by the Public Assistance Authority, and to consist partly of members of it and partly of members of voluntary aid committees where such are found. Since 1894, under the Local Government (Scotland) Act, parish councils have taken the place of parochial boards (instituted in 1845) for the distribution of parish relief, and the Commission recommends that in burghs having a population of less than 7000 these should be retained for the purpose of public assistance in such burghs and in landward (rural) districts, acting under a county Public Assistance Authority, composed on lines nearly the same as those recommended for England. It adds, however, that the parish councils should be supplemented by persons having experience to be appointed to them by the ublic Assistance Authority.

It is recommended that a proportion of Public Assistance Authorities and of the committees should consist of women, and recommendations are made for the provision of officers to work under them and for improving the status and efficiency of these. The inspector of the poor is the officer chiefly dealt with, and it is mentioned that the only other Poor-law officer whose appointment is required by statute at the present time is the medical officer of a poorhouse.

The conditions of Poor-law relief in Scotland differ in

The conditions of Poor-law relief in Scotland differ in many particulars from those found in England. The qualification for poor relief in Scotland is destitution—i.e., poverty, not absolute destitution, combined with disability to earn a livelihood; i.e., bodily or mental incapacity. No others may be relieved, not even the sick dependents of an able-bodied man, or a man in bad health who is nevertheless able to earn wages. The Commission recommends an extension of relief to the necessitous whom it defines. In Scotland, as regards the sane poor the term "indoor relief" is applied only to the maintenance of poor persons in a prorhouse, all relief in other institutions being regarded as outdoor relief. After discussing the defects of poorhouses, which in Scotland are more easily filled in burghs than in

country districts, and are open to many of the objections which apply to general workhouses, the Commission recommends that the general poorhouses should be abolished and that institutional assistance should be given in separate institutions appropriate to the various classes for whom it may be necessary. The essential difference between Scottish and English Poor-law administration lies in the prevalence of outdoor relief—a term applied to all not relieved in a poorhouse. Outdoor relief is thus considered to be given to children maintained out of the rates in charitable institutions, but apart from this the proportion of outdoor relief will be appreciated when it is stated that on May 15th, 1908, it was ascertained that out of the total number of paupers (excluding lunatics) 84.81 per cent. were in receipt of it. The Commission finds that it is often not administered wisely and that its unconditional character causes it to have little curative or restorative power. The effect of this feature of almost universal outdoor relief upon the conditions of Poor-law medical service need hardly be pointed out. With regard to the aged not suited for assistance at home, the Commission recommends special institutions, advising the extension of "parish homes," of which it describes instances in Scotland in terms of commendation. the boarding-out of children to be well conducted in many places, but recommends that it should be more carefully regulated by the Local Government Board. It condemns their maintenance in poorhouses and gives instances to show that in Scotland this occurs under undesirable conditions. It also makes recommendations as to treatment by the Public Assistance Authority of unmarried women coming under it for the purpose of being delivered of illegitimate children in order that such treatment may tend to check immorality. For this purpose it points out the difference between those who become mothers for the first time and those who are mothers of illegitimate children already, and, again, those who are of weak intellect.

(To be continued.)

THE MEDICAL TREATMENT OF LONDON SCHOOL CHILDREN.

AFTER a protracted debate the London County Council on Nov. 30th approved the further arrangements for the medical treatment of London school children submitted by the Education Committee and referred to in THE LANCET of Nov. 6th, p. 1367. The committee recommended the Council to enter into agreements with eight hospitals to provide treatment for 16,000 children suffering from ailments of the eyes, ears, and skin, and to accept the offer of the Charing Cross Hospital to provide X ray treatment for 25 children suffering from ringworm. The committee also reported without comment the receipt of a resolution passed by the British Medical Association at Belfast, protesting against the procedure contemplated by the London County Council as unsound in principle and unjust to the medical profession.

The debate, which lasted for three hours, took place on the report as a whole, but the following amendments appeared on the agenda paper. By Mr. Bray:-

That the waiting-room and other accommodation is to be satisfactory to the Council, and the hours of treatment such as to be convenient to working-class parents.

By the Rev. Stewart Headlam :-

That in view of the great distances which many thousands of childrenespecially from South London, will have to travel to the hospitals, the
loss of time which the poorest parents will suffer owing to the long
waiting in the out-patients' departments, and the difficulty of ensuring
adequate treatment in such departments, which have so many other
patients awaiting treatment, the Council directs the Education Committee to prepare a definite scheme for the establishment of school
cllinics, so that the children can be attended to in their own localities.

Mr. CYRIL JACKSON, chairman of the committee, in introducing the report, referred to the decision of the Council earlier in the year to treat through the hospitals certain of the ailments from which children suffer. It was evident, he said, from the present report that they were able to deal with all the cases needing treatment in the existing institutions. With further proposals to come before the Council at a later date they would practically cover the whole of London. Only 5000 children still needed arrangements to be made for them

under the present reference to the committee. were one or two districts not served by the hospitals, notably Woolwich and Norwood, and there the committee was communicating with the local practitioners in the hope that suitable arrangements might be made. The Council owed a great deal to the education officer for the trouble he had taken. The negotiations with the hospitals were not easy owing to misunderstandings in the minds of the medical profession as to what the Council intended to do. Now this was better understood more and more hospitals were coming forward. Indeed, certain institutions had applied and had been refused because there were not enough children in their districts requiring treatment. Their services might be utilised later, but he did not think they would be required. He was certain the best method of dealing with the children was by the magnificent hospitals and their skilled staff. The Council would not be able to command the same class of men for clinics which it might establish.

The case against the committee's proposals was opened by Mr. Bray, who entered into a detailed comparison of the cost of clinics and treatment in other institutions. regarded the omission of dental treatment as very serious, and mentioned that only last week the Education Committee adjourned for another six months the consideration of this part of the question, notwithstanding that its attention had been called to it by various bodies. The military and naval authorities urged that the children's teeth might be attended to in order that recruits might be obtained more readily, and the medical profession warned them that many diseases originated in septic teeth. It would be possible to set up 12 clinics in convenient situations and treat every year 131,000 children at a cost of £20,000, or 24 clinics for £26,000. The cost per head would be not more than 4s. They were to pay the hospitals an average of 5s. a head, or 25 per cent. more than the sum for which they could do the work themselves. What value were they to get for the extra payment? The agreements to be entered into provided that the hours of attendance must be convenient to the hospitals, the additional clinical assistants would be appointed by the hospitals, and the Council would have no voice and no representation, and it agreed not to interfere in any way with the work of the department. Had the out-patient departments of the great hospitals been famous for their efficiency? Out-patients were treated in a way that would not be tolerated if the service were on other than a voluntary basis. He could not conceive that efficiency would result from handing their children over to these departments. The expense would be greater than the committee seemed to think. It might be said that the Council would save in the case of the hospitals which gave free treatment. was it likely that these hospitals would continue to do so when they knew they could get help from the rates and a promise on the part of the Council not to interfere with the management? Already the London Hospital, which promised free treatment, had asked for a grant. The Education Committee also calculated that many children would be treated free by the hospitals as at present. That might be so if the Council established clinics, but did anyone imagine the hospitals would agree to receive school children in regard to some of whom they would receive 5s. a head and in regard to others nothing. They would refuse to treat any school children except under the ægis of the London County Council. The result would be that the Council would have to pay for the maximum number of children. Further, the cost to parents living remote from the hospitals in taking their children to the out-patient departments for treatment would be considerable. In necessitous cases this would have to be paid by the Council, and in all cases where the cost of treatment was sought to be recovered allowance would have to be made as between parents living near and those living far from hospitals. The scheme, then, could not fail to be extravagant.

Mr. JAY said that nothing like a reliable estimate of the cost of school clinics had been before the committee and therefore he did not take Mr. Bray's figures seriously. cost as between the two proposals would not be appreciable. The committee had been able to tell the hospitals exactly how many cases would be sent to them and so they would be able to make precise arrangements for the dealing with them. No doubt the Council would have to pay fares in some cases and also make allowances towards the expenses of those living at a distance from the hospitals.

¹ THE LANGET, April 10th, 1909, p. 1069.

Mr. JEPHSON welcomed the scheme as far as it went. He believed a system of depending partly upon hospitals and partly upon clinics would be necessary, and that neither alone would solve the problem.

Mr. Cohen believed school clinics would be more expen-

sive than was generally supposed.

The Rev. STEWART HEADLAM wished that the Finance Committee, which was responsible for the curtailment of the scheme by the omission of the treatment of teeth, could be brought to realise the result to London in one generation if in the schools the children's ailments, fraught with such serious consequences, were attended to. They would then be eager and enthusiastic to spend whatever money was necessary to make the coming generation healthy. This was essentially the work of the Gospels—fighting against disease and for health—and the call came to them all to perform it. Mr. Headlam reminded the Council that the special committee, consisting of medical men and other experts, appointed to consider this question reported in favour of clinics. The British Medical Association had expressed the same opinion.

The Rev. Dr. SCOTT LIDGETT remarked that the hospitals were doing this work on their own terms, whereas the Council should have had some control where public money He feared that as the children were was being spent. more stringently inspected and disease long unsuspected was revealed, the pressure on the hospitals would cause the proposed arrangements to break down. Whole districts were left out, and nothing was done to minimise the hardship to parents in having to sacrifice their day's work to take their children to the hospitals. He did not want to speak lightly of the out-patient departments, but in them young, inexperienced men would see the children. Clinics seemed at least as economical, and in them the Council could engage a staff of higher medical skill than would be provided for the children in the hospitals. ("Oh.") Did members suppose that distinguished heads of the hospital staffs would be at the disposal of the children? They must recognise that while general instruction was given by these authorities, the bulk of the work would be carried out by those who had the minimum qualification for operating upon their fellow creatures.

Mr. GRAY declared that a proposal to spend many thousands of pounds upon the establishment of clinics and the provision of treatment for teeth would be unpopular with the London electorate.

Mr. CYRIL JACKSON, replying to the various points raised in the debate, said that the hospitals were making arrangements in many cases for separate treatment of the children to The committee was still prosecuting be sent to them. inquiries on the subject of dental treatment, and the education officer had been to Cambridge to inquire into the working of the dental clinic there. The cost was 7s. 2d. a head and the percentage of children with carious teeth was 76 per cent. Until it had fuller details the committee thought the Council should deal only with the ailments arising more particularly in connexion with school work.

The amendments on being put to the vote were both lost, as was also a proposal by Dr. R. M. Beaton to instruct the committee to report forthwith as to the provision of dental The recommendations of the committee were treatment. then agreed to.

CENTRAL MIDWIVES BOARD.

A MEETING of the Central Midwives Board was held at Caxton House, Westminster, on Nov. 25th, Dr. F. H. CHAMPNEYS being in the chair.

Mr. E. PARKER YOUNG moved:

That one member of the Central Midwives Board be elected as a Direct Representative by the registered medical practitioners in England and Wales in the same manner and at the same time as the Direct Representatives on the General Medical Council are elected.

He said that there were three Direct Representatives of the medical profession on the General Medical Council, and in the future there was going to be a fourth. In regard to the representatives on the Central Midwives Board the medical representatives were sent up to the Board through the examining bodies by a small number of persons. It was clear there was no direct representation on the Central |

Midwives Board, and if such representation was good for the General Medical Council surely it must be good for the Central Midwives Board.

Dr. S. B. ATKINSON, in seconding the motion, pointed out the advisability of the general practitioner voting at the same time for the General Medical Council and the Central Midwives Board.

The motion was put to the vote and carried.

A letter was received from the National Association of Midwives claiming to appoint a representative on the Board. The Board approved of the reply sent by the secretary stating that the Board had no power in the matter.

The Standing Committee reported that a letter had been received from the medical officer of health of Bolton as to the dismissal of a midwife from further attendance on a case by a registered medical practitioner who had been summoned on her advice. The committee recommended that the reply be that, on the facts stated, the Board considers: (a) That it would not have been right for the midwife to have disobeyed the instruction of the medical man, and to have kept on with the case until she had received notice from the local responsible for the case, his orders, however ill considered, must be obeyed (Rule E, 6). (c) That as regards the question of suspension of the midwife to avoid spreading infection this was not necessary.

Miss R. PAGET protested against the recommendation because, in her opinion, it set up a precedent giving the right to medical men to send away midwives from their

Sir GEORGE FORDHAM objected to the recommendation because he did not think it was necessary to lay down rules of conduct.

On the motion of Dr. ATKINSON the previous question was

put and carried, and the subject dropped.

A letter was considered from Miss F. Bernard-Boyce, inspector of midwives for Norfolk, as to the extent of the right of a midwife to administer drugs. The Board decided that a reply be sent embodying the principles laid down in a circular letter to the examiners dated June 8th, 1907, on the subject of the administration of drugs by midwives, giving details as to the rules authorised for the proper administration of drugs by midwives under safeguards. the course of the discussion on this matter Mr. GOLDING-BIRD stated that he did not consider that the term "administering a drug" meant prescribing one.

A letter was received from the honorary secretary of the Chelsea Division of the Metropolitan Counties Branch of the British Medical Association, forwarding a copy of a resolu-tion passed at a meeting of the medical practitioners of Chelsea and Fulham, refusing to attend women in, or immediately after, childbirth, or in respect of puerperal maladies, in response to emergency calls by midwives, unless the boards of guardians of Chelsea and Fulham guarantee to pay the fee.

BRITISH MEDICAL BENEVOLENT FUND.

At the November meeting of the committee of this Fund 27 cases were considered and grants amounting to £271 were made to 23 of the applicants, three cases being passed over as unsuitable for help and one case postponed for further inquiry. Appended is an abstract of the cases relieved:

inquiry. Appended is an abstract of the cases relieved:

L.S.A., aged 65 years. Used to have a fair practice, but lost it through ill-health and other misfortunes and has had to start afresh in a neighbourhood where the fees are extremely small and the competition very severe. Is making progress, but requires a little help. Relieved once. £18. Voted £18 in 12 instalments.

Widow, aged 64 years, of M.R.C.S., L.S.A. Since husband's death. 24 years ago, has supported herself until recently, but now finds it very difficult to obtain work, and is not in very good health. Relieved once. £12. Voted £12 in 12 instalments.

Wife, aged 64 years, of M.R.C.S. Was deserted by her husband six years ago through no fault of her own and is now destitute and in very feeble health. No friends or children able to help. Relieved twice, £24. Voted £12 in 12 instalments.

L.R.C.P., L.R.C.S.I., aged 62 years. Practised for many years in the North of London, but lost all his patients through gradual failure of health and is now quite incapacitated. No children; no income and help given by friends during the last year is obliged to be withdrawn. Voted £18 in 12 instalments.

Daughter, aged 48 years, of late M.R.C.S., L.S.A. Was obliged to yilve up a good post as governors to nurse her mother during an illness which continued many years, and now needs a rest before again endeavouring to find employment. Income only a few shillings a week. Voted £5 in one sum

Daughters, aged 59 and 50 years, of late M.R.C.S. Since father's sudden death more than 30 years ago have endeavoured to support themselves by receiving paying guests at a small house of which they are the owners. Are obliged to ask help for the winter owing to the expenses arising from a severe accident to the elder applicant. Voted £10 in one sum.

are the owners. Are oblight to ass help for the winter owners at the expenses arising from a severe accident to the elder applicant. Voted £10 in one sum.

Widow, aged 63 years, of M.R.C.S., L.S.A. Maintained herself as a nurse-companion for many years, but is now practically destitute. Receives a few shillings occasionally from a son recently made a bankrupt, and earns about a shilling a week by glove cleaning. Voted £12 in 12 instalments.

Widow, aged 68 years, of M.R.C.S., who practised in London, but was incapacitated owing to ill-health and supported for several years by the applicant. No income and dependent on a son-in-law who can ill afford to help. Voted £10 in two instalments.

Widow, aged 68 years, of L.R.C.P. Edin., M.R.C.S. Eng. No income; children unable to help; health failing. Relieved twice, £24. Voted £12 in 12 instalments.

Daughter, aged 58 years, of late M.D. Lond. No income; endeavours to support herself by letting lodgings and by needlework; eyesight defective. Relieved 26 times, £196. Voted £6 in six instalments.

Widow, aged 72 years, of M.D. Lond. Only income two small annuities and asks for a little help to obtain little comforts necessitated by her advanced age. Relieved four times, £26. Voted £5 in one sum.

Daughter aged 55 years of late M.D. L.S.A. Was a governess for

sum.

Daughter, aged 55 years, of late M.D., L.S.A. Was a governess for many years, but is now in ill-health and quite unfitted to earn her living. Relieved eight times. £20. Voted £12 in 12 instalments.

Daughter, aged 53 years, of late M.D. Edin. No income; endeavours to support herself by taking lodgers, but has had a very bad season. Relieved twice £12. Voted £10 in one sum.

Widow, aged 55 years, of M.B. Cantab. Quite unprovided for at husband's sudden death about seven years ago and has since endeavoured to support herself by taking in washing and acting as charwoman. Has two daughters in domestic service and is advised by one of them in Australia to go out there with the youngest child, aged 9. Relieved six times, £77. Voted £5 temporarily and promised £12 towards passage money if friends find the balance.

Widow, aged 49 years, of L.S.A. Left quite destitute at husband's

passage money if friends find the balance.
Widow, aged 49 years, of L.S.A. Left quite destitute at husband's death from new growth a few years ago and dependent on a son aged 17, earning 15s. a week. Health feeble; very deaf; has lost her sight in one eve and is nearly blind in the other. Relieved four times, £50. Voted £12 in 12 instalments.
Widow, aged 53 years, of L.F.P.S.Glasg. No income: slight help from elder children. but has three dependent on her, the youngest having spinal curvature. Relieved three times, £36. Voted £12 in 12 instalments.

Widow, aged 50 years, of L.S.A. Two daughters, aged 17 and 15. Has endeavoured to support herself and them by letting lodgings, but has been obliged to sell most of her furniture. Relieved twice, £20. Voted £12.

Daughters, aged 57 and 52 years, of late M.R.C.S. Small earnings from needlework and slight help from friends. Relieved five times, £56.

from needlework and slight help from friends. Relieved five times, £56. Voted £18. Widow, aged 75 years, of M.R.C.S. Has an Epsom College pension and receives a little help from a son, but has been obliged to incur heavy expenses for a daughter who has recently undergone a severe operation. Relieved seven times, £68. Voted £10.

Daughter, aged 62 years, of late M.R.C.S. Assisted her mother to keep a boarding-house for 13 years in order to support her father, who was paralysed, and now acts as housekeeper to two sisters who are endeavouring to establish a school. Relieved once, £12. Voted £12.

Daughter, aged 51 years, of late M.R.C.S. Nursed her father, who was a pensioner of this Fund and Epsom College, for 10 years, and now finds it very difficult to obtain sufficient work to support herself. Relieved once, £12. Voted £12.

L.R.C.P., L.R.C.S. Edin., aged 52 years. No income; has been incapacitated by spastic paralysis for several years. Relieved five times, £60. Voted £12.

Daughter, aged 49 years, of late M.R.C.S. Eng., L.R.C.P. Edin. No

Daughter, aged 49 years, of late M.R.C.S. Eng., L.R.C.P. Edin. No income and has recently undergone a severe abdominal operation. Relieved once, £12. Voted £12.

Contributions may be sent to the treasurer, Dr. Samuel West, 15, Wimpole-street, London, W.

Looking Back.

PROM

THE LANCET, SATURDAY, Dec. 3rd, 1831.

Researches to establish the Truth of the Linnaan Doctrine of Animate Contagions, wherein the Origin, Causes, Mode of Diffusion, and Cure of Epidemic Diseases, Spasmodic Cholera. Dysentery, Plague, Small-pox, Hooping-Cough, Leprosy, No. So., are illustrated by Faots, from the Natural History of Markind, of Animals, and of Vegetables, and from the Phenomena of the Atmosphere. By ADAM NEALE, M.D., &c. &c. 8vo, pp. 258. London: Longman and Co. 1831.

In the introduction to the present work, Dr. Neale informs us that "he has ventured to come forward as an advocate of the truth of the Linnean doctrine of animate contagions, believing that it is founded on facts, and on the ever-lasting nature of things, and that by its development alone physicians will be at length directed to the true method of curing diseases." Proceeding with these views, it

multitude of curious facts in natural history to bear upon. and apparently corroborate, his favourite hypothesis. Everything that is obscure in the diffusion of epidemics, and in the cure of almost innumerable disorders, he lights up by the assistance of his insect coadjutors; and not content with this, he even directs their energy to the overthrow of some old and seemingly satisfactory doctrines which that arch deceiver "common sense" had applied to the explanation of various items in the history of disease. For the entertainment of our readers, we shall quote a few of the anecdotes with which the volume abounds. Speaking of the plague, Dr. Neale states, p. 36:-

"Our knowledge of plague, after remaining for a long period in a very

"Our knowledge of plague, after remaining for a long period in a very uncertain state, was destined to be augmented and rendered more accurate by the plague having been unluckliy imported some years since (1831) into Malta, where it showed itself amongst the inhabitants first, and finally was communicated to some soldiers of the British garrison, then in Valetta."

"Sir A. B. Faulkner, then physician to the forces in the island of Malta, has published an account of this epidemical visitation. From his volume we select the following case, which occurred to Mr. Stafford, a regimental surgeon, who attended the man. Its date was the 16th of July, 1813, and the name of the sufferer was Robert Clark, aged about 24. Spare habit, lively disposition—had never been in hospital previously—had mounted guard this morning, after a minute naked inspection, when not a suspicious spot was to be seen on his body or extremities. His feet and hands had been carefully washed. About noon, Mr. S. says, I was sent for to visit him, he having been taken suddenly lame, while on sentry. On examining him, I found a small pimple in appearance, between the large and next toe of the right foot. The pain he declared to be excessive, and likened it to a burning coal. Whilst inspecting it, I could discover rising from it a red streak, which speedily ascended up the inside of the leg: and very soon after, a swelling took place in the inferior inguinal gland."

We need not quote the ensuing description of the disease,

We need not quote the ensuing description of the disease, as it differs in no respect from ordinary plague cases. But the really interesting part of the narrative is as follows :-

"His description of the first attack was this: -that he was standing "His description of the first attack was this:—that he was standing sentry on the top of the arch, through which was the only passage from the city of Valetta, into the country: that a pest-cart had that instant passed through heavily laden with dead bodies, from which proceeded a horrid smell: that the attack was instantaneous, as though he had been shot. I was instantly sent for, and was with him within three minutes, my quarters being near his post. My opinion (Mr. Stafford says) was, that from some defect in his shoe, some pest dust had got in, and was the true cause of his complaint. He had mounted guard at 7 o'clock in the morning, and had marched half a mile from his barrack to his post. to his post.
"Now, as Mr. Stafford does not inform us what that is which he calls

row, as Mr. Stanford does not inform as what that is wind the calls produce such an effect, I think we are fully warranted in concluding that this pimple on the foot had been caused by the stiny of something tiring, and that this living substance was, in fact, an insect of some sort, which had escaped from the dead bodies contained in the pest cart, as it passed beneath the arch, and which slung the sentry in the foot, as just stated!!"

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 76 of the largest English towns 7648 births and 5167 deaths were registered during the week ending Nov. 27th. The annual rate of mortality in these towns, which had steadily increased in the four preceding weeks from 12.0 to 14.6 per 1000, further rose to 16.4 in the week under notice, and exceeded the rate recorded in any week since the middle of April last. During the first eight weeks of the current quarter the annual death-rate in these towns averaged 13.4 per 1000, and in London the mean rate during the same period was 13.2. The lowest annual rates of mortality recorded in the 76 towns last week were 8.2 in Reading, 8.6 in Bournemouth, 8.9 in Handsworth, and 9.9 in Barrow-in-Furness; the rates in the other towns ranged upwards, however, to 26.5 in Wigan, 27.3 in Hanley and in Merthyr Tydfil, and 29.2 in Swansea. In London the recorded death-rate last week was equal to 15.6 per 1000. The 5167 deaths registered in the 76 towns last week showed a further increase of 561 upon the numbers returned in the four preceding weeks, and included 278 which were referred to the principal epidemic diseases, against 261 and 281 in the two preceding weeks; of these 278 deaths, 61 resulted from whooping-cough, 58 from diphtheria, 55 from diarrhoea, 44 from measles, 41 from scarlet fever, and 19 from "fever (principally enteric), but not one from small-pox. annual death-rate from these epidemic diseases last week was equal to 0.9 per 1000, against 0.8 and 0.9 in the two previous weeks. No death from any of these epidemic diseases was registered last week in Cardiff, Gateshead, is singular with what ingenuity Dr. Neale has brought a Brighton, Derby, Preston, or in eight other smaller towns;

the annual death-rates therefrom ranged upwards, how-Tydfil. The deaths from whooping-cough in the 76 towns, which had been 31, 48, and 69 in the three preceding weeks, declined again to 61 last week; the highest approach to the state of th annual rates from this disease during the week were 1 2 per 1000 in Aston Manor, 1.3 in Merthyr Tydfil, and 1.5 in Hastings. The 58 deaths referred to diphtheria showed a further increase upon recent weekly numbers, and included 20 in London and its suburban districts, 3 in Portsmouth, 4 in Manchester and Salford, 5 in Birmingham and King's Norton, and 2 each in Plymouth, Bristol, and Nottingham. The 55 deaths attributed to diarrhoea showed a further considerable decline from the numbers in recent weeks. The 44 fatal cases of measles were within one of the number in the previous week; the highest annual rates from this disease last week were 1.6 in Swansea, 2.3 in Hanley, and 2.7 in Northampton. The deaths from scarlet fever, which had been 44 and 28 in the two preceding weeks, rose again to 41 last week, and showed the greatest proportional fatality in Wigan and and the States proportion rate of the Yellow in Merthyr Tydfil; 11 fatal cases were recorded in London and its suburban districts, 6 in Manchester and Salford, and 4 in Sheffield. The 19 deaths referred to "fever" corresponded with the number in the previous week. The number of scarlet fever patients under treatment in the Metropolitan Asylums and London Fever Hospitals, which had declined during the six preceding weeks from 2810 to 2606, had further fallen to 2158 on Saturday last; 264 new cases of this disease were admitted to these hospitals during last week, against 284 and 308 in the two preceding weeks. The Metropolitan Asylums Hospitals contained 4 cases of small-pox on Saturday last. Of the 1442 deaths registered in London last week, 387 were referred to pneumonia and other diseases of the respiratory system, against numbers increasing from 167 to 283 in the six preceding weeks; these 387 deaths exceeded by 15 the corrected average number in the corresponding week of the five years 1904-08. The causes of 48, or 0.9 per cent., of the deaths registered last week in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death registered last week were duly certified in London, Leeds, Bristol, Newcastle-on-Type, Nottingham, Leicester, and in 44 smaller towns; the 48 uncertified causes of death in the 76 towns last week included 9 in Liverpool, 7 in Birmingham, and 3 in Gateshead.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 849 births and 866 deaths were registered during the week ending Nov. 27th. The annual rate of mortality in these towns, which had steadily increased in the four preceding weeks from 12.9 to 19.8 per 1000, further rose to 24.2 in the week under notice. During the first eight weeks of the current quarter the annual death-rate in these Scotch towns averaged 15.7 per 1000, and exceeded by 2.3 the mean rate during the same period in the 76 largest English towns. The annual death-rates last week in these Scotch towns ranged from 11.5 and 13.4 in Greenock and Leith, to 18.8 in Edinburgh and 32.7 in Glasgow. The 866 deaths from all causes in the eight towns last week showed a further increase of 158 upon the numbers returned in the four preceding weeks, and included 98 which were referred to the principal epidemic diseases, against 66 and 77 in the two previous weeks. These 98 deaths were equal to an annual rate of 2.7 per 1000; the mean rate from the same diseases last week in the 76 English towns did not exceed 0.9 per 1000. The 98 deaths from these diseases in the Scotch towns last week included 49 from measles, 16 from diarrhea, 13 from diphtheria, 9 from whooping-cough, 7 from scarlet fever, and 4 from "fever," but not one from small-pox. The fatal cases of measles which had been 24, 22, and 36 in the three preceding weeks, further rose last week to 49, of which 45 occurred in Glasgow and 4 in Edinburgh. The 16 deaths attributed to diarrhoea showed an increase of six upon the number in the previous week, and included 8 in Glasgow, 4 in Edinburgh, and 2 in Paisley. The 13 deaths referred to diphtheria exceeded the numbers in either of the two preceding weeks; 6 were recorded in Glasgow, 4 in Edinburgh, and 2 in Aberdeen.

7 deaths from scarlet fever occurred in Glasgow. The 4 deaths referred to "fever" included 3 in Glasgow certified as enteric, and 1 from cerebro-spinal meningitis in Edinburgh. The deaths referred to diseases of the respiratory system in the eight towns, which had increased in the four preceding weeks from 68 to 195, further rose last week to 298, and exceeded by 165 the number registered in the corresponding week of last year. The causes of 28, or 3 · 2 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 76 English towns the proportion of uncertified causes of death last week did not exceed 0 · 9 per cent.

HEALTH OF IRISH TOWNS.

In 22 town districts of Ireland, having an estimated population of 1,142,308 persons, 563 births and 460 deaths were registered during the week ending Nov. 27th. The mean annual rate of mortality in these towns, which had steadily increased in the fivepreceding weeks from 14.8 to 20.0 per 1000, further rose to 21.0 in the week under notice. During the first eight weeks of the current quarter the annual death-rate in these Irish towns averaged 17.4 per 1000, whereas the mean death-rate during the same period did not exceed 13.4 in the 76 largest English towns, and 15.7 in the eight principal Scotch towns. The annual death-rate last week was equal to 20.7 in Dublin (against 15.6 in London), 22.5 in Belfast, 26.0 in Cork, 13.3 in Londonderry, 16.4 in Limerick, and 25.3 in Waterford; the mean rate last week in the 16 smallest of the Irish town districts was equal to 18.9 per 1000. The 460 deaths from all causes in the 22 town districts last week showed a further increase of 21 upon the numbers returned in the five preceding weeks, and included 21 which were referred to the principal epidemic diseases, against 20 and 18 in the two previous weeks; these 21 deaths were equal to an annual rate of 1.0 per 1000; in the 76 English towns the mean rate from the same diseases last week was 0.9, and in the eight principal Scotch towns was 2.7 per 1000. The 21 deaths from these epidemic diseases in the Irish towns last week included 8 from whooping-cough, 6 from diarrhoea, 2 each from measles, scarlet fever, and enteric fever, and 1 from diphtheria, but not one from small-pox. The 8 fatal cases of whooping-cough exceeded by 2 the number in the previous week, and included 7 in Belfast. The 6 deaths attributed to diarrhoea, of which 3 occurred in Dublin, showed a further decline from the numbers in recent weeks. The 2 fatal cases of measles and 1 of the 2 deaths from scarlet fever occurred in Dublin. Of the 2 deaths from enteric fever, 1 each was returned in Dublin and in Cork. The deaths referred in the 22 towns to pneumonia and other diseases of the respiratory system, which had steadily increased in the five preceding weeks from 50 to 110, declined to 101 last week. The causes of 12, er 2.6 per cent., of the deaths registered in these Irish towns last week were not certified by a registered medical practitioner or by a coroner; in the 76 English towns the proportion of uncertified causes of death last week did not exceed 0.9 per cent., while in the eight Scotch towns it was 3.2 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointment is notified:—Staff-Surgeon F. F. Lobb to the Victory, additional, for disposal.

ROYAL ARMY MEDICAL CORPS.

Colonel F. B. Maclean has been appointed Principal Medical Officer, 7th (Meerut) Division, vice Colonel O. E. P. Lloyd, V.C., promoted Surgeon-General and appointed Principal Medical Officer, South Africa. Lieutenant-Colonel H. J. Fletcher will officiate as Principal Medical Officer, Abbottabad and Sialkot Brigades, vice Colonel Lyons, I.M.S.

INDIAN MEDICAL SERVICE.

Paisley. The 13 deaths referred to diphtheria exceeded the numbers in either of the two preceding weeks; 6 were recorded in Glasgow, 4 in Edinburgh, and 2 in Aberdeen. All the 9 fatal cases of whooping-cough and 5 of the Government of Burma, has been permitted to return to duty

within the period of his leave. Captain A. D. White has been appointed as a specialist in advanced operative surgery, 8th (Lucknow) Division.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Supplementary List: The undermentioned to be Lieutenants (on probation): George Rollason (dated Oct. 25th, 1909) and John Fraser (dated Nov. 1st, 1909).

TERRITORIAL FORCE.

Royal Army Medical Corps.

3rd North Midland Field Ambulance: Lieutenant George J. S. Atkinson resigns his commission (dated Oct. 23rd, 1909).

Attached to Units other than Medical Units.—Captain James H. Hunter resigns his commission (dated Oct. 15th, 1909).

HONORARY SURGEON TO THE KING.

Surgeon-General William L. Gubbins, C.B., M.V.O., Deputy Director-General, Army Medical Service, has been appointed an Honorary Surgeon to the King, vice Brigade Surgeon-Lieutenant-Colonel and Brevet Colonel C. E. Harrison, C.V.O., retired.

THE SECUNDERABAD GARRISON.

The Secunderabad correspondent of the Pioneer of Oct. 29th states that "There left by Calcutta mail to-day Lieutenant-Colonel E. Butt, R.A.M.C., who has just vacated the senior medical officership of Secunderabad station hospital on promotion as P.M.O Calcutta Colonel Butt has only been a few months in Secunderabad, but in that time he has accomplished some remarkable improvements in sanitation and reduced to a minimum diseases which for years have been very prevalent in the garrison here. The garrison is, in fact, in a healthier condition than ever it has been before. Whereas the prevalence of enteric fever had battled the skill of many of his clever predecessors, there have only been three cases since Colonel Butt's advent. The remarkable declination in disease is due to Colonel Butt's method of going to the root of sanitary evils, and although the troops were at first inclined to resent the rigorous measures adopted, all admit now that his methods have had a miraculous effect. Colonel Butt was the recipient of many farewell dinners, and his departure is much regretted.'

THE ARMY AND NAVY MALE NURSES' COOPERATION.

The second annual meeting of the Army and Navy Male Nurses' Cooperation, of which Her Majesty the Queen is patroness, was held at the Grafton Galleries, Piccadilly, on Nov. 29th, when Princess Louise, Duchess of Argyll, who was accompanied by the Duke of Argyll, was present. Sir William H. Allchin, in presenting the annual report, said that very satisfactory progress had been made during the year. The number of cases nursed was 300, being an increase of 108 over the previous year. The great progress that had been made was due in a large measure to the sympathetic attitude of the medical profession, and he hoped that the cooperation would soon be placed on a self-supporting basis. The Queen had shown her practical sympathy by sending a donation of £100. The War Office and the Admiralty had also greatly assisted the movement. The honour of founding the society belonged to Miss Ethel McCaul. aided by Sir Frederick Treves, and the cooperation of the heads of the medical departments of the navy and the army had enabled the committee to supply the public with suitable and reliable male nurses. The Duke of Argyll expressed the great interest which the Princess took in the work, and remarked on the necessity of preventing men who had obtained good nursing experience from drifting into the ranks of the unemployed. Colonel Sir Edward Ward, in the unavoidable absence of Sir Alfred Keogh, Director-General of the Army Medical Service, thanked Her Royal Highness for her interest in the work of male nurses, and said that Mr. Haldane and his colleagues at the War Office were deeply interested in the movement. Inspector-General J. Porter, the Director-General of the Medical Department of the Royal Navy, who followed, said that the nurses trained in the navy were second to none. He hoped that the cooperation would soon have three or four hundred nurses, who as reserve men would be able to help the country in time of need.

Correspondence.

"Audi alteram partem."

STATUS LYMPHATICUS.

To the Editor of THE LANCET.

SIR,-My services, as a medical expert witness, having been requisitioned by Messrs. McKenna and Co., solicitors for Messrs. Harrods, Limited, who were instructed to defend the case of Rex r. Clarke and Eardley re the sudden death of Miss Helenora Catherine Horn-Elphinstone Dalrymple while undergoing a dry shampoo with carbon tetrachloride on July 12th, 1909, and the case for the prosecution having now been withdrawn after a protracted hearing, for certain reasons to follow, I find myself prompted to write this letter for publication. The objects of such a prosecution are, of course, not a matter for me, and I only desire to deal with the case from a medical point of view. With regard to the danger of the use of carbon tetrachloride there can be no question about this or about the inadvisability of such "shampooing" being administered to any member of the public who likes to ask for it, but, in the particular case in point, had the defence been heard, I think it would have served to bring home a very important object-lesson to the medical profession—namely, that the status lymphaticus problem is a much more serious one than the majority suppose. It seems apparent to me and to others that the prosecution in furthering its objects lest sight of the all-important status lymphaticus factor. True, these desirable objects may have been attained and a warning note sounded to the hairdressing trade, but this has, in my opinion, only been accomplished by practically overlooking the "real" cause of death namely, lymphatism.

Doubtless there are cases in which people have been convicted of very serious charges when, in fact, death was due to this disease, and a number of cases are on record where nursemaids or relatives have been charged with suffocating or fatally maltreating children, the true cause of death found at the necropsy being lymphatism. The presence post mortem of the typical pathological picture of the disease justly should be prima-facie evidence of death from natural cases. In these days of deaths under anæsthetics the investigation of the disease is of the utmost importance, and I feel thoroughly convinced that if a Royal Commission should be appointed, as has been mooted, for the investigation of the subject, the status lymphaticus problem will be found to be one of the most important it will have to contend with. As it is, when one of these unfortunate tragedies occurs in the practice of a medical man with limited experience aspersions are sometimes cast on his professional capabilities, and probably an irreparable stain on his character results. For over three years now I have constantly given a great deal of thought to the subject. Very little is written or known about the disease, but on every possible occasion I have gathered all the information I could. Having personally met with six cases of sudden death from it in two and a half years, and in most of these instances having myself known and physically examined the subjects during life and made the post-mortem examinations after death, I have been able to draw certain deductions. I wrote a paper on the subject which was published in THE LANCET of Dec. 26th, 1908, and Jan. 9th, 1909, headed "Clinical and Post-mortem Observations on the Status Lymphaticus, with Deductions, and a Plea against the Maligning of Ethyl Chloride as a General Anæsthetic," and also another article to the Journal of the Medico-Psychological Association entitled "The Clinical and Post-mortem Aspects of the Status Lymphaticus," which was published in their quarterly journal of July, 1909. Notes, both before and after death, of all six cases are fully reported in these papers. The existence of the status lymphaticus undoubtedly in large measure accounts for the partial disrepute into which ethyl chloride has temporarily fallen, and its existence, too, has in certain circumstances brought ill-repute to a practice of such national importance as vaccination. I have known of such cases. For these reasons, also, it is a great pity that the status lymphaticus factor in "the fatal shampoo case" should not have been more fully discussed. I quite recognise the

raison d'être of the prosecution, but I cannot help thinking that on the all-important medical point above alluded to the evidence was misconceived, and this is one of the principal reasons which prompt me to write this letter; and here again I would like to emphasise the fact that it is to be construed in nowise controverting the undisputed toxicity of commercial carbon tetrachloride.

The question was, "What was, very roughly, likely to have been the actual volume of vapour given off and remaining in the cubicle at Messrs. Harrods at the time when Miss Dalrymple was being shampooed?" And this would depend mainly upon five factors—viz., (1) the area of evaporating surface; (2) the temperature of the room; (3) the velocity, direction, and area covered by the evaporating draught; (4) the size and position of the exits for escape of the vapour; and (5) the time during which evaporation was taking and (5) the time during which evaporation was taking place. Professor Pepper stated in his evidence that "the thought death was due partly to the heart and partly to the respiration, partly by the carbon tetrachloride acting as a poison on the heart, and partly by its effect on respiration." From the latter half of this opinion my convictions compel me to dissent, and I mention the fact because there is no disease of greater medico-legal importance than the status lymphaticus. In the case in question there was reasonable evidence to show that Miss Dalrymple's life was extinct before she was laid on the floor. The sequence of events at the catastrophe and even the post-mortem facts, as recorded at the inquest, strongly support such a view. I do not believe that Miss Dalrymple could have breathed any carbon tetrachloride vapour, and when making such a definite statement I at least feel that I have substantial reasons for doing so. would like it to be clearly understood, too, that my purpose in attempting to prove this, and that Miss Dalrymple's death was due entirely to lymphatism plus the effect of shock, is ostensibly for the sole object of drawing attention to this ill-understood disease instead of otherwise allowing it to received another set-back.

On Tuesday, Sept. 21st, I made certain experiments at Messrs. Harrods, Limited, in the room in which, I understand, Miss Dalrymple's death took place. In one experiment I requested that Miss Beatrice Clarke should have her hair dry-shampooed with tetrachloride in my presence, and that everything should be arranged and done exactly as it was in Miss Dalrymple's case. I particularly noticed the moment the vapour reached Miss Clarke's nose and mouth, and to achieve this end I kept my nose just in front of Miss Clarke's nose and mouth for the first four or five minutes, until the whole of 16 ounces of the carbon tetrachloride solution had been used, and the shampooing process practically completed. I was satisfied that I could detect no trace of tetrachloride vapour for the first three or four minutes at least, and that none could have reached Miss Clarke's face during this periodi.e., till the whole of the 16 ounces had been used-and I was prepared to state this fact on my sworn testimony. After this period, and if the door of the cubicle was closed, it was possible, and indeed most probable, that some of the vapour would reach the face of the person being shampooed (for quite explicable reasons), but this is entirely another matter. The ventilation of the actual cubicle was excellent. The fan used for the purpose of blowing the tetrachloride fumes away from the face of the person being shampooed was situate on her left side front, and the cylindrical tube, through which the blast of air was fired, was of about 3 inches in diameter, the nozzle of which would be approximately 3½ feet distant from the face of the person being operated upon and its direction in adjusted alignment with her head and the open door of the cubicle a few feet beyond. As the area covered by the current at 3½ feet forms a circle of just over a foot in diameter, and which circle coincides with the face, it is impossible to conceive how the vapour could fight its way in the teeth of such a gale, and get from the back of the head to the front of the face, not even from the hair just over the forehead, since in the shampooing position the latter is in a plane posterior to that of the nose and mouth. I understand that carbon tetrachloride was being used in numerous ladies' hairdressing establishments all over London, and in many instances where

nothing like such elaborate precautions obtained.

On my interrogation of Miss Beatrice Clarke I elicited from her that the sequence of events at the tragic catastrophe, as she observed them, was as follows. The first

thing that Miss Clarke noticed was Miss Dalrymple's hands falling limply from her face. This occurred approximately about one to two minutes only after commencing to pour the solution on her hair, and when about 4 ounces only of the tetrachloride solution had been used. Miss Dalrymple was at the time holding a small towel over her forehead, and this of course, falling with her hands, disclosed the next thing which Miss Clarke noticed in the looking-glass opposite them both—namely, that Miss Dalrymple was looking very pale. Miss Dalrymple had previously looked rather pale, but her pallor was much increased. Miss Clarke states that almost immediately after this observation the pallor suddenly became extreme, and Miss Dalrymple's head and body at the same time fell forwards. Miss Clarke at once tried to steady her, but found that she was unable to do this owing to Miss Dalrymple's general and very marked limpness, and it was at this stage that Miss Clarke became alarmed. Being unable to prop her up, she laid her on the floor and ran out of the cubicle for assistance. Miss Clarke hurried back in a comparatively few seconds, and then noticed a dusky leaden blueness about the face, and Miss Clarke further volunteered that this peculiar blueness was more noticable at the back of the neck-Miss Dalrymple was at the time laid on her back. Miss Clarke neither saw nor heard any breathing movements, and did not notice whether the pupils of Miss Dalrymple's eyes were either large or small, nor does she know whether her eyes were light or dark. Miss Clarke states that prior to commencing the shampooing process she informed Miss Dalrymple that the fumes might make her feel a little faint.

Now, from such a sequence of events, and also from the post-mortem notes, as recorded at the inquest, I firmly contend that Miss Dalrymple was dead before her body was laid on the floor, and that she could not have breathed any carbon tetrachloride fumes. My reasons are the following. The first ominous signs were noticed approximately "one to two minutes" after commencing the shampoo process, when about "four ounces only" of the solution had been poured on the hair. Also, I understand, the door of the cubicle was open at the time, and in which circumstance the greater part of the vapour would be blown on and out of this doorway. The sequence of events indicates a "quasi-acute" case of lymphatism and one in which both cardiac and respiratory functions must have ceased practically simultaneously, and it does this: 1. Because of the great rapidity with which the ominous signs succeeded one another. 2. Because sudden and extreme pallor was the first and most striking feature of the fatal termination and not cyanosis—which would have indicated that the respiratory centre was being affected either before or to a greater extent than the cardiac centre; and it is in the first-mentioned condition-i.e., when both cardiac and respiratory centres are seized suddenly and simultaneously or when the cardiac centre is either affected first or to a greater extent than the respiratory centre—that death is so very sudden. 3. Because a blue discolouration became evident the moment Miss Dalrymple's body was laid on the floor, consequently it supervened very quickly and became more noticeable in the face when in the recumbent posture. 4. Because the "blueness" was a dusky-leaden blueness and more noticeable at the back of the neck, possibly from hypostasis. 5. Because of the extremely marked degree of flaccidity that very suddenly and very rapidly manifested itself.

6. Because no audible or visible respiratory gasps were noticed. 7. Because Miss Dalrymple's sudden death is perfectly comparable with three other quasi-acute cases of my own observation -reported fully in THE LANCET and Journal of Mental Science - in which death was equally sudden, the exciting causes equally insignificant, and in which the necropsy disclosed pathological changes such as are consistent with lymphatism and lymphatism only.

The post-mortem facts, as recorded at the inquest, indicate the same: 1. Because rigor mortis was chiefly present in the lower extremities, suggesting a sudden death in which the muscles of the legs, which had probably been most exercised just before the fatality, were being chiefly affected. 2. Because there was a livid discolouration of the face and head, indicating sudden death, and probably the same lividity that was becoming evidenced even while on the floor at Messrs. Harrods' hair-dressing department. 3. Because the heart cavities were dilated and the muscle degenerated, also because the arteries of the heart were very narrow.

¹ Depositions say, "Hardly two minutes, I should think,"

indicating a well-marked or quasi-acute case of lymphatism, and one in which both respiratory and cardiac centres are usually affected suddenly and more or less synchronously, with the inevitable result, sudden death. 4. Because the kidneys were a little congested, to me another indication of a quasi-acute example of the status lymphaticus. 5. Because the lungs were congested—a point that I have commented on before in such cases of sudden death from lymphatism.

At the inquest no notes were recorded as to whether the glands in the mesentery were dark or pale pink in colour; whether they were uniformly large or uniformly small whether there was or was not any general enlargement of the smaller peripheral mesenteric glands; and whether some groups of glands were larger and paler than others. Also the condition of the miliary lymphatics in the stomach, cesophagus, and intestines was not recorded. All these points might possibly have thrown further light on the case. The cavities of the heart presumably did not contain any noticeable quantity of blood, since no mention is made that they did, and I consequently surmise that it is not improbable that its action ceased during systole, as it usually does in such cases. In THE LANCET of Dec. 26th, 1908, I drew attention to the fact that of deaths occurring while under general anæsthetics from the status lymphaticus the catastrophes always happened during light anæsthesia, either before reaching, or on recovery from, the third stage of narcosis. In some instances where chloroform has been administered for an hour or more during a protracted operation, although no untoward symptoms may have been present at any time during the whole of the administration, nevertheless, just as the patient is beginning to come round and the last few skin sutures are being inserted he may suddenly die.

From this, and also in consideration of the extremely trivial firing-off causes that may be sufficient to give rise to a fulminating termination resulting in sudden death, I argue that the effects of shock in such cases are probably of more importance than the effect of the narcotic. In Miss Dalrymple's case, shock, caused by cognisance of the fear that she might feel faint, subsequently reinforced by the shock of the cold lotion applied to her head, would be, at a coincidently critical period, quite a potent enough exciting cause of sudden death. In conclusion, I was sorry that both Miss Dalrymple's former medical attendant and the coroner's jury should have attributed this sad and unfortunate disaster to "Death from misadventure," when surely the true verdict should have been one of "Death from natural causes."

Since writing the above I have read with great interest the letter of Dr. Donald J. Munro published in THE LANCET of Nov. 13th (p. 1468), and I would here like to take the opportunity of endorsing many of his views. practical purposes the first point of paramount importance is the question of diagnosis, and in this connexion may I be allowed to suggest some modifications of Dr. Munro's restrictions of the term "status lymphaticus"? opinion the five following physical signs and symptoms are the most important and are arranged in order of merit. 1. Signs of a persistent thymus gland as evidenced by a lowering of the upper border of superficial cardiac dulness in the absence of emphysema of the lungs, or old tuberculous cavities at its bases, with or without fulness of the episternal notch, and not by a dulness to percussion behind the manubrium. This region may even be a little hyper-resonant, and if dulness is present it is probably due to some new growth, and not to a simple hyperplasia of the thymus gland. 2. An uniform prominence of all the papillæ of the tongue, especially the circumvallate papillæ, between which and the epiglottis posteriorly there is frequently present a great multiplication, hypertrophy, and hyperplasia of all the lymphatic nodules, giving rise to a very characteristic picture, many of these sessile nodules measuring about 1-8th to 3-16ths of an inch in diameter at their bases; the condition cannot be seen without the aid of forehead and laryngoscopic mirrors. 3. A symmetrical enlargement of the thyroid gland. 4. Distant and muffled heart sounds, with absence of the sharply defined click caused by closure of the valves, associated the sharply defined click caused by closure of the valves, associated the sharply defined click caused by closure of the valves, associated the sharply defined click caused by closure of the valves, associated the sharply defined click caused by closure of the valves, associated the sharply defined click caused by closure of the valves, associated the sharply defined click caused by closure of the valves, associated the sharply defined click caused by closure of the valves. ciated with a soft, weak, and ill-sustained pulse, and, as Dr. Munro states, often abnormally slow and inexcitable. 5. A greater or less amount of hyperplasia of any or all of the faucial, pharyngeal, and lingual tonsils, also of the uvula, and the presence of adenoid growths in either very small or

large quantities. Either or both the liver and spleen may, or may not, be enlarged, and to such a variable extent that no reliance can be placed on the absence of physical signs of enlargement, and very little indeed on the presence of the same. The pupils of the eyes also may appear rather dilated. The co-existence of 1 and 2 is pathognomonic of the disease.

Lastly, I cannot agree with Dr. Munro when he says, "No clinical observation has ever been so hopelessly mistaken as that which stated that pregnancy conferred immunity from the poisonous effects of chloroform." True, there are here more factors than one tending to produce an overdose of the vapour, but the anæsthetist is prepared for this. Despite the mechanical embarrassment to respiration, as Dr. Munro says, the heart is stronger than normal, and the increased carrying capacity of the red blood corpusele I would regard as a "virtue" rather than a "vice." This factor, coupled with the toxemia from over-metabolism, probably in large measure accounts for the reason that so little chloroform is necessary to produce and maintain an efficient and safe anæsthesia during parturition. Is it not sometimes advisable to artificially produce a toxemia by giving a hypodermic injection of morphine preparatory to the administration of chloroform? Probably if one had to maintain surgical anæsthesia or the third stage of narcosis during parturition it would not be as safe as it would be apart from the condition, but surely "light" anæsthesia is much safer at such a time than it is at any other.

I am, Sir, yours faithfully,
R. ERNEST HUMPHRY, M.R.C.S. Eng.,
L.R.C.P. Lond.

Northwood, Middlesex, Nov. 15th, 1909.

CIVILISATION AND THE CORSET.

To the Editor of THE LANCET.

SIR,-May I correct an impression which Mr. Heather Bigg conveys in his communication on the above subject? He seems to think that men in "sultry and atonic countries"—I wonder what he means by an atonic country?— "gird the loins" with a view of supporting nature's incompetent abdominal walls." Some years ago I unexpectedly met in Calcutta a very distinguished London surgeon, an old fellow-student, who was spending his summer holiday in going to India to personally see a thing of which he heard in connexion with native customs; if Mr. Bigg would follow that example he would see personally that "girding of the loins" has nothing whatever to do with artificial support. He need not go beyond Aden, where he will see the Arab camel-drivers coming in from the desert, among whom he will see magnificent specimens of activity. "Girding of the loins" really means girding of the loin cloth, which is wrapped round the body, passed through the legs, and tucked in at the waist, and is no more worn for the purpose of support than our trousers are so worn; nor, if it were conceivably the object, could it be obtained in any better degree than by our trousers. It is obvious that the cloth is liable to work loose, being only tucked in, and "girding of the loins" means readjusting it and tucking it in again, and the object corresponds to our object in wearing braces. Natives of India, whether fighting as uniformed Sepoys or in their native garb, Britishers, whether fighting or engaging in friendly contests, do not wear, and do not need, any artificial support. I do not wish to contend for or against the use of corsets, the women will settle that for themselves apart from contradictory statements and opinions of the profession, but I do wish to correct an impression which may mislead others in supposing that in a country like India—if Mr. Bigg calls that an atonic country, and a visit there will correct him on that point-men have to wear artificial support for their loins and abdomens. The impression might lead to the thought that it is necessary in this country, though not among those accustomed to, or knowing anything about, exercise. Fancy a Marathon runner running in an abdominal belt!

In conclusion, I may go one point further and say that which is demonstrable—namely, that where the natural muscular support of the loins and abdomen is deficient from want of tone, the best way of preventing recovery of tone is to provide artificial support, and in no cases is this so lamentably obvious as in the indiscriminate ordering of

supports for spinal cases, and I am constantly engaged in undoing the evil done in such cases, which evil admits of easy demonstration .- I am, Sir, yours faithfully

H. E. DEANE, Lieut Col., R.A.M.C. (retired). Weymouth-street, W., Nov. 29th, 1909.

To the Editor of THE LANCET.

SIR.—I read with great interest an article in THE LANCET of Nov. 13th, entitled, "Civilisation in Relation to the Abdominal Viscera," which opens up a subject of wide and ever-increasing importance. During the last year I have made a careful observation of a large number of cases varying in age from 15 to 50 years, having regard to those conditions which are said to result from chronic intestinal stasis, and I am bound to confess the existence of those conditions is confirmed by systematic examination. In hospital work we are able more accurately to estimate the severity and chronicity of constipation, and I should like very briefly to repeat some of the points which have been recorded in your columns and which have struck me most forcibly.

The worn and haggard appearance, the absence of muscular tone, the pigmentation of the skin in definite places, and the peculiar odour of auto-intoxication are most characteristic. Pigmentation is an early symptom and this staining may be very marked at a time when signs of degeneration are only just beginning to appear. Most constant and remarkable are the changes in the breasts, which at first feel lumpy and later show cystic degeneration.

There is a point in connexion with this which arrests attention, and that is that this cystic degeneration does not take place in married women who are having habitual intercourse. A striking illustration of this presented itself to me a short time ago. A married woman, who had one child, 15 years old, was admitted, having received a slight injury to the right breast a few days before. The patient, who had for many years been subject to chronic constipation, showed extensive cystic changes in both breasts. On inquiry it transpired that she had had no intercourse with her husband for 14 years.

Pregnancy has a beneficial effect on constipation; the enlargement of the uterus so alters the mechanics of the abdomen that the bowel can mere easily empty itself. Recently I had a typical instance of this. A woman, aged 39 years, was the mother of 14 children. She had been subject all her life to chronic constipation, except during her pregnancies when there was a daily evacuation and a consequent general improvement in health. The almost universal wasting that follows a long history of stasis is a prominent feature. Frequently these patients will say that up to the age of 19 or 20 they were stout, but that afterwards they gradually began to lose flesh until at the age of 35 to 40 they become very thin and wasted.

Enfeebled circulation with cold hands and cold feet is a source of great discomfort to the habitually constipated. Pain is always present, though it varies in position and severity and there are periodical remissions. These people are admitted into a hospital for various reasons. Loss of flesh, loss of appetite, indigestion, abdominal pain, vomiting, displacements of the uterus from loss of fat, sleeplessness, nervous depression are some of the numerous symptoms complained of. With painful monotony it is found that a long history of chronic constipation is given. They show some temporary improvement from treatment in bed, due in a slight measure to a daily purging, but chiefly to the assumption of the recumbent posture. It is surely not difficult to believe that a system whose resisting power is so lowered by auto-intoxication becomes an easy prey to the tubercle bacillus and other organisms.

These are some of the effects briefly enumerated which cannot fail to be noticed on methodical examination.

I am, Sir, yours faithfully,

Lewisham, Nov. 18th, 1909.

H. M. M. WOODWARD.

THE JUBILEE OF THE DENTAL CHARTER To the Editor of THE LANCET.

SIR, -The dental surgeons have shown themselves desirous of commemorating the Jubilee of their Charter, and the Royal College of Surgeons of England, as the first examining body to grant degrees in dental surgery, has endeavoured to show its interest in this branch of the profession, first, by accepting the trust of the Odontological Museum, which is

now accommodated in a room adjacent to the Hunterian collection; and, secondly, by entertaining the leading members of the profession at a dinner within the precincts of the College. I would venture to suggest that this movement might well be directed towards a more permanent memorial of the Jubilee of the Dental Charter by establishing a research scholarship and demonstratorship in connexion with the Dental Museum. There are already two small endowed prizes, the Tomes and Cartwright prizes, administered by the College, the one awarded every third and the other every fifth year; but the dental profession is deserving of something of a much wider scope than these for the stimulation of research and for the higher teaching of its scientific branches. My own view favours a far more ambitious scheme than anything in the form of a mere prize, whether awarded after examination or conferred in recognition of original work completed. I would ask for the modest sum of £10,000 to endow a research and teaching demonstratorship in connection with the Dental Museum. In this way not only would a scientific worker be secured, but he would by his demonstrations attract the students from the various dental hospitals to study in the Dental Museum. Such a sum could, I am sure, be easily collected from among the dental surgeons alone; but if they were to impress upon their patients the necessity of endowing dental research there need be no hesitation in raising the sum I have suggested to £50,000, whereby not only research and teaching demonstratorships might be established, but travelling scholarships might be founded which would be of great advantage in keeping English dentistry in touch with that of foreign countries.

It is some 25 years ago since I first began to advocate the bringing of the dental surgeons back within the pale of the profession and giving them the same opportunities as ophthalmic, aural, and other specialists. One could scarcely have anticipated so encouraging a development as has occurred within so short a period. The dental surgeons have not been slow of late to seize the occasions for better recognition, and by placing the Odontological Society under the ægis of the Royal Society of Medicine, and by handing over their superb museum to the care of the Royal College of Surgeons they have shown their desire to be associated with the general body of the medical profession. Now I think the time has come for the further development of the scientific side of the branch, in which direction several members have already gained great eminence.

Should my suggestion find favour with the dental section

of our profession, I should be pleased to cooperate with any interested in this project; but it must be distinctly understood that I write quite unofficially, though I have little doubt that the Council of the Royal College of Surgeons would give its consent to the administration of such a research demonstratorship as that proposed if the money

were forthcoming for its endowment.

I am, Sir, yours faithfully,

London, W., Nov. 27th, 1909.

R. CLEMENT LUCAS.

THE TREATMENT OF MORPHINISM.

To the Editor of THE LANCET.

SIR,-I have been much interested in the letters of Dr. C. J. Douglas and Dr. Oscar Jennings which have appeared in your columns under the above heading. The subject is in reality much larger than the heading might lead one to infer, for the treatment of morphinism is but a chapter in the volume on the treatment of habit, and accordingly the question raised in respect of one drug—the proper method of treatment of its abuse—is of fundamental importance and applicable in the main to all forms of drug abuse, if not to every form of acquired evil custom.

Dr. Douglas suppresses the habit, breaks its custom, by the help of hypnotic remedies; for him "sleep solves the problem of the painless withdrawal of morphine" when the patient "awakes the painful period is passed and all desire for morphine is gone.

Dr. Oscar Jennings also suppresses the habit, breaks its custom, but by the help of the patient's own good will, in arduous operation; his method stepping in to reinforce and encourage the operation of the will during the withdrawal of the drug, and, at the same time, to lessen the arduousness of

¹ THE LANCET, Oct. 2nd, 1909.

the will effort by various means which mitigate and make bearable the bodily sufferings.

The habit is thus suppressed in either case—Which is the better method? Treatment, the best treatment, is that which secures its end, cito, tuto, et juounde, and if we use these criteria we must allow that the former method excels in the oito and picunde; the patient is rid of his habit more quickly and more pleasantly, one should say less unpleasantly, for he sleeps it off. But how stands it as to the tuto? Which is the better man? Which will confront the future more safely—he who has worked out his own deliverance, helped. it is true, but taking his share of the pains and penalties of withdrawal, or he for whom all this was done whilst he slept . Surely there can be no question as to which of the two stands more securely? And does not the *tuto* outweigh by far the *cito* and the *jucunde?* From Dr. Douglas's letter of Nov. 27th we should conclude that the will is best conserved by lying dormant, which conclusion would present us with a new law of conservation and of growth!

Surely our task is to secure the conscious cooperation of the patient in his own cure, and to do this by so apportioning the magnitude of the task to the quantity of will-power available that it, the will, shall be able to operate. this apportionment there will be ample scope for mitigants of all kinds, including drug sedatives, and this Dr. Jennings's method fully recognises. What says Hippocrates in his opening aphorism? "Oportet autem non modo seipsum exhibere que oportet facientem, sed ctiam aegrum et praesentes et externa "---which injunction we take to mean that it is necessary, not only that the physician shall play his part in the cure, but further that he shall make to cooperate the patient, and the bystanders, and the external I am, Sir, yours faithfully, surroundings.

HARRINGTON SAINSBURY.

Wimpole-street, W., Nov. 29th, 1909.

To the Editor of THE LANCET.

SIR,—In his answer to my criticism Dr. C. J. Douglas has entirely misapprehended my views. He is quite mistaken in supposing my point to be that the will is better cultivated by a painful than by a painless cure, and in taking me to be the advocate of "long-drawn-out sufferings" in what he calls the painful withdrawal period. This is exactly the reverse of what I have always maintained, as I hold that there should not be a painful period at all and that renunciation should be effected without restraint, chemical or otherwise, because without any discomfort beyond what the patient is cheerfully willing to bear. In a morphia weaning there may be two varieties of distress: (a) craving proper, which really is unbearable but which is also quite preventable; and (b) different kinds of psycho-neurotic irritability, caused chiefly by want of self-restraint and aggravated tenfold by a wrong mentality. The first should be treated by the prevention of the factors of craving in their inception or their relief by suitable therapeutic measures. The importance of the second will be in inverse ratio to the patient's resolution and docility, and his reasonable confidence in the certainty of the ultimate result, all of which are, I think, lessened by a plan which minimises the necessity for self-mastery.

I quite agree with Dr. Douglas that weakness of mind and body may be caused by the prolonged wretchedness of a badly managed wearing. Nothing, indeed, can be more demoralising, but I have frequently pointed out how this can be prevented. The patient should, however, be led to control, rather than indulge, the morbid craving for relief by medicines, for it is, I believe, a mistake to suppose that the faculties of mind and body are always strengthened by such

The conquest of pain is undoubtedly one of the glories of modern medicine, but inasmuch as suffering in psychoneurotics depends greatly on the mental attitude its suppression by drugs exclusively cannot but encourage exaggerated reliance on drugs and stimulants in moments of stress and difficulty. This is dangerous teaching. It is, I think (if the object in view is permanent recovery, and not merely temporary suppression), better to re-educate a drugaddict up to a healthier ideal, and to prove to him by enabling him to do without them that for the cure of drug disease further drugging is not indispensable.

I am, Sir, yours faithfully,

Nov. 29th, 1909. . . OSCAR JENNINGS.

THE INFLUENCE OF DIET ON THE THYROID GLAND.

To the Editor of THE LANCET.

SIR,-If I am not trespassing too much on your columns perhaps you will allow me once more to write on this subject in reply to Dr. Forsyth's letter in your issue of Nov. 27th. In his letter Dr. Forsyth very definitely suggests to your readers that a whole host of investigators have made a special study of the direct influence of diet on the thyroid gland and that none of them have found the changes I have described. This statement is hardly in accordance with fact; on the contrary, it is so inaccurate and misleading that one must conclude that it was made unwittingly. I think I am right in saying that since I first drew attention to this subject in 1904, the only investigator who has published a lengthy series of observations is Dr. Forsyth himself. When he published his results in your columns in 1907 it appeared to me that in each of the directions in which he prosecuted his study he had overlooked an important fallacy, and that therefore the conclusions which he drew might be erroneous. I am now satisfied that such is the case. In the course of the past two years I have carried out in Professor Schiffer's laboratory in the University of Edinburgh a further investigation on this subject on an even larger scale than formerly, and the results of this amply confirm my earlier investigations. When the results of the investigation are published, which I hope will be shortly, I will deal in detail with the fallacies above referred to. I will also refer to the interesting results recorded by Dr. Edmunds. And if Dr. Forsyth will now justify his statement about "a whole host of investigators" I will look forward to incorporating in my paper a full reference to the results recorded by each I am, Sir, yours faithfully, observer. CHALMERS WATSON. Edinburgh, Nov. 27th, 1909.

THE INFLUENCE OF MIND AS A THERAUPEUTIC AGENT.

To the Editor of THE LANCET.

SIR,—The position of Dr. Morison on this subject does not seem quite clear. In the first part of his letter he says that if a patient can be "restored to greater equanimity and good placing the hand on the pit of the stomach, &c.), no one could object. Later be could be a stomach, &c. could object. Later he speaks of hypnotism as tionable," and inquires if it can be brought about without change in the mental organism"? Assuredly and inquires if it can be brought about not. The experiments of Liébeault seem to demonstrate that a change does take place, and that this change is in the direction of diminished self-control, diminished will-power, and diminished reasoning powers, and thus in the direction of insanity. On the first attempt to hypnotise a patient (and I believe this is the experience of all hypnotisers) there is usually a resistance on his part which it takes some five or ten minutes to overcome. On the next and subsequent occasions this resisting power has ceased to exist, and the patient succumbs at once to the hypnotic influence. Some change has certainly taken place in the mental organism, a change indicating an enfeebled will, and tending, if not yet absolutely amounting to, a condition of induced insanity. Rational persuasion is one thing and hypnotic suggestion is another, but when the latter takes the form of inducing the patient to believe what sound reason tells him to be impossible, as that pain is non-existent, or that paraffin is a potation to be desired, it is no longer a case of reason or argument but simply one of induced insanity. Such is hypnotic suggestion. It is "the acceptance of a proposition in the absence of logically adequate grounds" through the mental influence of another. This is its essential feature, and why such action is not a criminal offence it passes the wit of man to conceive. If it is criminal to destroy human life, it must be tenfold more to destroy reason, for I have never yet seen a human being who would not rather part with life than reason. If this fact were fully recognised hypnotism would surely be condemned by all rightthinking persons both in the medical profession and out of it. It is the more execrable in that it is only the feeble minded who are subject to its influence.

These are surely no less deserving of our protection than the feeble in body. To take advantage of the feebleness of intellect of one already on the borderland of insanity to annihilate by hypnotic suggestion the little remnant of reason and will-power that remains to him is equivalent to destroying a feeble, defenceless, or injured life. The gift of reason and free-will is our most cherished possession, and I maintain that we have no more right to deprive a human being of this gift for the sake of supposed ulterior advantages than we have to destroy human life for the supposed benefit of the human race.—I am, Sir, yours faithfully,

Royal Avenue, S.W., Nov. 22nd, 1909. J. FOSTER PALMER.

A STATE DEGREE IN MEDICINE: ONE PORTAL TO THE PROFESSION.

To the Editor of THE LANCET.

SIR,—In your report of the speeches at the Lord Mayor's Day dinner at the Apothecaries' Hall you say the "Senier Warden advocated the establishment of a State University of Medicine as the single method of entering the profession, but Sir Douglas Powell pointed out that a one-faculty university was a contradiction of terms." On this point I would suggest that if a charter were granted to a State university with teaching powers (where advantageous) it certainly would not remain long with one faculty.

I cannot but think that the plan put forward by the two Royal Colleges has very little chance of success. They can scarcely hope for the assistance of either the Faculty or the Senate of the London University and must therefore rely upon the Royal Commission recommending Parliament to compel the Senate to make such alterations in the University examinations as may coincide with the views of the authorities of the two Royal Colleges. The only alternative suggested by the Colleges is the possibility of combining with some other existing university. I cannot look upon this alternative as one to be desired and naturally think that my suggestion, with perhaps some slight modification, would be a much preferable alternative and a more feasible scheme to be put before the Royal Commission.

I am, Sir, yours faithfully,

Leyfields Wood, Ashampstead, Nov. 24th, 1909. A. T. NORTON.

ON RADIUM IN THE TREATMENT OF CANCER.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Nov. 13th Mr. Butlin gives some cases of cancer treated by radium, in which the condition of the blood is not alluded to. It would have been of the greatest interest if we could have had a record of the condition of both the red and white cells before treatment, while local improvement was going on, and afterwards when the ulcerations had broken out afresh. The cases are not of the kind in which one would expect very marked blood change, but it might have been sufficiently noticeable to make it appear at least possible that, had injections of iron and arsenic been given at the same time, results might have been better.

When we know the effect on the blood in cases of cancer treated by X rays or radium, and if it turn out, as seems likely, that the improvement is entirely local, the blood not being materially affected, we may by judicious combination of X rays or radium and injections of iron and arsenic cure a greater number of cases than is at present possible by means of one or other line of treatment. Personally, I should be very grateful to anyone who can supply me with any information as to the result on the blood in cases of cancer treated by radjum or X rays.—I am, Sir, yours faithfully,

London, W., Nov. 25th, 1909.

SKENE KEITH.

THE TREATMENT OF CHRONIC ULCER OF THE LEG.

To the Editor of THE LANCET.

SIR,—Among the various treatments suggested for this condition I see no mention of the simplest and, in my experience, by far the most effective—i.e., by exposure to the air. For some years I have treated all my cases in this way, and have obtained far quicker and more lasting healing than by any

other method. In winter the rest of the limb must be kept warm and in summer the wound must be protected from flies by a cradle covered with gauze. I have also found the same treatment most effective for burns of limited area and lacerated wounds which refuse to heal.

I am, Sir, yours faithfully,

Uckfield, Sussex, Nov. 22nd, 1909.

E. H. SWEET.

MALARIAL FEVERS IN INDIA.

REPORT ON THE CONFERENCE APPOINTED BY THE GOVERNMENT OF INDIA.

(FROM A SPECIAL CORRESPONDENT.)

(Concluded from p. 1549.)

Conclusions and Recommendations.

THE conference concluded its sittings at Simla on Monday, Oct. 18th. The conclusions and recommendations have been drawn up under the following main headings:

1. Scientific investigation. 2. The agency by which investigations should be made. 3. Practical measures: (a) extirpation of mosquitoes; (b) quinine treatment and prophylaxis;

(c) education; and (d) finance.

The following is a summary of the details under the first heading (scientific investigations). It is recommended that arrangements should be made for the immediate systematic investigation of (1) distribution of malaria; (2) (a) its epidemiology and endemiology, including relation to meteorological and physiographical conditions, and (b) the life history of malaria-bearing mosquitoes; and (3) the physiological and therapeutical action of quinine and other remedies for malaria. It is recommended that vital statistics should in future be compiled by smaller units tham at present to prevent the true distribution of malaria being obscured, and that tests of registration work should be introduced in selected areas conducted by a special staff, carefully supervised. Special attention should be directed to non-endemic areas to ascertain the reasons for such immunity.

As to the investigation agency (2), it is recommended that a local organisation should be established in each province to work in consultation with the central scientific committee to be appointed by the Government of India to direct and coördinate investigations. An annual meeting of the central committee and a delegate from each organisation to be held at a convenient centre to review the work done and prepare

a programme for future work.

The practical measures (3) are divided into four sections. The first relates to the extirpation of the anopheles mosquitoes, as to which continuous investigations are recom-mended to ascertain how this can best be done at a cost not Among the measures for the extirpation of prohibitive. mosquitoes the conference make recommendations as to (1) drainage, including the restriction of wet cultivation in the vicinity of towns, if likely to breed mosquitoes;
(2) oiling with petroleum of small collections of water which contain the larvæ of anopheles mosquitoes and cannot be filled up; and (3) introduction of fish into collections of water if inquiry shows that this will check the breeding of anopheles mosquitoes. The second subsection adopts the conclusion of a subcommittee formed of members of the conference which recommended that quinine should be given in the form of sulphate or hydrochloride for adults and in a palatable form for children. Quinine should be available in tablets of five grains each, which is the proper prophylactic dose for adults. The agency for quinine distribution should, in addition to postmasters, include all grades of officials. Special efforts should be made to induce private vendors to engage in the business and a liberal commission allowed. The educated classes should be invited to organise means for spreading a knowledge of quinine among the lower classes. As further measures to disseminate knowledge, moveable camps, itinerant dispensaries, leaflets ard advertisements, especially in the vernacular press, and instruction in all grades of schools are proposed. The free distribution of quinine as a prophylactic is recommended only in cases of severe epidemics (with exceptions left to the discretion of local governments) and in the case of school children in malarial tracts during the malaria season.

On the suggestion of Sir H. Risley it is proposed that a committee of officials and non-officials to be chosen by

elected members of the new councils should be formed to spread knowledge regarding malaria and proposed preventive measures among the people. Under (e) (education) it is recommended that text-books for schools should include lessons in malaria and hygiene. Divisional and district committees and local societies should be organised similar to the league started in the Gurdaspur district of the Punjab. The sanitary department should be organised with reference to the suppression of malaria as well as to general sanitation. As to financial considerations (d) each local government is invited to make an annual assignment for malaria investigation and preventive measures, which have also a strong claim on all increases and surpluses of revenue. Municipalities and local boards are also urged to set apart funds for the prevention of malaria.

TOWN PLANNING AND THE SANITARY HISTORY OF DWELLINGS.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

PROPOSED BRITISH ADAPTATION OF THE PARIS "CASIER SANITAIRE," OR HEALTH RECORD OF EVERY DWELLING.

—THE RESULTS OF 11 YEARS' EXPERIENCE.—TUBER-CULOUS HOUSES AND CANCER HOUSES.

ONE of the clauses in the Town Planning Bill provides as follows:-

It shall be the duty of every local authority within the meaning of Part II. of the principal Act to cause to be made from time to time inspection of their district, with a view to ascertain whether any dwelling house therein is in a state so dangerous or injurious to health as to be unfit for human habitation, and for that purpose it shall be the duty of the local authority and of every officer of the local authority to comply with such regulations and to keep such records as may be prescribed by the Board.

This is in imitation or adaptation of what is known as the Casier Sanitaire des Maisons, which constitutes one of the most thorough and useful methods of sanitary control established in Paris. In 1894 the first attempts to get something like a sanitary record of houses in Paris had so far advanced that the results commenced to be recorded. On August 13th, 1898, p. 424, we published a lengthy account of the endeavour made by the Bordeaux authorities to imitate the example of Paris. By that time a full sanitary history had been drawn up of 2000 out of the 36,000 houses that then constituted the town of Bordeaux. How the investigations were made, the results recorded and rendered available for prompt reference, we described at the time. To-day in regard to Paris not only can the system be explained but it has been in full working order for a sufficient number of years to be able to form some idea of its usefulness. It is no longer the history of insanitary districts but of the entire capital, and the history of the most healthy quarters is only second in importance to that of the worst slums. But for the record kept concerning the best property we should have no standard by which to judge the extent of the evil wrought by the worst property. According to the census taken in 1901 there were in Paris 77,149 houses. To day the Bureau Administratif des Services d'Hygiene de la Ville de Paris possesses, if set down in round figures, the sanitary history of 80,000 houses, showing that all the older and nearly all the recently constructed dwellings have been duly inspected and their history noted down.

How is all this done? The service as established in Paris now works with the greatest ease, promptitude, and regularity. The sanitary history of every house is written up to date, can be found in a moment, and is never more than two days old. When a death is recorded, a contagious disease reported, a disinfection ordered, the notification of this fact, in passing from one service to another, takes 24 hours to reach the bureau of the casier sanitaire. Another 24 hours may be allowed as the utmost limit of time before the fact is entered into the casier of the house in question. There are as many casiers as there are houses. A casier consists of a stiff piece of imitation parchment which serves as the wrapper of a small portfolio. It is white, and on the ontside is written the name of the street, number of the house and of the arrondissement, and name of the quartier or sub-district. On the inner side of this wrapper, painted red, is a small ground plan of the house. Within are kept five different-coloured printed forms with blank spaces for the details to be written in, and these are identical for all

the houses. The first, a white sheet, contains a general description of the house. There are the measurementsnamely, the length of the facade, the depth and the superficial area. We are then told where the entrance doors are situated and whether the house is built in one solid block or has wings. This includes the very important question of inner courts, their number and superficial measurements, and how they are paved. Now a line is drawn across the sheet, and the second division thus made deals with the means provided for getting rid of the slop or waste water. The questions put relate to the number and situation of the sinks, whether they give on to open or covered drains, and where is the ultimate outfall. A third division asks for details as to the soil pipes and which of the prevailing systems is applied: - the cesspool, the moveable pail or tub, the dividing apparatus that retains the solids and lets the liquids flow into the sewer, or the more recent tout à l'égout system allowing everything to drain direct into the sewer. After that it is necessary to state how many closets there are, whether private or shared by different tenants, and how many soil pipes. The fourth division is for all that relates to the water-supply. The last and fifth division gives the number of rooms on each floor, on which side their windows are placed, whether looking out on to the street or a court. and whether there are any shops or workshops or cellars. Finally, the number of inhabitants and the date of the last inspection are noted down.

The next printed form is on yellow paper, the quarantine colour, and is entitled Disinfection. It is subdivided into a number of vertical columns. The first of these is broad enough to inscribe clates. Then there are 10 columns, each with the initial letter of a transmissible disease. These are typhoid, measles, scarlet fever, diphtheria, small-pox, whooping-cough, cholera, tuberculosis, erysipelas and puerperal cough, cholera, tuberculosis, erysipelas and puerperal fever. Then comes a dividing line and another series of 10 columns under the general heading of "other diseases." are cancer, pneumonia, dysentery, and various diseases for which disinfection, though sometimes desirable, is not generally practised. Whenever a disinfection is carried out the date and cause are entered on this yellow sheet. Thus it is possible to tell at a glance how often it has been thought necessary to disinfect in the dwelling and for what diseases. The next sheet of paper is of a light green colour, and is divided into similar vertical columns, and with the same rapid facility the deaths, the date, and cause of those deaths are seen. The fourth paper is light blue, and has for title "Unwholesome Dwellings." The first line gives the date when notification was received that the house was believed to be in an insanitary or unwholesome condition. Then comes the date of the report on the dwelling drawn up after investigation by the "Commission on Insalubrious Dwellings," and the third line gives the date of the prefectorial ordinance issued in consequence of this report. After this follows a description of the alterations and improvements that have been ordered by the prefect. Lower down is space for the list of fines or other sentences pronounced, if any, against the owner or other person responsible for carrying out the improvements in case of failure to obey the instructions. Finally, there is a place to inscribe the date when the works ordered were satisfactorily terminated. Thus on this light blue sheet we have the record of all sanitary works, alterations, or repairs. Finally, there is a dark blue sheet printed on both sides and containing a large number of questions which have to be answered when the inquiry is held as to the sanitary condition of the house.

Such investigations have now been made for every house. though, of course, at different dates, and conditions may alter after the inspections. On the other hand, the inspections can be renewed from time to time, and the inspectors now know from the casier sanitaire the general character and the past history of the house they may be called upon to re-inspect. All these documents are kept in a surprisingly small space. A room of moderate size suffices to hold them. It is divided up in rows of shelves, like book-cases. Instead of books there are cardboard portfolios of the same size but varying thickness, one portfolio for each street, or section of a street if it be a very lengthy thoroughfare, and inside, in numerical order, are the casiers of each separate house. The portfolios are placed in alphabetical order. Though there are now 80,000 separate casiers corresponding to each of the 80,000 houses of Paris, it does not take longer to pick out any one particular casier than it does to find a word in a dictionary. Every day all the deaths that occur are at once added to the history of the houses in which they take place; so also with regard to the disinfections practised and all the other details mentioned above. A few clerks are employed to do this work punctually and promptly. But not only is the history of each house kept well up to date, methods have now been introduced of analysing the results of the immense amount of information received. Thus we have not only the sanitary history of each individual house but also of each street or group of dwellings. In this way the healthy and unhealthy quarters are marked out with great accuracy; and this not merely in the general sense but also in respect to various diseases taken by themselves.

Before, however, dealing with these general results, the question naturally arises as to how far the caster sanitaire can be of use to any individual member of the community. Obviously anyone about to take up his abode in a house, to lease or purchase a part or the whole of a house, would very much like to know whether the premises were noted favourably or unfavourably in the municipal records. On the other hand, if all the information now collected was made public private interests would be compromised. Doubtless many speculators in slum property richly deserve the public pillory. Nevertheless, if everybody could look into the casier sanitaire of any house there are persons who would make malicious use of information thus obtained, to say nothing of giving unnecessary trouble to the employees in charge of the casiers. Thus as a rule the only person who can ask to see the *casier* of a house is the owner or person legally responsible for the property. Therefore an incoming tenant has not the right to go to the Hôtel de Ville and ask to see the casier santaire of the house in which he proposes to live. On the other hand, before signing a lease or purchase deeds a condition can be made that the owner shall allow the person with whom he is negotiating to examine the casier sanitaire of the property in question. It would be a very useful help to the progress of sanitary reform if all tenants insisted on seeing the casier sanitaire before they signed leases or purchased property. But it is to be feared that this could not be done just where it is most needed—that is, in regard to the poorest property where many of the tenants are only weekly tenants.

The result of the house-to-house inspection, rendered necessary to fill in the casier sanitaire of every dwelling, has been the execution of an enormous amount of sanitary work. During five years ending on Dec. 31st, 1908, no less than 19,400 houses visited were noted as requiring more or less important repairs or alterations. As a rule the house-owners were well disposed and willing to carry out the instructions given them. Only in 693 cases was it necessary to commence legal proceedings, and of these but 148 were brought before the Council of the Prefecture. It is noted that the recalcitrant proprietors are among the most wealthy owners of extensive property; the smaller owners are much more ready to carry out instructions though involving considerable expenditure. These alterations and improvements, however, only affect matters of detail-a better soil-pipe, a ventilator here, an extra window there—whereas what, in many cases, is needed is the total demolition of dwellings that are so built that they can never be healthy. But the collection of information, in so complete and systematic a manner, enables the authorities to point out at once which are the worst spots. Further, and to supplement the information, the Paris Municipal Council in 1908 decided that anti-tuberculosis dispensaries, and other institutions of this sort, should only receive subventions if they supplied in a uniform manner very detailed information concerning their patients. Thus the connexion between certain quarters and certain occupations and the prevalence of tuberculosis is being clearly established. There are also figures showing the comparative susceptibility of the Parisborn population and those who have migrated to the capital.

During a period of 11 years (1894-1905) there have been 138,766 deaths due to transmissible diseases in 50,394 houses. Of these deaths 101,496 were caused by tuberculosis and they occurred in 39,477 houses. Analysing these figures, the authorities note that there were 23,124 houses where the only deaths from transmissible diseases were due to tuberculosis. The 39,477 houses in which 101,496 deaths from tuberculosis have occurred are divided into three classes or categories. In the first

class are the houses where less than five deaths from tuberculosis have been recorded during the 11 years. There are 34,214 such houses, and the total of deaths from tuberculosis occurring in them was 63,487, or an average of a little less than 2 deaths per house in 11 years. The second class are houses where there have been, from this cause and during this period, at least 5 deaths and not more than 9 deaths. There are 4443 such houses and 26,509 deaths occurred in them. The third class are the houses where the number of deaths amounted to 10 or more. There are 820 such dwellings, and in them 11,500 deaths from tuberculosis took place during the 11 years. Taking the last figure, it will be seen that 10 per cent. of the total number of deaths from tuberculosis occurred in 820 houses—that is, in the forty-eighth part of the houses affected, and the hundredth part of the total number of houses in Paris. But a house is a vague term, and it is above all necessary to know how many people dwell in these houses. official reports drawn up by the Department of the Municipal Administration, which has the management of the caster sanitaire, give us this information. M. P. Juillerat, the chief of this department, presents each year an admirably prepared report to the Prefect of the Seine.

The second and third class of houses, as defined above, comprise together 5263 houses, and they had a total population of 426,676 inhabitants. Of this number, 38,009 died from tuberculosis during the 11 years, which is equal to 89.31 per 1000, or an average annual mortality of 8.119 per 1000. The average annual mortality from tuberculosis in Paris, as a whole, is very high. During the 11 years in question it amounted to an annual average of 4.95 per 1000 of the population. But it will be seen that in the second and third categories of houses just mentioned it was much above the average. If, however, we take the figures for the 820 houses of the third and worst class the discrepancy is still greater. These houses had 106,300 inhabitants and 11,500 of them died from tuberculosis during the 11 years, which is equal to 108.181 per 1000 in the 11 years, or 9.834 per 1000 per annum. The houses of the second class with average annual mortality from tuberculosis of 7.52 per 1000 have an average population of 71 inhabitants in each house; while the houses of the third class, with average annual mortality of 9 834 per 1000, have an average population of 130 persons per house. There is a further significant distinction to be made. Of the 820 houses of the third class, 195 consist of cheap furnished rooms, while the rest are let to people who possess their own furniture. These latter 625 houses had 92,670 inhabitants, and the annual average death-rate from tuberculosis was 8.44 per 1000. The remaining 195 houses, consisting of cheap hotels or furnished rooms, had 13,630 inhabitants, and during the 11 years their average annual death-rate from tuberculosis amounted to 19.20 per 1000! This is indeed an appalling figure, all the more so as it is quite evident that it results from the sort of dwelling in which these unfortunate people live and die prematurely. These tuberculous houses, as they may well be called, are rarely isolated, but stand in groups in narrow streets and are lofty, with but very small backyards. Equally instructive is the calculation made in the opposite sense. Paris, with a total population of 2,660,559, had, as already mentioned, an average mortality from tuberculosis during the 11 years of 4.95 per 1000. But, if we deduct from this total population the 426,676 inhabitants of the two worst classes of dwellings, the death-rate among the remaining 2,233,882 would only amount to 2.56 per 1000 per annum.

It may be said, however, that the moral to be derived from these figures is already well known, though it has rarely been illustrated on so large a scale. But the casier sanitaire supplies the means of making other sorts of investigations on problems that have not yet been elucidated. Thus, for instance, a suspicion has gained ground that there are such things as cancer houses. Now, in Paris, this can be tested on a sufficiently large scale to be able to arrive at some conclusion. With 80,000 houses and a population of more than two and a half millions under close and daily observation, some general deductions should be possible. A special method of registering has now been established in regard to cancer. a death occurs from this cause, it is not only entered in the casier sanitairs of the house where it has taken place, but also on a stiff card similar to those used for library catalogues. These cards are white and are placed in the usual long, narrow drawer; but when it happens that a second

death from cancer takes place in the same house then a red card is substituted for the white one. Thus the prevalence of red shows the proportion of houses where more than one death from cancer has been notified. This service was commenced in August, 1906, and up to Dec. 31st, 1908, the deaths from cancer registered in this manner amounted to 6980. One death from cancer took place in each of 5786 houses, and of these 922 houses were qualified as tuberculous houses—that is to say, they belonged to the second or the third class, according to the classification described above. Two deaths from cancer are noted in 442 houses, of which 142 houses are qualified as tuberculous houses. Three deaths from cancer are noted in 51 houses, of which 25 are tuberculous houses, and 4 cancer deaths in 4 tuberculous houses, one of them being a convent. Other deaths from cancer occurring in convents and asylums may be set aside, as also 84 deaths in hospitals. They would only bear on the housing problem if the previous history of the patients was forthcoming. The point worth noticing which these records are already able to establish is that one-fifth of the deaths from cancer have taken place in houses that possess a sinister reputation for the prevalence of tuberculosis. Then, when there is more than one death from cancer in a set of houses, the proportion of tuberculous houses increased. Where there is but one death from cancer the proportion of tuberculous houses is one-sixth. Where there are two deaths from cancer the proportion of tuberculous houses is one-fourth. Where there are three deaths from cancer then half the houses are tuberculous. Finally, with four deaths from cancer in one house then all the houses are tuberculous. It would seem also that the confined life in convents and asylums for the aged favours the growth of cancer. Putting these institutions aside, and returning to ordinary dwelling-houses, during the course of two and a half years it has been found that among the houses where a death from cancer has taken place 10 per cent. of these houses have had more than one death to record from this disease. This, it may be said, is not yet conclusive; but when these observations have extended over several more years it seems from what we already see that some very useful deductions will be obtained.

The collection and verification of such figures is one of the services that a systematic record of the sanitary history of dwellings has rendered, and they justify an attempt on our part to follow and improve upon the example given by the sanitary administrative services of the city of Paris.

BRISTOL AND THE WESTERN COUNTIES. (From our own Correspondent.)

New University Buildings.

AT a recent meeting the University Council authorised the and of chemistry. The work was begun within three days and is now in progress. The site is a part of the grounds of the Blind Asylum, the purchase of which has been alluded to in previous letters, and the new buildings will be continuous with those already standing. They will cost £35,000, exclusive of furnishing, and will be so arranged as to permit of further extension should the occasion arise. One entrance from Woodland-road is provided for in the plans, and the University buildings will thus gain a double frontage. The plans for both departments have been most carefully prepared. Professor Stanley Kent has visited many of the corresponding continental institutions, and has, in company with the architect, Mr. G. H. Oatley, inspected the majority of the physiological departments of the United Kingdom. The chemical buildings will also constitute a very complete and up-to-date equipment, and Professor Francis is to be congratulated on so well deserved an outcome of his labours on behalf of his department. In the buildings of science, as well as of medicine, space is urgently needed, and this pressure will be greatly relieved by the migration of physiology and chemistry to their new quarters.

A Silver Mace.

The Council of the University has gratefully accepted the offer of Mr. Stanley H. Badock, late Sheriff of Bristol, to present a silver mace to the University.

The Medical School Dinner.

Until this year it has been the custom to open the winter Animals."

session of the Bristol Medical School with a prize-giving ceremony in the afternoon followed by the dinner in the evening. This year, however, the prize distribution was dispensed with and the dinner was postponed from the beginning of the session to a later date. On Nov. 23rd over 100 past and present students, with the teaching staff, sat down to dinner at the Royal Hotel. The King's health was proposed by the President, Mr. C. K. C. Herapath, an old Bristol student and a practitioner of high repute in the city. The Vice-Chancellor, Sir Isambard Owen, in proposing the health of past and present students, expressed his delight at seeing so large a muster, and painted for his hearers a picture of the University of Bristol as he hopes it may be in the future, in words which suitably clothed large and inspiring ideas. Sir Isambard Owen laid special stress upon the fact that this is the day of opportunity for the provincial medical schools, a subject upon which his experience entitles him to speak with unique authority. His health was proposed in terms of "Welcome to Bristol" by Dr. D. S. Davies. The toast of "The Medical School and other Departments of the University" was entrusted to Dr. T. M. Carter, and that of "The President" to Mr. Charles Corfield. Some excellent songs helped to add gaiety to a very cheerful and successful occasion, and everyone present must have felt that the "arrival" of the University has given a new momentum to the progress of medical education in Bristol.

Phthisis in Bristol.

The inadequacy of the means at present in use in Bristol for the prevention of consumption and the treatment of consumptives has recently been forcibly stated by more than one member of the health committee of the municipal council. The chairman, Mr. Colston Wintle, at a meeting held on Nov. 16th, said that the 20 beds which are provided for by the city in the sanatorium at Winsley are quite inadequate even for the very carefully selected cases which are considered suitable for admission; while, in addition to those people who are in a condition to benefit by sanatorium treatment, there is a very much larger class of more or less advanced cases for whom no provision whatever exists, although these are the very people who inevitably act as disseminators of the disease. For such people Mr. Wintle would like to see some kind of colony system established. At the same meeting Mr. E. M. Dyer spoke of the necessity for compulsory notification as the basis of a successful campaign against phthisis.

The Bath Sewage Disposal Scheme.

The Bath Corporation recently applied to the Local Government Board for sanction to borrow £213,000 for sewage disposal works. The Board has now written stating that it approves the main principles of the scheme, but it will require some other additions to be carried out, including increased pumping plant.

Proposed New Sanitary District for Devonshire.

At the last meeting of the Axminster (Devon) rural district council a communication was read from the Local Government Board stating that it was of opinion that the suggestion that Honiton, Ottery St. Mary, Seaton, and Sidmouth urban district councils and the Axminster and Honiton rural district councils should combine and provide an isolation hospital and elect a medical officer of health, who should devote the whole of his time to the duties of the office, would be advantageous to all the districts concerned. The Local Government Board suggested a conference and said it would instruct a medical inspector to be present. After some discussion the council approved of the suggested conference and decided to send a representative. The proposed scheme has been generally favourably received, and recently a large number of ratepayers of Sidmouth signed a petition in its favour.

The Research Defence Society.

The annual meeting of the Devon branch of the Research Defence Society was recently held at Torquay, under the presidency of Dr. J. Harley Gough. There was a large attendance. The report showed that the branch had now 100 members. Sir J. E. Moss, Lord Fortescue, Admiral Sir W. Acland, Sir R. Lethbridge, Sir E. Satow, and Mr. Eden Philpotts wrote expressing regret at their inability to attend the meeting. Mr. Paul Swain gave an interesting address on "Some Recent Gains of Research by Experiments upon Animals."

The Royal Albert Hospital, Devonport.

The annual meeting of the working men's committee of the Royal Albert Hospital, Devonport, was recently held. The report stated that £280 would be available for the institution; this sum was £93 less than that raised in the preceding 12 months. The chairman said that the deficiency was principally due to a decrease in the receipts of the children's demonstration, but he considered they must be satisfied as there was so much unemployment in Devonport.

University of Bristol.

The sixth annual "Long Fox" lecture will be delivered in the Medical Library on Dec. 7th, at 3.45 P.M., by Professor E. Fawcett, the Dean of the Faculty of Medicine, who will take for his subject, "Some Researches in Embryology." The Vice-Chancellor will occupy the chair.

Nov. 30th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

University of Liverpool: New Pro-Chancellor.

Sir John Brunner was elected Pro-Chancellor of the University on Nov. 27th, in the room of the late Sir Edward Lawrence. He is well known in Liverpool as a devoted friend of education. Two chairs at the University owe their foundation to his munificence—the chair of Economics and that of Egyptology, and his advice is believed to have contributed largely to the prosperous financial position of the University.

Female Employment and Infant Mortality: Liverpool Inquiries.

A Home Office Departmental Commission, with the coöperation of the health committee of the Liverpool corporation, has been inquiring into an extremely important aspect of the industrial question—viz., as to the effect which the employment of women has upon infant mortality. The subject has been engaging the attention of the Home Office generally for some time, and a carefully conducted inquiry into the matter has been going on in Liverpool for a period of some 12 months. I understand that, notwithstanding the fact that the industrial employment of women is not common in Liverpool, some very valuable evidence has been collected by the health committee, which will be considered in due course, together with the results of inquiries elsewhere, and will lead, it is anticipated, to some very beneficial results.

Liverpool Royal Infirmary.

At a meeting of the election committee of the Royal Infirmary held on Nov. 25th under the presidency of Mr. Ralph Brocklebank, the chairman of the general committee, Dr. R. J. M. Buchanan, physician to out-patients and assistant physician to the hospital, was unanimously elected an honorary physician. Dr. Buchanan, who is also the professor of forensic medicine at the University of Liverpool, has had a distinguished career at the University Medical School.

Royal Southern Hospital.

The Lord Mayor of Liverpool paid a state visit to St. Paul's Church on Sunday, Nov. 28th, when the anniversary service on behalf of the funds of the Royal Southern Hospital took place. The Lord Mayor was accompanied by the Lady Mayoress and numerous members of the City Council. Representatives from the honorary medical staff and the committee of the hospital also attended the service. The collection realised £92.

Municipal Lunatio Asylums: Are they Needed!

The question has recently arisen as to whether it would not be cheaper for Liverpool to build her own lunatic asylums and maintain her own lunatics instead of discharging those duties in conjunction with the Lancashire Asylums Board, to which Liverpool representatives are sent by the city council. Under the present system the city council and the county council contribute to the cost of the five asylums on a defined basis. In a report on the subject, which contains statistics as to the relative cost of buildings and the maintenance of lunatics in other parts of the country, the town clerk says that the Lancashire asylums board has built the asylums cheaper in some cases than the municipalities who have had sole control of

their own asylums; and the cost of maintenance in the Lancashire asylums is less than in the municipal asylums. If, therefore, the corporation of Liverpool were to build and equip its own asylums the cost per head would probably exceed that already incurred. The town clerk draws attention to the report of the Royal Commission on Local Taxation, 1901, in which it is stated that the Commissioners consider the maintenance of pauper lunatics and the provision of asylums (inter alia) to be services of a national character, and the Association of Municipal Corporations is making representations to the Government with a view to having the same paid for by the State. In these circumstances, the time is not opportune for making any change in existing arrangements. Last year the Liverpool ratepayers paid over £100,000 towards the cost of county asylums and the maintenance of lunatics; hence the question arose in the city council as to the expediency of Liverpool providing her own asylums.

Nov. 30th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Trinity ('ollege and the Royal University of Ireland.

OFFICIAL information has just been made public of the rules which embody the terms of admission of Royal University students and graduates as adopted by the board and council of Trinity College, Dublin. The terms practically mean that the University of Dublin is prepared to accept students of the late Royal University of Ireland according to their standing in that institution without passing any preliminary examinations, and, by a slight rearrangement as to fees, they can continue their education in Trinity College precisely as if they had been original students. Many will avail themselves of these generous terms.

Obituary: Andrew MoConnell, L.R.C.P. & S. Edin.

I regret to record the death of one of the best known of the older Belfast practitioners-Mr. Andrew McConnell, who died at his residence, Belfast, at the advanced age of 71 years, on Nov. 16th, after a prolonged illness of six months' duration, during which he was confined to bed. A native of Doagh, co. Antrim, Mr. McConnell studied at Queen's College, Belfast, and in 1867 became a Licentiate of the Royal Colleges of Physicians and Surgeons of Edinburgh. He shortly afterwards began practice in Belfast; in 1867 he was house surgeon in the union infirmary, in 1869 he became a dispensary medical officer, and at a later period he was appointed visiting surgeon to the union infirmary, a position he resigned a few years ago on account of advancing years. He was an official in the medical service of the Poor-law board for a period of 32 years, and during all that time he discharged his duties with a zeal and conscientiousness worthy of all praise. In 1889-90 he was President of the Ulster Medical Society. He took no part in the public life of the city, being a man of a retiring habit, and thoroughly devoted to practice which, apart from his dispensary clientile among the poor, was large. A devoted student of literature, he was a pleasant companion, and being gifted with a retentive memory he was shrewd and skilful in debate. In private life he was one of the most unassuming of men, and in his work amongst the poor, with whom he was first brought in contact in his professional capacity, he was invariably kind and considerate. Mr. McConnell is survived by his widow, one daughter, and two sons, both of whom are graduates of Trinity College, Dublin. H shane, co. Antrim, on Nov. 19th. He was buried in Brough-

Belfast Charity Organisation Society.

At the annual meeting of the Belfast Charity Organisation Society held on Nov. 29th attention was drawn in the report to the fact that the society has decided to adopt a scheme for the collection of subscriptions to the various charities, the association acting as the central agency. It is to come into force in next January. The principal medical charities, however, like the Royal Victoria Hospital and the Mater Infirmorum Hospital, have refused for various reasons to come in, so that the scheme is merely an experiment. Attention was also drawn in the report to the proposed reform of the Poor-law system, but many feel, so far as Ireland is concerned, tha enough attention has not been

SCOTLAND.—PARIS.—ITALY.

drawn to the medical side of the question in that country in either the Minority or Majority reports. The amount spent by the Belfast Charity Organisation Society during the past year in relief of distressing cases was £475, as compared with £418 the previous year. More money is wanted both for the general expenses of the administra-tion of the society and for relief of cases, but this unfortunately is now the condition of almost every philanthropic agency and, with increased demands, this state of affairs is unfortunately likely to be intensified. Nov. 30th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Medical Defence Union of Scotland.

THE seventh annual report of this society, the objects of which are to safeguard the interests of its members, to give legal advice, and to promote the interests of the profession generally, was presented at the annual meeting recently held at the offices of the Union, 155, St. Vincent-street, Glasgow. The report shows that the year ending August, 1909, was one of progress, and it is satisfactory to note that out of a large number of claims against members only a small proportion of actions at law ensued. The membership at the close of the year under review was 1189. The income for the year was £631 10s., and the expenditure £337 7s., leaving a balance of £294 odd. The expenditure amounted to only 53 per cent. of the income, and was equal to about 5s. 8d. per member. The report gives details of an insurance scheme against the risk of damages being awarded against members in connexion with their professional work. A premium of 6s. insures against £500 damages and costs, and 10s. against £3000 damages and costs. The entrance fee to the union is 10s., and the annual subscription 10s., but members of any English society having similar objects to the Scottish Union are admitted without entrance fee.

University of St. Andrews and the Proposed Changes in the Medical Curriculum.

A meeting of the University Court of St. Andrews was held on Nov. 20th when there was submitted the draft of a proposed ordinance for alteration of the regulations for graduation in medicine, which had been prepared by the Board of Studies in Medicine, and also by a conference of representatives of the Universities of St. Andrews, Glasgow, and Aberdeen. It was reported that the terms of the ordinance had been fixed by the conference after careful deliberation, so as to provide a basis of uniformity among the three universities in all the main provisions. The Court resolved to adopt the document as a draft ordinance, and resolved to communicate it to the Senatus Academicus and the general council of the University, and to invite the views of these bodies thereon, in conformity with the provisions of the Universities (Scotland) Act, 1889, as regards ordinances.

Forfarshire and the Prevention of Consumption.

At a meeting of representatives of the four district committees in Forfarshire, held in Arbroath on Nov. 20th, Dr. N. J. Sinclair, medical officer of health of the county, reported that the measures adopted last year for dealing with phthisis had been of great value. Since May last 14 deaths from phthisis had been notified—7 in Buchan, 4 in Forfar, 2 in Dundee, and 1 in Arbroath. For a period of 10 or 12 years back not more than five deaths had occurred in any year in the Arbroath district, which was practically free from phthisis. It was agreed that the lectures and other means adopted during the past year for the diminution of consumption should be continued.

Nov. 30th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Rotation of the Femur in the Treatment of Congenital Dislocation of the Hip-joint.

THE question of rotation of the femur in the treatment of congenital dislocation of the hip-joint was discussed by M. Le Damany at the recent congress of the French Surgical Association. He said that as congenital dislocation of the hip-joint had excessive torsion of the femur for its principal

cause, rational treatment would, among other matters, include reverse rotation of this bone. The soundness of this view was shown by proofs of two kinds, mechanical and clinical. For the mechanical proof an apparatus was used to demonstrate the fact that under the given conditions reverse rotation was possible. The clinical proof was equally convincing, for the results obtained by this method in the treatment of children were far superior to those furnished by immobilisation in plaster splints.

Use of Colloidal Metals for the Prevention of Surgical Infections.

At the same congress of the Surgical Association M. M. Cazin said that during the last two years he systematically used colloidal metals in about a hundred cases for the Electrically prepared prevention of surgical infections. palladiol was the preparation which he preferred, with electrargol as the next beso. He employed one of these substances whenever he encountered suppuration whilst operating—principally in cases of "cold" appendicitis and in suppurations of the adnexa. He also made use of them as prophylactics, not waiting for the occurrence of symptoms of general infection but commencing the treatment the day before an operation, when that was possible, or at least giving a first injection some hours beforehand. The doses to which he had recourse were much larger than those usually recommended. Patients who had been operated on and were in danger of infection might, in his opinion, have daily injections of 40 or 50 cubic centimetres, and even more, of either the palladiol or the electrargol without experiencing the slightest ill-effects. M. Victor Henri had shown that daily injections of 10 cubic centimetres of electrargol were harmless to rabbits, and M. Cazin had never observed any untoward result after injections repeated for several days in succession until the complete disappearance of the pyrexia. He had used the treatment in very severe suppurative conditions connected with the appendix and the Fallopian tubes. In 100 cases of abdominal surgery for septic lesions he had lost only one patient, a female whose general health was extremely bad and whose circumstances were such that she did not receive proper treatment after the operation.

Medical Diplomas in France.

During the last full academical year the number of diplomas of Doctor of Medicine granted by the French faculties of medicine in the several cities was as follows: l'aris, 430; Bordeaux, 147; Lyons, 137; Montpellier, 102; Toulouse, 58; Lille, 46; and Nancy, 35. The Faculty of Medicine at Beyrouth in Syria, whose degrees are recognised by the French Government, granted 30 diplomas.

Treatment of Hydatid ('yst of the Liver.

At a meeting of the Surgical Society held on Nov. 17th, M. Quénu gave details of two cases of hydatid cyst of the liver which M. Dujarier had treated by extirpation after disinfection by formalin and in which union had been obtained by suturing. In the first case drainage was maintained for two days and recovery was uneventful. The second case was one of multiple cysts which were treated in the same waynamely, by "formalisation" and removal of the membranes The patient belonging to the parent cyst, and suturing. made a rapid recovery. Nov. 30th.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

Another Italian Scourge.

MALARIA is on the wane, pellagra is following suit, but the great sin of great cities" (or premature indulgence in the marital privilege) is on the increase, reinforced by yet another and hardly less deadly vice—alcoholism. Hooked on to the and nardy less deady vice—accondism. However the water express train of the twentieth century, Italy is forging ahead "for better, for worse," in some respects distinctly for the latter. Like all southern nationalities she was wont to compare honourably with her transalpine sisters in the use of strong drink, but now she is rapidly descending from that "coign of vantage," and alcoholism, with its train of sinister sequelæ, is among the most formidable of the enemies, physical and social, with

which she has to cope. By every test which the anthropologist can apply, stunted development of mind and body becomes more and more common among her youth, and not a day too soon the best of her citizens are exerting themselves to track down the causes and replace them by conditions that make for health and manhood. The "Federazione Antial coolista Italiana" and the "Lega Popolare Control'Alcolismo" have been strenuously at work in this direction, and the statistics they have compiled in the course of their crusade more than justify their organisation and enterprise. Medical practitioners and consultants have joined "head and hand" with them and, as a result, the public are at length aroused to the prevalence of the evil and bringing pressure to bear on the authorities, municipal and imperial, to curb and conquer it. Some of the evidence contributed by physicians as to the increased resort to stimulants among the labouring classes seems impressive enough, particularly to all who can compare the Italy of last century with the Italy of to-day. the Marches (writes a local practitioner) the peasant in the busy season drinks from 20 to 25 tumblers of wine per diem! Within the last quarter of a century the number of victims to "psicose alcooliche" (mental diseases from strong drink) have been "quadrupled." In the "manicomio" (madhouse) of Brescia the proportion of admissions for alcoholism was 37.1 per cent. for the past year. At the Thirteenth Congress of Medico-Psychologists held in Florence in 1907 Dr. Paolo Amaldi thrilled his audience with statistics equally startling; and Professor Antonini of Udine capped his confrere's returns with others of even graver import. The last-named expert added some details as to the causes of aggravated alcoholism in the Venetian population, among them being "the temporary emigration of the labouring classes during summer and their return in the winter months, having acquired drinking habits during their northern sojourn which stick to them throughout their idle spell." Worse still is the record of the urban population, especially in the great centres like Milan or Turin. In the former city, according to Dr. Angelo Arcelli, whose "inspection" comprised some 40,000 young pupils of both sexes, 83.50 per cent. are habitual consumers of "sostanze alcooliche" (articles of diet impregnated with alcohol), 44.22 per cent. drink "liquori" (vermouth and such like, also charged with alcohol), and 5 per cent. are sometimes drunk! Needless to add the testimony of their teachers that the young abstainers are quite the better behaved and the more intelligent, the wine or liquor drinkers being physically, intellectually, and morally quite inferior. The anti-alcohol crusade, conducted by the two associations—the "Federazione" and the "Lega" above referred to—has elicited important evidence as to personal habits and experience from prominent physicians and other "men of light and leading" throughout Italy. Two questions (first, Do you habitually take wine at or between meals; and second, Do you think alcoholic drinks, fermented or distilled, conducive to intellectual work or to "ispirazione geniale" (genial inspiration)?) have elicited from these authorities an expression of opinion that in some cases the moderate use of wine is salutary, while in others abstinence is the wiser course. Among the medical and biological authorities who represent the "moderate" side are such commanding names as Bianchi, De Giovanni, Morselli, Mosso, and Murri-Mosso maintaining that wine, sparingly consumed, is a sounder and more sustaining beverage for the worker than water, and certainly a preservative against many maladies. Historians like Villari and Ferrero are also believers in "moderation"—the latter (whose brilliant studies in Roman history are now familiar to the English-speaking world) going so far as to say that "he has always found at the bottom of a flask of champagne some idea, subsequently to be elaborated with patience and profit during hours of fasting." In other fields of mental energy—poetry, painting, sculpture—the evidence oscillates between "moderation" and abstention; while all the testators seem at one in holding that, to promote habits of strict sobriety among the less favoured classes, it would be well if the more favoured denied themselves even moderate indulgence in wine, were it only, by the force of example, to strengthen the hands of those who are labouring to wean young Italy from what is even now a "scourge" and may yet become a permanent and all-pervading source of national "decline and fall. Nov. 27th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Recent Epidemic of Poliomyclitis.

THE official report of the committee appointed for the study of the recent epidemic of poliomyelitis in Vienna was presented by Dr. Lappert at the last meeting of the Prediatric Society of this city. It stated that 290 cases were reported upon, but that only 266 could be made use of in the report; it may also be remarked that 90 additional cases were observed after the report had been drawn up. Of the cases considered in the report 129 were from Vienna, and 137 from the surrounding districts. The epidemic commenced in July, 1908, and reached its climax in October. The ratio of girls to boys was as 72 to 100. The age was mostly between one and three years. Social position and density of population did not seem to have any influence. Of the 266 cases 241 showed the spinal type with paralysis of the legs, especially on the left side. Affections of the muscles of the back, the neck, or abdomen were noticed only rarely. In 14 cases, where the patients were older, a special feature of the disease was ascending and descending paralysis with death from involvement of the respiratory centre. Symptoms referred to the pons Varolii and medulla oblongata occurred in 25 cases. Mostly paralysis of the ocular muscles, of the facial nerve, and of the muscles of deglutition was seen in combination with the spinal type. These cases generally improved quickly. In some cases only the cranial nerves were affected. The encephalitic type with spastic hemiplegia was very rare. The so-called polyneuritic type could not be recognised as a special form. The meningitic type was without doubt also present, but could not be considered in the report as the observations were not reliable. The course of the disease was generally the following. A prodromal stage, lasting from one to four days, with pyrexia, sleeplessness, sore-throat, and gastric disturbances, was very often seen. From two to four days after the prodromal symptoms paralyses supervened, affecting different parts of the body, reaching their maximum after a few days and then diminishing to some extent. The temperature rarely reached 39°C. The statistics showed that 10 per cent. of the patients died and that 13.5 per cent. were reported recovered, but this figure will undoubtedly be added to. The other cases showed a persisting paralysis of one or more groups of muscles. In Vienna no connexion of cases could be discovered, the distribution being quite irregular, but the disease appeared in families and amongst neighbours, which suggests that it should be considered infectious.

A Case of Erythrocythæmia.

At a recent meeting of the Ophthalmological Society Dr. Krämer showed preparations obtained from a man who had suffered from morbus cæruleus congenitus. He was 19 years old and was said to have been always cyanotic. He was liable to slight asthmatic attacks and used often to spit up blood without pyrexia or any pulmonary symptoms being present. The visible mucous membranes were of a deep violet colour, whilst the face, nose, fingers, and ears were bluish-red. Systolic murmurs were heard all over the heart. The blood showed 6000 leucocytes and over 9,000,000 red corpuscles in the cubic millimetre. The conjunctiva of the tarsus was dark red. The lens and vitreous body were clear; the veins of the fundus were four times the size of those seen in a normal fundus; the visual acuity was 6/18. Both eyes had an identical appearance. The veins were nearly black and much curved; the arteries also were of a dark colour and twice their ordinary size. There were no extravasations of The patient died suddenly with symptoms of blood. internal hæmorrhages. The abnormalities found at the necropsy included narrowing of the pulmonary artery to the size of a lead pencil, a defect in the ventricular septum of the heart, a pervious condition of the foramen ovale, recent endocarditis, and an infarct of the lungs. As Dr. Krümer said, cases like this one were very rare, so that the ophthalmological conditions have as yet been little studied.

Eventful Career of a Medical Student.

A remarkable case came before the courts a few days ago when a medical student of more than ordinary ability was tried on a charge of forging banknotes. The evidence showed

that he had, before completing his curriculum, found out that there was a focus of tropical malaria on the outskirts of Vienna. The disease had, up to the time of his inquiries, been regarded as either typhoid fever or meningitis or simply "a fever"; he was the first to recognise its true nature and to urge on the authorities the necessity of making special efforts assertions; and the board of public health in the affected district ridiculed the student's researches, advising him to finish his studies first and afterwards to correct his ideas. A memorandum sent by him to the chief board of health was also without effect, although it was read there and approved. He therefore began to treat the patients according to the diagnosis he had arrived at by his researches, and, although unrecognised officially, he soon became known in the district as the malaria doctor who did wonders in restoring people to health. He neither asked for nor received money from the patients, who were, in fact, the poorest of the poor, and he himself was hardly able to procure the necessaries of life. Eventually he applied to the municipality for a grant, which was refused, and then, being in the direst necessity, nearly starving, he began to forge banknotes, as he was an expert photographer. When before the court he put forward the plea that the loss suffered by the State through his attempt at forging was more than compensated by the good which he had done in restoring to health so many otherwise incurable persons, and in the result he was acquitted by the jury on the ground that "irresistible coercion" had made him do what he did. Many bitter things were said in court against the official representatives of medicine, together with repeated references to the fate of Dr. Kolles, who in spite of his discovery of the value of cocaine in medicine had to leave Vienna a broken man, as well as to the fate of Semmelweis, whose immortal discovery of the cause of puerperal infection was treated in such a way that the discoverer's mind was permanently injured. Unlike them, however, this adventurous student has now met with sympathy and is out of danger as far as monetary interests are concerned.

Nov. 29th.

NOTES FROM INDIA. (From our own Correspondents.)

Quinine Distribution.

It is to be hoped that one result of the Malaria Conference at Simla will be a reduction in the prices charged for quinine made at the two Government factories at Darjeeling and in the Nilgiris. These prices should be strictly regulated by the rates in the open market, and there should be no attempt to show a profit merely for the sake of justifying the existence of the factories. Provincial administrations are ordered to obtain their supplies of drugs from the Government stores, and they very naturally resent the expenditure involved in the transactions, which becomes considerable when large quantities of quinine have to be purchased during epidemics of malaria. It should be possible to arrange a sliding-scale of prices which would follow those quoted by wholesale chemists. If there is a loss in the working of their factories, the Government of India should inquire into the methods of manufacture and take expert advice as to the possibility of improving the processes by which quinine is produced. The local government of Burma has issued an important resolution contained in a circular enumerating measures to come into force from Jan. 1st for the introduction of a revised system for the sale of, and free distribution of, quinine throughout the province. The Lieutenant-Governor of Burma has decided to increase the number of fixed centres for the sale of quinine in all bazaars throughout the province. For the areas which are not within easy reach of a post-office or bazaar it will be necessary to select headmen of village tracts to act as vendors. By these means it should be possible to put quinine within the reach of every inhabitant of the country. It will not be necessary to discontinue the sale of quinine through the agency of Government servants now acting as vendors, but their number should not be unduly increased so as to discourage the efforts of those who may conveniently be termed stationary vendors. To stimulate the sale the price of the drug will be lowered and the profit of the retail vendor increased. Free distribution will only be made (a) to those unable to purchase, (b) in outlying areas where there are no bazaars, post-offices, or headmen to act as vendors, and (c) in case of widespread outbreaks of malaria.

The St. John Ambulance Association.

The Indian branch of the association, with the authority of His Excellency the President, has just published a pamphlet giving full details of the work of the association in India. The pamphlet is divided into five chapters as follows: (1) The Order of St. John and its Associations with the Ambulance Movement; (2) the St. John Ambulance Association; (3) the Value of an Ambulance Training; (4) How to Organise Centres and Classes; (5) the St. John Ambulance Brigade. These chapters, as the titles indicate, contain full information with regard to the origin and development of the association and its Indian branch, the method of organising centres and classes and full details with regard to the issue of certificates, and the methods of obtaining ambulance stores and forming units of the St. John Ambulance Brigade. The syllabuses of the various courses of instruction controlled by the association are given in a sixth chapter, and as appendices are given the regulations for the next competition for the following:—1. The Indian Railway Challenge Shield, presented by H.R.H. the Grand Prior and the Chapter of the Order of St. John. This competition will be held at Jubbulpore on March 2nd, 1910. 2. The Volunteer Corps of India Challenge Shield, presented by H.R.H. the Grand Prior and the Chapter of St. John of Jerusalem in England. The date and place of this competition will be fixed by the Inspector-General of Volunteers in consultation with the corps concerned. 3. The first annual competition for the challenge cup, presented for competition amongst divisions of the St. John Ambulance Brigade, by Mr. Vivian Gabriel, C.V.O., to be held at Lahore on Dec. 27th, 1909. The pamphlets can be obtained free on application to the Honorary Secretary, St. John Ambulance Association, Indian Branch, Peshawar, or the Honorary Secretary, Executive Committee. Viceregal Lodge, Simla, or from Honorary Manager, Stores Depôt, Sassoon Institute Building, Bombay.

Health in Indian Jails.

The Sanitary Commissioner's note on mortality in jails recently issued shows that in 1908 all the conditions in-fluencing the health of the prisoners were extraordinarily unfavourable. The south-west monsoon of 1907 receded prematurely and in consequence the spring crops of 1908 were bad everywhere excepting in Eastern Bengal and Assam and in Lower Burma, and although the autumn crops were generally good, except in Bengal, the epidemic of malarial fever which ravaged Upper India delayed the harvest. Poor and belated harvests raised the already high prices. High prices led to an increase of orime and the number of prisoners admitted into the prisons rose from 291,165 in the preceding year to 341,831, a total increase equal to 17 per cent. The increase was not, however, equally distributed. It was 50 per cent. in the Central Provinces, 28 per cent. in Bengal and the Punjab, and 26 per cent. in the United Provinces. Tubercle or diseases of the lungs, or both, levied a higher toll of death than usual. Not only were many of the prisons continuously overcrowded, but a large proportion of the newly admitted prisoners were in a bad state of health owing to the effects of scarcity and malaria infection. In India and Burma the mean daily prison population in 1908 was 101,336, compared with 93.264 in the previous year. In every 1000, 646 were admitted to hospital during the year, and 29 were constantly on the sick list, compared with 624 and 27 respectively in 1907. The death-rate, which in the previous five years ranged from 19.50 in 1903 to 17.61 in 1904, rose to 24.17, or 6.45 per 1000 more than in 1907. Every administration, except Bombay and the North-West Frontier Province, shared in the increased mortality; the most striking advances in the death-rate, compared with 1907, being from 16.94 to 31.61 per 1000 in Bengal; 18.79 to 29.80 in Madras; and 15.03 to 24.09 in the United Provinces. The average daily number of convicted prisoners in confinement was 94.262, and among them the death-rate was 24.32 per 1000, ranging from 31.96 in Eastern Bengal and Assam to 13.09 in Burma, the rates being under 20 per 1000 only in Burma, the North-West Frontier Province, and Bombay.

The Malaria Conference.

The subcommittee, consisting of Mr. R. Nathan, I.C.S., Colonel Thornbill, I.A., and Major L. Rogers, I.M.S., which on the recommendation of the Malaria Conference visited certain places in the Punjab in connexion with the malaria inquiry, has returned to Simla, where it will draw up its report.

Plague.

The returns for the week ending Oct. 23rd show that 4815 seizures and 3992 deaths from plague occurred throughout India during the week, both figures being slightly less than those for the previous seven days. The mortality in the different provinces was as follows: in Bombay Presidency, 1067 deaths; in Madras Presidency, 121; in Bengal, 50; in the United Provinces, 338; in the Punjab, 354; in Burma, 16; in the Central Provinces, 1142; in Mysore State, 161; in Central India, 364; and in Rajputana, 354. In Nagpur City the deaths for the week under report numbered 786

Oct. 25th.

Medical Rebs.

FOREIGN UNIVERSITY INTELLIGENCE. Bologna: Dr. A. Malagolli has been recognised as privatdocent of Prediatry.—Cagliari: Dr. L. Trincas has been recognised as privat-docent of Bacteriology.—Cordova (National University): Dr. Benjamin Galindez has been appointed Professor of Descriptive Anatomy in succession to Dr. Luis M. Allende.—Grat: Dr. Rudolf Müller has been appointed Extraordinary Professor of Pharmacourans been appointed Extraordinary Professor of Pharmacognosis. Modena: Dr. Carlo Aldo Massaglia has been recognised as privat-docent of General Pathology. -Padua: Dr. Enrico Opocher has been recognised as privat-docent of Midwifery and Gynæcology. - Palermo: Dr. Franco Bommarito has been recognised as privat-docent of Urology.—Parma: Dr. Mario Varanini has been recognised as privat-docent of Internal Pathology.—Philadelphia Medical College: Dr. Philip Fischelis has been appointed Adjunct Professor of Histology and Dr. Herbert J. Smith Adjunct Professor of Therapeutics and Materia Medica.—Prague (German University): Dr. Wilhelm Wiechowski has been appointed Extraordinary Professor of Pharmacology, and Dr. Edmund Weil has been recognised as privat docent of Hygiene.—Rome: Dr. G. Mari has been recognised as privat-decent of Internal Pathology, and Dr. V. Nicoletti as privat-docent of External Pathology, —Sienna: Dr. Vincenzo Beduschi has been recognised as privat-docent of Neurology and Psychiatry.—
Turin: Dr. C. Tovo has been recognised as privat-docent of Forensic Medicine.

THE TREATMENT OF .SCHOOL CHILDREN.—The Havant board of guardians has been recently corresponding with the Local Government Board upon the subject of the treatment of school children found to need medical attention and whose parents were unable to pay for the same, and the letter from the Local Government Board showed clearly that they were prepared to approve of boards of guardians making special arrangements for the treatment of these cases. The Havant board of guardians has now decided to use these powers and, with the approval of the Local Government Board, has fixed a fee of £2 for the operative treatment of cases of enlarged tonsils and adenoids by the district medical officer. Other boards of guardians may follow this lead and take advantage of the Poor-law medical service in order to deal with such defects among poor children.

THE BRITISH WHITE CROSS MILK COMPANY.—
This company opened its factory at Knebworth on Nov. 20th by a ceremony which, on the invitation of the company, was attended by a large number of guests, including several well-known members of the profession. Lord Lytton, the chairman of the company, who presided at the luncheon, supported by many of the directors, explained the objects and methods of the company and proposed the toast of its success. After this had been supported briefly and suitably by other speakers the guests made a tour of inspection and had an opportunity of seeing the process at work. Later they were conveyed in motor-cars to Knebworth House, where they were received by the Chairman of the company and

Lady Lytton. The objects of the company, stated very briefly, are to provide the public with a milk which shall be absolutely free from pathogenic germs and uniform in the proportion of its respective constituents while remaining altogether unimpaired in its nutritive and Calorie values by the process which ensures the attainment of these ends. At some future time we may have an opportunity of testing these claims, and shall then be in a position to advise our readers of their validity. In the meantime, it is safe to say that every precaution seems to be taken to prevent the contamination of the milk during the process of its preparation in the factory.

HOSPITAL SUNDAY FUND AT BRISTCL.—The annual meeting of the committee of this fund was held on Nov. 25th. The report stated that the fund for 1909 amounted to £1929, an increase of about £40 compared with 1908. The following grants were made: Royal Infirmary, £739; General Hospital, £620; Children's Hospital, £239; the other medical institutions received about £108. It was decided that Jan. 30th should be observed as Hospital Sunday for 1910, when a strong effort will be made to raise £2000.

THE METROPOLITAN HOSPITAL SUNDAY FUND.—A meeting of the Council of the Metropolitan Hospital Sunday Fund was held at the Mansion House on Nov. 30th under the presidency of the Lord Mayor. The report for the year 1909, which showed that the total collection amounted to £72,650, having been adopted by the Council, it was decided that the annual meeting of the constituents of the Fund should be held on Dec. 17th, and it was agreed that next llospital Sunday should be held on June 12th, 1910. It was announced by the secretary that the Rev. Lionel Lewis had given notice that he would move at the annual meeting that the law of the constitution should be elected by the constituents.

THE EPILEPTIC COLONY OF THE LONDON COUNTY COUNCIL AT EPSOM.—Proposals for the extension of the epileptic colony at Epsom were submitted to the London County Council by the asylums committee on Nov. 30th. The committee asked that a scheme be sanctioned for the erection of two new villas for patients, a new central bathroom, and additional quarters for the staff at a total cost of approximately £12,760. In explaining why the proposed work was necessary the committee gave details as to the way in which the colony is carried on. It was opened in 1903 and had accommodation for 273 male and 60 female patients. These were all epileptics, but they were also certified lunatics, the colony being a county asylum established under the Lunacy Act, 1890. Two conditions were observed in the selection of colonists—their physical fitness to share in the labour (chiefly agricultural) carried on as part of the treatment, and the possibility of their being granted a measure of personal liberty within the colony grounds to an extent not possible in an ordinary asylum. This liberty, granted on parole, was a valued privilege at the colony. Originally patients sent to the colony were always selected from those who had been admitted in the first instance to some other asylum. Recently patients stated in the application form to be epileptic had been sent to the colony direct, and had been kept there for a time to ascertain whether they were fit for the special conditions of colony life, unsuitable cases being removed elsewhere. This practice, however, had only been possible to a limited extent owing to the lack of proper reception accommodation at the colony. The committee was satisfied that if the main features of the institution as a working colony were to be retained provision must be made for the reception of all acute recent male epileptic patients, from amongst whom suitable workers could be selected for retention, unsuitable cases being drafted elsewhere. An admission villa to accommodate 50 patients was necessary, and this extension on the male side would necessitate an increase in the number of chronic female epileptic workers (at present only 60) in order that the extra domestic and laundry work might be coped with. An extension of the staff block would also be necessary. The committee recommended the provision of a central bathroom because it would allow the head attendant or other responsible senior officer always to be present when bathing was going on. This was a matter of much importance, as at present it was impossible, with bathing proceeding simultaneously in the different villas, to exercise a check upon any possible ill-treatment of patients, as shown by the presence of bruises. The provision of spray instead of slipper baths was recommended on the ground that economy in the use of coal would be effected. The whole cost of the work worked out at £151 a bed, which the finance committee regarded as a reasonable figure. The committee's recommendations were approved.

THE MIDDLESEX HOSPITAL.—At last week's meeting of the governors of the Middlesex Hospital Major-General Lord Cheylesmore, the chairman, in moving the adoption of the report, said that in spite of the exercise of rigid economy the ordinary maintenance expenditure had exceeded the revenue by £12,500, thus bringing the total deficit to £20,000, which had compelled the governors to go again to their bankers for a loan to meet their obligations. He appealed most earnestly to the public for further support for the institution. Part of a discretionary bequest of £5000 left by the late Lady Goldsmid was to be devoted to the endowment of two beds, one in the general wards, the other in the cancer wards, in memory of the testatrix, and the residue was to be applied to the general purposes of the cancer fund, or on behalf of the investigation department, as the board might determine. Mr. E. T. Hall had been chosen to prepare plans and superintend the erection of the new cancer buildings on a site abutting on the hospital premises, a long lease having been granted by Mr. Charles Berners, a member of the board, on very moderate terms. The board asked sanction to alter the laws of the hospital to provide for the creation of the office of assistant ophthalmic surgeon, the qualifications to be the same as those for ophthalmic surgeon. for the adoption of the report was seconded by Mr. Reginald Lucas and carried unanimously.

THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY: PROPOSED INSURANCE AGAINST DAMAGES OR Costs.—Dr. G. A. Heron, the treasurer and chairman of the council of the London and Counties Medical Protection Society, explained to the members of that society at a special general meeting held at 31, Craven street, Strand, on Nov. 24th, the proposal of the council to arrange for an insurance of the members of the society against any damages or costs up to £2000, which might be awarded at any time against any member in any proceedings which the society might undertake on behalf of its members. For that For that purpose the subscription to the society would be raised to a sum not exceeding £1 per annum. Dr. Heron stated that the council desired to secure a form of assurance from an insurance company which would cover the risks of a member of the society as to costs and damages given against him in any trial at law in which his case was undertaken by the society, and in which he was unsuccessful, or which was settled either in or out of court. More than one proposal for the covering of these risks by insurance was in course of consideration by the council. Dr. Heron assured the members present that the council on their behalf would strictly guard their right to conduct the trial at law in the way the council might think proper. secure that end the council would keep in their own hands the right to defend and to refuse or cease to defend, to settle and to decline to settle in or out of court any case submitted to the council by a member of the society. The proposed assurance would leave the members of the society exactly where they now stood with regard to the council of the society, but each member would have the comfort of knowing that he had a material sum assured to him with which costs and damages given against him in an unsuccessful action at law would be met. The sum to which each member would be entitled to look from his assurance against costs and damages given against him in an unsuccessful action at law would amount to at least £2000 in any one year, but the actual amount must be left to the council for final settlement. Dr. Major Greenwood contended that the plan would not have a good effect on medical men in their relation to the public; in fact, the proposed absolute insurance was bad for the public, for the medical profession, and for the society. After a long discussion the meeting passed a resolution approving the action of the council in arranging for an insurance of the nature proposed, Dr. Johann Hermann Baas of Worms, aged 71 years. His

the subscription to the society for that purpose to be raised to a sum not exceeding £1 per annum.

The honorary membership of the Italian Society of Obstetrics and Gynacology has been conferred on Dr. H. Macnaughton-Jones.

MEDICAL MAGISTRATE.—The deputy mayor of Rotherham, Mr. G. H. Lodge, L.R.C.P., L.R.C.S. Edin., L. F. P.S. Glasg., has been appointed a Justice of the Peace or the borough of Rotherham.

RICHARD MIDDLEMORE POST-GRADUATE LEC-TURES, BIRMINGHAM.—The annual lecture under this endowment will be delivered at the Birmingham and Midland Eye Hospital, by Mr. H. Eales, on Dec. 21st, at 5 P.M. The subject will be Myopia. All qualified members of the medical profession are invited to attend.

DISTRICT MEDICAL OFFICERS AND CONSULTA-TIONS. -At the last meeting of the St. Columb (Cornwall) board of guardians it was decided to apply to the Local Government Board for sanction for the payment of 1 guinea, being the fee for a consultant called in by one of the district medical officers for a parish patient.

COTTAGE BENEFIT NURSING ASSOCIATION.—The half-yearly general council meeting of this association will be held in Denison Hall, 296, Vauxhall Bridge-road, London, S.W., on Tuesday afternoon next, Dec. 7th, at 2.45 P.M., when the Hon. Sydney Holland will speak on "The State Registration of Nurses.

SOUTH DEVON AND EAST CORNWALL HOSPITAL. As a result of the Hospital Sunday collection which took place in Plymouth on Oct. 24th the sum of £737 has been handed to the treasurer of the South Devon and East Cornwall Hospital. A sum of £551 has also been received as a result of the Hospital Saturday collections, which took place on July 17th.

MEDICAL SICKNESS AND ACCIDENT SOCIETY .-The usual monthly meeting of the executive committee of the Medical Sickness, Annuity, and Life Assurance Society was held at 429, Strand, London, W.C., on Nov. 19th. There were present: Dr. F. de Havilland Hall, in the chair, Mr. J. Brindley James, Dr. J. Pickett, Dr. Frederick S. Palmer, Dr. F. C. Martley, Dr. M. Greenwood, Mr. F. S. Edwards, Dr. W. A. Dingle, Mr. E. Bartlett, Dr. F. J. Allan, Dr. W. G. Dickinson, Mr. J. F. Colyer, Dr. W. Knowsley Sibley, and Dr. J. B. Ball. The committee passed a resolution, expressing to Mrs. Clutton, widow of the late Mr. H. H. Clutton, for many years one of the treasurers of the society, their deep sense of the loss they have sustained by his death and their sympathy with her in her bereavement. A more than usually long list of sickness claims was considered, but, although numerous, the claims were for the most part of a light nature and of short dura-tion. The financial results of the society's working are very satisfactory, and although the current year has still some weeks to run it is clear that when the books are closed in December a considerable addition will be found to have been made to the invested funds. Prospectuses and all particulars may be obtained on application to Mr. F. Addiscott, Secretary, Medical Sickness and Accident Society, 33, Chancery-lane, London, W.C.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.-The deaths of the following eminent foreign medical men are announced: -Dr. C. F. Larsen, a well-known Norwegian authority on tuberculous disease, in his eightieth year.—Dr. Axel Otto Lindfors, professor of midwifery and gynæcology in the University of Upsala.—Dr. Mayet, formerly professor of general pathology in the University of Lyons.—Dr. S. Bubnoff, professor of hygiene in the University of Moscow.—Dr. George E. Stubbs, formerly professor of surgery in the Medico-Chirurgical College, Philadelphia.— Dr. Manuel Beguerestain, surgeon and gynacologist to the Rawson Hospital, Buenos Ayres.—Dr. Paul Fraisse, extraordinary professor of zoology in the University of Leipsic, whose researches in embryology are well known. He had

name is known in connexion with phonometry and with works on the history of medicine, one of which has been translated into English and published in New York.—Dr. Charles H. Cobb, professor of therapeutics and materia medica in the College of Physicians and Surgeons, Boston.-Dr. Pierre Merlon, French Ambassador in Peru.—Dr. Arturo Marini, a Genoa gynæcologist.—Dr. Fauvel of Havre, a wellknown surgeon in that port.

XFORD AND MEDICAL POOR-LAW RELIEF.—At a public meeting held at Oxford on Nov. 30th, under the auspices of the city branch of the Christian Social Union, a resolution was proposed asking the board of guardians to encourage sick persons unable to pay for medical attendance to apply for medical relief; and also asking the board to make it known that persons with families who have incomes under 22s. a week would not be required to repay the cost of the relief or appear before the board. The resolution was supported by a letter in its favour from Dr. W. Osler, Regius Professor of Medicine, and was carried nem. con.

Schools and MEDICAL GRADUATES' Association.—The autumn general meeting of this association was held on Nov. 24th at the Hotel Cecil, the President, Dr. F. A. de T. Mouillot, of Harrogate, being in the chair. Amongst other members present were Sir Alfred Keogh, K.C.B. (President-elect), Sir Charles Cuffe, K.C.B., Dr. P. S. Abraham, Mr. T. Hobbs Crampton (chairman of council), Mr. M. Bulger, Dr. J. E. Macdonald, and the secretaries, Dr. W. Douglas, Mr. G. W. Dawson, and Mr. Campbell Boyd. After the meeting a banquet was held at which Lord MacDonnell, K.C.V.O., was the principal guest. In replying to the toast of "The Guests," he mentioned that he was very nearly being a member of the association himself, having whilst a student at Queen's College, Galway, prepared for the first examination in medicine. During his service in India his relations with members of the medical profession were always most cordial. He took particular pleasure in being present, as one of his brothers helped to found the association.

University of London: Meeting of the MEDICAL FACULTY.—A meeting of the Medical Faculty was held at the University on Tuesday afternoon last, Nov. 30th, when, in the absence of the Dean, the chair was taken by Dr. F. H. Champneys, chairman of the Board of Advanced Medical Studies. There was no quorum, but two important reports from the committee were considered and amended. The first report had reference to the conduct of the work of the Faculty, and was as follows :-

Whilst considering the previous recommendations of the Faculty adopted on March 12th and 26th, 1909, to be the best arrangement for conducting the work of the Faculty, the committee recommend the adoption of the following resolutions:—

(a) That a committee of the Faculty be appointed which shall deal with matters referred to the Faculty and report thereon to the Faculty.

Faculty.

(b) That this committee be constituted as follows: (i.) The Dean of Faculty of Medicine, who shall be ex officio chairman of the Board. (ii.) The secretary of the Faculty of Medicine. (iii.) The chairman of the Boards of Studies in the following subjects: Preliminary Medical Studies, Intermediate Medical Studies, Advanced Medical Studies, Dentistry, Pharmacy (when appointed), Hyglene and Public Health, Physiology and Experimental Psychology, Human Anatomy and Morphology. (iv.) Two representatives of the Board of Preliminary Medical Studies to be appointed from the members of the Faculty by the Faculty after report from the Board in question. (v.) Two representatives of the Board of Intermediate Medical Studies to be appointed from the members of the Faculty after the Paculty by the Faculty after the Paculty by the Faculty after the Paculty by the Faculty after the Paculty by the Faculty after the Paculty by the Faculty after the Paculty by the Faculty after the Paculty by the Faculty after the Paculty by the Faculty after the Paculty by the Faculty after the Paculty by the Faculty after the Paculty by the Faculty after the Paculty by the Faculty after the Paculty by the Faculty after the Paculty by the Faculty after the Paculty by the Faculty after the Paculty by the Paculty by the Paculty by the Paculty by the Paculty after the Paculty by the Paculty by the Paculty by the Paculty by the Paculty by the Paculty by the Paculty by the Paculty by the Paculty by the Paculty by the Paculty by the Paculty by the Paculty by the Paculty by the Paculty by the Paculty by the Paculty by the Paculty after the Paculty by the Paculty by the Paculty by the Paculty after the Paculty by the Paculty by the Paculty after the Paculty by the Paculty after the Paculty by the Paculty after the Pacu (v.) Two representatives of the Board of Intermediate Medical Studies to be appointed from the members of the Faculty by the Faculty after report from the Board in question. (vi.) Four representatives of the Board of Advanced Medical Studies to be appointed from the members of the Faculty by the Faculty after the report from the board in question. (vii.) Six members to be elected from the Faculty by the Faculty, each such member to be nominated by not less than two members of the Faculty. (viii.) The three representatives of the Faculty of Medicine on the Senate. (ix.) All members of the Faculty of Medicine not included in the foregoing categories who are also members of the Senate.

The second report of the committee concerned the various reports of the Boards of Studies which had been referred to The text of this report was circulated to the members of the Faculty of Medicine on Oct. 19th-22nd, 1909.

the Faculty of Medicine on Oct. 19th-2znd, 1909.

Without expressing any definite opinion on the details of the reports of the Boards of Studies, the Faculty consider that, in order to secure coordination among the medical schools and improve the efficiency of medical education in London, it is important that the control by the University over the medical schools be increased.

This can be effected by securing to the University the disposal of funds which it can apply for the maintenance of education and research in the London medical schools.

The Faculty also draw attention to the fact that, unlike many medical schools attached to universities, the medical schools of the London hospitals receive no grant in-aid from the Treasury, and are almost entirely dependent on students' fees.

The Faculty recommend that the report of the special committee appointed by the Faculty in 1905, which report was adopted by the Faculty, should be reaffirmed.

Mr. H. J. Waring moved, and Dr. Norman Moore seconded, a resolution which was adopted unanimously, that this report, as amended, be forwarded to the Senate by authority of those present.

THE NATIONAL LEAGUE FOR PHYSICAL EDUCA-TION AND IMPROVEMENT.—The fourth annual general meeting of the league will be held at the Royal United Service Institution, Whitehall, S.W., on Dec. 9th, at 3.30 P.M., the Right Rev. the Lord Bishop of Ripon in the chair. Tickets may be obtained on application to the secretary of the league, 11, Southampton Row, London, W.C.

THE LONDON COUNTY COUNCIL AND PUBLIC ABATTOIRS.—The public health committee reported to the London County Council on Nov. 30th with reference to a request by the Local Government Board to be furnished with the observations of the Council on a memorial addressed to the Board as to the desirability of establishing public abattoirs in London. The question has been repeatedly postponed by the Council since 1898, when the committee recommended the establishment of public abattoirs. The committee now advised that, having regard to the fact that the Council had no statutory powers to provide public slaughter-houses and to the special circumstances of London and the numerous interests concerned, the Council should inform the Local Government Board that in its opinion a departmental committee should be appointed to inquire into the question of the establishment of public slaughter-houses in London as well as into the question of food inspection generally. recommendation was approved.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Housing and Town Planning Bill.

THE Housing and Town Planning Bill has now reached the final form in which it will receive the Royal Assent. The points of difference between the Lords and the Commons have been compromised and adjusted, and on Thursday, Nov. 25th, the latter, at the instance of the President of the Local Government Board, gave their formal assent to the necessary amendments. Speaking on this occasion Mr. Burns emphasised the importance of the irremoveability of the medical officer of health of a county (except with the consent of the Local Government Board) which the Bill secures. Lord ROBERT CECIL also expressed his satisfaction on this point.

The Oaths Bill.

The House of Commons has assented to the amendments made in the Oaths Bill by the House of Lords. It has since received the Royal

Asylums Officers' Superannuation Bill.

Many amendments were made by the House of Lords in the Asylums Officers' Superannuation Bill. The SPEAKER of the House of Commons ruled that about a third of them were privileged amendments inasmuch as they created a further public charge. However, on the explanation of Sir WILLIAM COLLINS that they were in furtherance of the objects of the Bill, the House waived its privilege, and assent was given to the amendments.

The Finance Bill.

The Marquis of LANSDOWNE'S motion hanging up the Finance Bill "until it has been submitted to the judgment of the country" has been carried by 350 votes to 75 in the House of Lords. The result of this will be a General Election in January.

HOUSE OF COMMONS.

THURSDAY, NOV. 25TH. Discharged Lunatic Seamen.

Discharged Limitic Neamen.

Mr. Flynn asked the Civil Lord of the Admiralty what practice was adopted by the Admiralty authorities in respect to lunatic seamen discharged from the Royal Navy; whether it was the custom to send these men to their relatives or to the workhouses of their native districts; if so, was the practice sanctioned by naval medical officers; and did the Admiralty authorities propose to continue the practice of deducting from the pension or other allowance given to discharged lunatic seamen now maintained in Irish lunatic asylums the capitation grant paid by the State towards their maintenance and transferring the amount of such grant to the relief of the vote for the Admiralty.—Mr. Lamberst replied: The procedure of the Admiralty is governed by the Lunacy Acts, 1890-91, and by the provisions of the Army Act, Section 91, made applicable to the naval service by Section 3 of the Naval Enlistment Act, 1884. Dangerous lunatics are committed to an asylum, those entitled to pensions for life being admitted to the Royal Naval Hospital, Yarmouth, Non-dangerous lunatics are sent to Yarmouth or to the union of the parish to which it appears from the declaration made on entry and

from other information that they are chargeable, unless their relations from other information that they are chargeable, unless their relations or friends are willing to take charge of them and the Admiralty is satisfied that proper care will be taken of them. In the latter case the Admiralty acts on the advice of the naval medical authorities. With regard to the last part of the question, the reduction of the pension by the amount of the grant received by the asylum authorities from the Local Taxation Account in aid of the pensioner's maintenance is made in accordance with the provisions of Section 7. Clause 2, of the Superannuation Act of 1887, and the Admiralty has no option in the matter.

Territorial Medical Officers in London.

Captain FABER asked the Secretary of State for War whether he would state whether there was a senior Territorial medical officer in London suitable to take command of No. 1 London General Hospital.—Mr. HALDANE answered: This general hospital is formed by the staff of St. Bartholomew's Hospital. The senior physician asked that Colonel Harrison, a distinguished medical officer who had been in the Grenadier Guards, should be appointed administrator, and he was accordingly gazetted on Nov. 2nd.

Royal Army (Territorial) Medical Corns Transport.

Sir Samuel Scott asked the Secretary of State for War whether he Sit Sanuel. Scott asked the Secretary of State for war whether he could give any date upon which the re-issue of harness to the Royal Army Medical Corps Transport of the Territorial Army would be completed; and what steps were being taken in the interim to admit of the men receiving the necessary training with wagons.—Mr. HALDANE replied: Orders were issued on Nov. 12th for the re-issue of the harness that had been withdrawn.

The Health of the Troops in Malta.

The Health of the Troops in Multa.

Answering Mr. LUPTON, Mr. HALDANE said: During recent years improvements have been steadily carried out in relation to the drainage of the harbours in Multa. In 1906 a considerable number of the troops were transferred from St. Elim to the new barracks. The Mediterranean Fever Commission, however, obtained no evidence connecting the condition of the harbours with the prevalence of Mediterranean fever amongst the troops. Since the prohibition of the use of goat's milk in barracks and hospitals Mediterranean fever has practically disappeared from amongst the troops. The evidence given in the reports of the Royal Suciety's Mediterranean Fever Commission connecting goat's milk and Mediterranean fever is so strong and the improvement in the health of the troops since the use of goat's milk has been given up is so marked that no responsible Minister who did not wish to be regarded as weak and incompetent would venture to remove the prohibition of the weak and incompetent would venture to remove the prohibition of the use of goat's milk by the garrison.

Hemel Hempstead Union Infirmary.

Mr. Talbot asked the President of the Local Government Board whether his attention had been called to the recent death of a patient in the infirmary of the Hemel Hempstead union, which formed the subject of an inquiry before the coroner; whether he proposed to take any action with regard to the management of that workhouse, especially as regards the treatment of the sick poor; and whether he could hold out any expectation of the issue of a General Order to ensure the appointment of trained nurses in all workhouse infirmaries.—Mr. Burns wrote in reply: My attention has been called to the case referred to. I deeply regret the occurrence and I have fully informed myself with regard to the circumstances connected with it. I am giving consideration to the management of the sick wards of the workhouse in question, and I am in communication with the guardians on the subject. With regard to the last part of the question, I may point out that under the orders at present in force provision is made for the appointment of one or more nurses of experience in every workhouse.

Wednesday, Dec. 187.

WEDNESDAY, DEC. 1ST.

Sleeping Sickness in Nyasaland.

Sleeping Sickness in Nyusuland.

Mr. Rees asked the Under Secretary of State for the Colonies whether an authenticated case of sleeping sickness occurred in the native hospital of the Church of Scotland Mission in Nyasaland last September; and whether he was aware that the existence of other cases was suspected.—Colonel Seely replied: Two natives suffering from sleeping sickness were admitted to the Blantyre Mission Hospital on June 8th and August 14th respectively. The first patient died in July and the second, who came from Portuguese territory, died in September. The natives of Nyasaland are being systematically examined for sleeping sickness. Up to Sept. 30th four cases had been discovered, but there is no reason to suppose that infected persons are numerous in the Protectorate.

Carbon-Monoxide Gas Fatality.

Carbon-Monoxide Gas Fatality.

Mr. George Roberts asked the Secretary of State for the Home Department whether his attention had been directed to the recent case in which a workman was found dead and another unconsclous at the Winnington (Northwich) chemical works; whether these men had been overcome by carbon-monoxide gas; and, if so, whether he would further consider the advisability of scheduling affection by this gas as an dangerous disease under the Workmen's Compensation Act.—Mr. Gladstone replied: I have obtained a report with regard to the circumstances of this case, from which it appeared that the men were suddenly overcome by carbon-monoxide gas while cleaning out a cylinder in a tower used for washing residual gases. The case, therefore, appears to be one, not of disease, but of accident, to which the provisions of the Workman's Compensation Act are already applicable. It was announced at the inquest on behalf of the employers that full compensation would be paid. be paid.

N.B.— A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Rotes, Short Comments, and Answers to Correspondents.

NATIONAL PURE FOOD ASSOCIATION.

A MEETING, convened by the recently formed National Pure Food Association, was held at 20, Hanover square. London, W., on Nov. 30th, under the chairmanship of the President, Mr. F. E. Smith, K.C. M.P., who explained the objects of the association to a small gathering of "pure food" campaigners. In strong contrast with Mr. Smith's guarded statements was the tone of some of the other speakers. Mr. Smith was careful to explain that the majority of traders were above reproach, and that, compared with those shopkeepers to whom it would be repugnant to supply adulterated food, the exceptions were inconsiderable. On the other hand, Canon Horsley left the impression on the audience that the sale of adulterated food was alarmingly prevalent, and he expressed the belief that the reason why the Sale of Food and Drugs Acts was not properly administered in some districts was that too many shopkeepers were members of local authorities. In referring to traders who sell sophisticated food he used the expressions "liars, thieves, and murderers." As not unusually happens when enthusiastic laymen discuss professional subjects, many exaggerated statements were made during the evening, but the exact facts were furnished by Colonel C. E. Cassall and others. Colonel Cassall pointed out that if authoritative standards for foods were set up, these standards would necessarily have to be low, and that by no form of repressive legislation would it be possible to secure a food-supply of high quality. Two resolutions were proposed and adopted. These resolutions urged upon the Government the desirability of appointing a Royal Commission to inquire into the question of food adulteration, with especial reference to the use of chemical preservatives and to the desirability of setting up a food standard of purity by Act of Parliament. The terms of the resolutions were somewhat complicated, and set forth, among other things, that the "recent exposures concerning food frauds afford data whereby the amount yielded may not unreasonably be computed at a minimum of one penny per day per person, which amounts to the colossal sum of £66,000,000 per annum." This sort of calculation serves no purpose.

AN ETHICAL QUESTION.

A CORRESPONDENT Writes :-

A advertises a part of his practice for sale, and is in negotiation with B and C as purchasers. C buys it and a little later B wishes to know if he has a right to start in practice in the same town (population about 120,000), or is he debarred from doing so by having received information confidentially from A

We feel strongly that B should not start in practice in the same town.

MARAT ON MIND AND BODY.

It is pretty generally forgotten that Jean Paul Marat, the notorious revolutionist, attained to considerable eminence as a physician and scientific writer before plunging into the vortex of politics, from which he did not emerge. His earliest and one of his best-known books was published by him in England in 1773, under the title "A Philosophical Essay on Man: Being an Attempt to Investigate the Philosophical Essay on Man: Being an Attempt to Investigate the Principles and Laws of the Reciprocal Influence of the Soul and Body." The book, as Mr. Morse Stephens has pointed out, "shows a wonderful knowledge of English, French, German, Italian, and Spanish philosophers." It is directed against Helvetius, who scoffingly declared in his "L'Esprit" that a knowledge of science was unnecessary for a philosopher. In the "Essay on Man" Marat declared that "Physiology alone can solve the problems of the connexion between soul and body, and proposes the existence of a nervous fluid as the true solution." His work was in fact what would now be called "materialistic." It is curious to find Marat, whom many have regarded as a monster of cruelty during the First whom many have regarded as a monster of cruelty during the First French Revolution, writing, when still a young and polished man of the world and of science, "Observations on the Manner in which Organisation Renders Man Obdurate and Cruel, Compassionate and Humane." If, says Marat, the soul be "united to gross organs, or to fibres too solid or too lax," it "becomes obdurate and inflexible; when united to organs delicate, elastic, and vigorous, it becomes compassionate and tender. Hence pity, although an artificial sentiment, is nevertheless, in every individual, modified by the organisation. The greater the sensibility of man, he may thence be the more humane; and by a very singular consequence, he may thence be the more cruel." A man, for instance, very solicitous for his own wellbeing, will be apt to regard those who threaten it with extreme hatred and will seek their ruin. "Let us therefore conclude, that the more sensible a man is, the more he is obnoxious to hatred, his cruelty is greater, and the more atrocious his character."

Marat was himself a conspicuous instance of the interaction of mind and body. In May, 1792, he returned from England, whither political persecution had driven him, and was compelled to hide in cellars and in sewers, like the characters in Hugo's "Les Misérables." Living the life of a human rat, this once fashionable medical man contracted a horrible skin disease, or developed the later symptoms of lues, and suffered physical agony for some three years, until stabbed by Charlotte Corday in July, 1793, when in his bath. In the bath he wrote the ferocious articles in his paper, the .1mi du Peuple, and here for a time he escaped the worst of his pains; but there can be little doubt that much of his ferocity, his suspicion, and his abnormal hatred of his enemies was due to maddening physical irritation and the knowledge of approaching death.

HEALTH OF THE STRAITS SETTLEMENTS.

ACCORDING to the annual report, just presented to Parliament, of the Governor of the Straits Settlements, Sir John Anderson, G.C.M.G., the present estimated population of the colony is 628,016. The deathrate in 1908 was 43 06 per 1000 of the population, as against 39 07 in 1907. The birth-rate in 1908 was 28 75 per 1000, as compared with 26 11 in 1907. There were 12 deaths from small-pox, 178 from cholera, and 12 from plague. The stringent quarantine regulations and the vigilance of the medical and municipal authorities have hitherto prevented these scourges from finding a permanent home in the colony. Of other important specific diseases beri-beri accounted for 1900 deaths and phthisis for 2988, as against 1626 and 2820 respectively in 1907. In spite of the high death-rate, the climate in the towns and in the country which has long been opened up cannot be considered unhealthy for Europeans, who, if they take ordinary precautions, can, with their higher and more sanitary mode of life, to a great extent avoid the malarial and other tropical fevers and dysentery which attack the Oriental inhabitants of the peninsula. Practically all the hospitals of the colony are under Government management and those maintained on estates are under Government supervision. The number of patients treated in the hospitals in 1908 was 32,805, of whom 974 were Europeans. In 1907 the corresponding numbers were 28,708 and 1193 respectively. Deaths numbered 3869 (62 being Europeans), as against 3688 and 74 in 1907. The rate of mortality was thus 11'8 per cent. of the total treated, as against 12'85 per cent. in the previous year. 417 persons remained in the colonial leper asylums at the end of the year, as compared with 389 on Dec. 31st, 1907. 118 deaths occurred, as against 135.

THE HOME TREATMENT OF TUBERCULOSIS.

At the Tuberculosis Exhibition held last week at the Chelsea Town The Tuberculosis Exhibition held has week at the Cheisea Lown Hall a series of popular lectures have been very well attended by the public. The subject dealt with on Saturday was "The Patient's Part in the Continuation of Sanatorium Treatment at Home." Sir James Crichton-Browne, the chairman, on introducing the lecturer (Mr. Stanley Bates) remarked that there could be no doubt that sanatorium treatment was frequently unjustly discredited from the fact that the patients on leaving, too abruptly resumed their occupations and former mode of life. In his opinion, a period of rigid hygienic discipline was always advisable after the departure of the patient from the sanatorium. It was with this period of transition that the lecturer would deal, recounting his own experiences as a patient. The chairman added that Mr. Bates had the approval of high authority for the open-air shelter he had devised and for the means he advocated for the successful continuance of sanatorium treatment under medical instruction. Mr. Bates, after emphasising the need for such medical supervision and advice, and the necessity of regarding his observations as those of a layman, treated his subject in a practical manner, illustrating his remarks with references to patients discharged from Frimley Sanatorium and with lantern slides demonstrating his own experiences.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Beek.

ROYAL SOCIETY OF MEDICINE, 20, Hanover-square, W.

TUESDAY.

THERAPEUTICAL AND PHARMACOLOGICAL SECTION (Hon. Secretaries—J. Gray Duncanson, H. Charles Cameron): at 4,30 p.m.

Dr. Reginald G. Hann and Dr. R. A. Veale: A Fatal Case of Poisoning by Phosphorus taken as an Abortifacient, with Unusual Subcutaneous Hæmorrhages.

ascusson: on the Therapeutic Value of the Lactic Acid Bacillus, to be opened by Dr. Herschell. Dr. Haberson, Dr. Eyre, Dr. R. Hutchison, Dr. Goodbody, Dr. Vaughan Harley, and Dr. C. W. Miller, will take part.

Pathological Section (Hon. Secretaries—L. S. Dudgeon, C. Bolton) at Cancer Research Laboratory, Middlesex Hospital, W.: at 8.30 p.m.

ommunications:
Mr. Hastings, Mr. MacCormac, and Mr. Woodman: The Histology of Secondary Carcinomatous Nodules treated with Pitchblende (radium).

Mr. J. Bland-Sutton: Osteosarcoma of Breast.
Dr. H. A. Colwell: (1) Catalase; (2) Autolysis of the Tissues of Malignant and Non-malignant Subjects.
Dr. H. Beckton: Altmann's Granules as a Test for Malignancy or

Non-malignancy.

Dr. J. C. Mottram: A New Method of Estimating K and Na in Tissues, with Observations in Malignant and Non-malignant

- Mr. Bryden Glendining: The Spread of Carcinoma by the Miss Helen Chambers: A New Method of Studying Chemiotaxis.
- Demonstrations
- Dr. Lazarus Barlow: Skotographs.

 Mr. Pearce Gould: A Forearm removed for X Ray Dermatitis and Carcinoma.
- Mr. Somerville Hastings: The Effect of Testicular and Ovarian Extracts on the Development of Ascaridean Ova.
 Dr. Beckton: Altmann's Granules in the Embryo.
 Dr. Mottram: On the Existence in Tissues of Substance which Desensitises a Photographic Plate.

WEDNESDAY.

Balneological and Climatological Section (Hon. Secretaries—Septimus Sunderland, F. A. de T. Mouillot): at 5.30 p.m.

Papers: Dr. Clippingdale: The Chiltern Hills. Dr. Mahomed: Atmospheric Electricity.

Neurological Section (Hon. Secretaries—E. Farquhar Buzzard, Wilfred Harris): at 4.30 p.m.

Clinical Meeting:
Cases will be shown illustrative of Syphilis of the Nervous
System (excluding Tabes and G.P.I.).

Dr. James Taylor: (1) Recurrent Left-sided Convulsions, with Transient Motor Aphasia, in a Left-handed Woman; (2) Left Hemiplegia, with Left Third Nerve Paralysis, in a Woman, with Nodes on Forehead and Corneal Opacities.

Dr. Wilfred Harris: Two Cases of Chronic Syphilitic Poliomyelitis of the Upper Extremities.

And other Cases.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION (Hon. Secretaries-William J. Gow, G. F. Blacker): at 7.45 p.m.

Specimens.

Specimens:
Miss L. Garrett Anderson: Adeno-carcinoma of the Ovary.
Mr. J. Barris: A Tumour of the Uterus of Doubtful Nature.
Dr. Walter Tate: (1) A Case of Myxofibroma of the Ovary Removed under Spinal Anæsthesia; (2) Primary Carcinoma of the Fallopian Tube.
Dr. Clifford White: Quadruplets.
Dr. J. Abernethy Willett: Quadruplets.
Mr. H. J. Paterson: (1) Double Tuberculous Pyosalpinx; (2) A New Apparatus for Continuous Proctoclysis.
Dr. H. R. Spencer: Cæsarcan Section and Hyterectomy for Fibroids with Degeneration of Uterine Muscle.
Short Communications:
Dr. Philip D. Turner: Abdominal Hysterectomy 63 Hours after Labour for a Necrosed and Suppurating Subperitoneal Fibroid.
Dr. A. H. Lewers: Note on a Case of Cystic Tumour of the

Dr. A. H. Lewers: Note on a Case of Cystic Tumour of the Right Broad Ligament springing from the Uterus and apparently Developed from Gärtner's Duct.

CLINICAL SECTION (Hon. Secretaries: H. D. Rolleston, M.D., Albert Carless, M.S.): at 8.30 P.M.

- Mr. Herbert J. Paterson: Case of Gumma of the Breast Simulating Malignant Disease.
 Mr. John R. Lunn: A Case of Acromegaly.
 Dr. Mine (introduced by Mr. Carless): (1) An Acromegalic Giant: (2) Two Cases of Achondroplasis.
 Dr. McMullen (introduced by Dr. Rolleston): A Case of Adiposis Doloross

Dolorosa.

Dr. Herringham: (1) A Case of Aneurysm (2) in a Young Woman resembling that exhibited by Dr. McNaity last meeting: (2) Rheumatoid Arthritis in a Boy with Albuminuria and Enlargement of Glands, Liver, and Spleen.

Mr. A. Carleas: Removal of Large Stone (856 grains) from the Ureter.

Mr. W. G. Spencer: Case of Trephining for General Epilepsy (3

Years after).

Mr. J. D. Malcolm: Case of Cholecyst-duodenostomy for Acute

Emaciation.

Dr. Poynton: Congenital Œdema in Mother and Child associated with Cardiac Defect.

UNITED SERVICES MEDICAL SOCIETY, Royal Army Medical College, Millbank, S.W.

WEDNESDAY.—8.30 P.M., Fleet-Surgeon F. H. A. Clayton, R.N.: Notes on Seven-day Fever of Eastern Ports—its Occurrence in the Navy and its Relationship to Dengue.

HUNTERIAN SOCIETY, London Institution, Finsbury-circus, E.C. WEDNESDAY.—8 30 P.M., Mr. B. H. Fenwick: Surgical Aspects o Kidney Discase.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM, Chandos-street, Cavendish-square, W

Chandos-street, Cavendish-square, W.
 THURSDAY.—8 P.M., Card Specimens by Mr. S. Stephenson, Mr. N. B.
Harman, and others. Delaration of the Poll of the Society re
Amalgamation. 8.30 P.M., Mr. R. W. Doyne: (1) Description of
a Form of Conjunctivitis; (2) A Note on Family Chorolditis
(with patient); (3) A Note on Myopic Degeneration of the Lens
(with patient); (4) Note on a Form of Iritis.—Mr. M. S. Mayou:
Congenital Sarcoma of the Orbit.—Mr. A. P. L. Wells and Mr.
M. S. Mayou: A Round celled Sarcoma of the Lacrymal Gland.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY, Board Room of the Great Northern Central Hospital, Holloway-road, N. THURSDAY. - Mr. E. H. Shaw: Pathological Demonstration.

HARVEIAN SOCIETY OF LONDON, Stafford Rooms, Titchborne street, Edgware-road, W.

Thursday. -8.30 P.M., Dr. W. H. Dolamore: Pyorrhica Alveolaris. -Dr. A. Fleming: The Specific Treatment by Inoculation of Infective Conditions of the Mouth.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c. ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

FRIDAY.—5 P.M., Mr. F. R. Cross: The Brain Structures concerned in Vision and the Visual Field. (Bradshaw Lecture)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

Chemics street, W.C.

Monday.—4 p.M., Dr. W. Evans: Clinique (Skin). 5.15 p.M.,
Lecture:—Dr. D. Ferrier: The Etiology and Treatment of
Tabes.

Tussday.—4 p.M., Dr. L. Guthrie: Clinique (Medical). 5.15 p.M.,
Lecture:—Mr. A. Carless: Some Fractures about the Wrist
Joint (with lantern illustrations).

Weddigay.—4 p.M., Mr. E. Corner: Clinique (Surgical). 5.15 p.M.,
Lecture:—Dr. G. Pernet.

Thursday.—4 p.M., Sir Jonathan Hutchinson: Clinique (Surgical).
5.15 p.M., Lecture:—Prof. W. Thorburn (Manchester): Some
Points in the Surgery of the Billary Passages.

FRIDAY.—4 p.M., Mr. V. Cargill: Clinique (Bye). 5.15 p.M.,
Dr. E F. Bashford: Some Result of the Comparative Biological
and Experimental Study of Cancer.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmithroad, W.

M. Monday.—10 a.m., Lecture:—Surgical Registrar: Demonstration of Cases in Wards.
 2 p.m., Medical and Surgical Clinics.
 X Rays.
 Mr. Dunn: Diseases of the Eyes.
 2.30 p.m., Operations.
 5 p.m., Lecture:—Mr. Bidwell: Practical Surgery.
 TUESDAY.—10 a.m., Dr. Moullin: Gynscological Operations.
 12.15 p.m., Lecture:—Dr. Pritchard: Practical Medicine.
 2 p.m., Medical and Surgical Clinics.
 X Rays.
 Dr. Davis: Diseases of the Throat, Nose, and Har.
 2.30 p.m., Operations.
 Dr. Abraham: Diseases of the Skin.
 5 p.m., Lecture:—Dr.
 R. Jones: The Treatment of Mental Cases by the General Practitioner.

Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. R. Jones: The Treatment of Mental Cases by the General Practitioner.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Diseases of the Throat, Nose, and Ear. 12.15 P.M., Lecture:—Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. B. Harman: Diseases of the Byes. 2.30 P.M., Operations. Dr. Robinson: Diseases of Women. 5 P.M., Lecture:—Dr. Low: Prophylaxis of Tropical Diseases.

Diseases
THURSDAY.—10 A.M., Lecture:—Surgical Registrar: Demonstration
of Cases in Wards. 12 noon, Pathological Demonstration:—
Dr. Bernstein. 2 P.M., Medical and Surgical Clinics. X Rays.
Mr. Dunn: Diseases of the Ryes. 2.30 P.M., Operations. 5 P.M.,
Lecture:—Mr. R. Lloyd: Amesthetics.
FRIDAY.—10 A.M., Dr. Moullin: Gynacological Operations. Medical
Registrar: Demonstration of Cases in the Wards. 2 P.M.,
Medical and Surgical Clinics. X Rays. Dr. Davis: Diseases of
the Throat, Nose, and Bar. 2.30 P.M., Operations. Dr. Abraham:
Diseases of the Skin. 5 P.M., Lecture:—Dr. S. Taylor: Pneumonia.

monia.

Saturday.—10 A.M., Dr. Saunders: Diseases of Children. Mr. B.

Harman: Diseases of the Eyes. Dr. Davis: Diseases of the
Throat, Nose, and Ear. 12.15 p.m., Lecture:—Dr. G. Stewart:
Practical Medicine. 2 p.m., Medical and Surgical Clinics.

X Rays. 2.30 p.m., Operations.

Fractical medicine. P.M., Medical and Surgical Clinics. X Rays. 230 P.M., Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

Monday.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery.
3.15 P.M., Sir Dyce Duckworth: Medicine. 4 P.M., Mr. R.
Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Kar and Throat.

TUESDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Wells: Medicine.
3.15 P.M., Mr. Carless: Surgery. 4 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 2.15 P.M., Special Lecture:—Dr. R. Wells: Some Points in Cardiac Pathology.

WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Bye.

THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. 4 P.M., Dr. Sale-Barker: Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Rar and Throat. 2.30 P.M.. Dr. G. Rankin: Paralysis in Children in some of its Clinical Aspects.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. Saturday.—2 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. Saturday.—2 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of

10 a.M., Surgical and Medical. 11 a.M., Bye.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed emolusively "To THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTI-FICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication. We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager.

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES. TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

Until the end of the present year copies sent by post will be charged at the rate of $7 \pm d$. inland and 8d. abroad.

Commencing with the issue of Jan. 1st, 1910, the rates of subscriptions, post free from THE LANCET Offices, will be :-

FOR THE UNITED KINGDOM.

One Year £1 1 0
Six Months 0 12 6
Three Months 0 6 6

Three Months 0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs. 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA-Messrs. WILLIAM WOOD AND Co., 51, Fifth Avenue, New York, U.S.A.

ON

A RENEWED RESEARCH ON THE SUBJECT OF ACUTE OVERSTRAINING OF THE HEART.

Delivered at the Opening of the Winter Session of the West London Post-Graduate College on Oct. 11th, 1909,

By Professor SCHOTT, M.D.,

NAUHEIM.

MY LORD DUKE, LADIES, AND GENTLEMEN,—Before proceeding to read you my paper on acute overstraining of the heart, allow me to express my sincere thanks to the distinguished faculty of the West London Post-Graduate Medical College for the great honour they have conferred upon me by their kind invitation to deliver this address this evening.

While in the first half of the last century the valvular affections of the heart, with their train of symptoms, received the almost exclusive attention of the medical world, the chronic diseases of the cardiac muscle, and above all its functional disturbances, became later on the subject of much closer investigation. The organic changes in the heart muscle were in many cases not difficult to determine, either macroscopically or more especially under the microscope, but it was otherwise in the case of those disturbances which we denote as purely functional. it was here that—as must be familiar to everybody, especially in this country—the pioneer work of Peacock, and his observations on Cornish miners, acquainted us with the true character of cardiac overstraining. From that time forward this chapter of cardiac pathology has never ceased to command the sustained and watchful interest of the medical world. Furthermore, the great development of athletic sports which has taken place during the last two decades, especially here in England, has greatly increased the number of cases of cardiac overstraining which in consequence came under medical observation. observations of Peacock were confirmed later on by the investigations of Myers, Clifford Allbutt, Da Costa, Johann Seitz, Münzinger, and others. Nevertheless, knowledge of the true facts concerning overstrain of the heart could only win its way very slowly, for many declared themselves to be definitely opposed to the new teaching, whilst others spoke with very great caution and made known to the world their manifold doubts on the question, as, for instance, von Schroetter, E. Seitz, and Strümpel. It was the investigations of Levden and Fraentzel which once more gave a fresh impetus to the researches on this subject.

I myself have reported in the year 1890 at the Ninth Congress of Internal Medicine in Vienna a series of experiments which I made in order to determine whether bodily overstraining could produce alterations in a healthy heart, and also to determine eventually the nature of such changes. For this purpose I selected young, robust individuals, from 14 to 32 years of age, whose previous state of health, as well as the physical examination to which I subjected them, showed them to be free from any anomaly of the heart whatever. I made two of them wrestle with one another, resisting or lifting each other, until a high degree of dyspnea had been produced by the previously increased muscular straining. In a second series of experiments, in order to increase the dyspnœa and render the cardiac action still more difficult, I fitted a leather belt close under the costal arch of the subjects and made them wrestle while thus hampered. In both series of experiments I actually did find that, when such severe physical overstrain leads to dyspnœa, the heart undergoes a greater or lesser amount of dilatation. This I designated as acute cardiac dilatation, which, of course, is to be regarded as a temporarily abnormal, but not as a pathological, condition. This, as I mentioned at the time, is evidenced by the fact that in healthy, robust persons such an artificially produced cadiac dilatation can generally recede entirely within a very short time, often in one or two minutes. I must add

¹ See the Transactions of the Ninth Congress for Internal Medicine in Vienna, 1890. No. 4502. that in my first experiment the cardiac dilatation was determined, not only by a colleague and with ordinary percussion of the absolute cardiac dulness, but also by myself, and according to the method of my brother, August Schott, consisting in the percussion of the total heart limits with lateral limitation. The experiments I made with this method on animals, as well as the investigations conducted by me later on in the Berlin Maison de Santé on the human cadaver, have shown the possibility of determining the anatomical limits of the heart by means of this kind of percussion.

When, subsequently, the heart and its movements were made evident to the eye by means of the Roentgen rays, I found all the observations I had made by percussion fully confirmed, not only by the determination of the heart limits on the barium platino-cyanide screen, but by Roentgen photographs as well. It is especially these that show the expansion of the left ventricle, and notably with a depressed diaphragm. In order to find the true measures I rendered the nipples visible by means of small pieces of thin sheet lead, while by fixing the body of the subject under examination with straps around the head and shoulders, also by very exact drawings of the outlines of the feet on the floor, I had taken care to place the man always accurately in the same position relative to the apparatus, before wrestling and after. I had marked the nipples exactly by making dots on gelatine strips, and using these as reference marks I could verify their being again in the same place at the second examination. Naturally, only such experiments were regarded as conclusive in which all these precautions were rigidly adhered to. It was also the purpose of the above-described experiments to show that by a succession of bodily over-exertions the clinical picture of chronic cardiac overstraining may be developed. For, as I mentioned at the time, chronic overstraining of the heart is to be regarded as the result of a repetition of excessive muscular efforts. In order to illustrate this point I also added to my article the description of a few cases, and I found my views to coincide with the observations of Peacock, Clifford Allbutt, Fraentzel, Leyden, and several others.

Not only my experimental researches, but also my statements concerning especially such cardiac anomalies as follow the indulgence in excessive athletic sports, soon found confirmation in the works of Mendelsohn, and more particularly in the enlargements of the heart found in bicyclists by Albu and in ski runners by Henschen. Indeed, it seemed for a while as if chronic cardiac overstraining, solely produced by the cumulative effect of repeated and abnormally strong muscular efforts, was to be incorporated as a picture sus generis of cardiac pathology. This, however, did not last long. The former objection was heard again, that no heart can undergo permanent dilatation or hypertrophy through severe muscular overstrain unless previously altered, either in structure or in function. In this connexion doubts were also entertained whether, in my experimental investigations on acute overstraining of the heart, the subjects of the experiments had been entirely normal. These doubts were especially accentuated by the orthodiagraphic examinations of Moritz, Aug. Hoffmann, and de la Camp. Not only do these experimenters claim to have found in the course of their investigations no cardiac changes at all, or at best very insignificant ones, but they even state that best very magnificant ones, but they even state that they observed cases where a diminution in size of the heart had actually occurred. About the same time, as we shall see further on, others confirmed, on the strength of their own researches, the occurrence of acute cardiac dilatation. tion following acute overstrain in previously healthy individuals. Owing to material causes it was only in the year past that I was able to undertake further experiments on the subject which interests us here, and it is upon these, as well as upon other correlated experiences gained, that I wish to report here as briefly as possible. The first question to be considered is whether it is possible for a healthy heart muscle to hypertrophy from an excess of work.

If this question be answered in the affirmative, the question would also be answered whether an excess of work will cause a heart muscle to dilate, since nowadays there is hardly a divergence of opinion regarding the theory that dilatation is the primary, hypertrophy the secondary lesion. The old view of Fraentzel to the contrary may now be considered as controverted, while that of Thurn, Jürgensen, J.

A 4

Bauer, and others is, with few exceptions, generally considered to be correct. It lies in the very nature of the case and my brother was the first to call attention to the fact-that in such conditions we have only to deal with an accumulation of blood in the cardiac cavities—in other words, with a passive, congestive dilatation, as opposed to a dilatation by compensation. And now the fine experiments of Külbs on young dogs working a long time on the endless inclined plane have revealed that cardiac hypertrophy due to work does occur, without arterio-sclerosis, without kidney affections, even without increase in size of other parts of the muscular system. Külbs communicates the results of the post-mortem examination of the hearts of such dogs as follows: "Through physical work we can succeed in bringing about, in young dogs of the same litter, of the same sex, and approximately of the same weight, a fairly considerable increase of weight of the heart, both absolute and relative. The proportion of heart to bodily weight changes in this sense, that the working dog acquires a cardiac weight approaching that of the roe-deer, whereas the dog kept for verification and comparison of results showed the proportional weights to be those of the ox."

It is thus physiologically established that simple performance of labour can lead to hypertrophy of the heart. But in men also it has been proved beyond a doubt that there is such a thing as pure, simple cardiac hypertrophy. The exaggerated pursuit of athletic sport, which during the last 20 years has been constantly on the increase, has confirmed all the observations reported in my first publication, and one may find a large number of communications concerning cases where it was simply the physical overstraining due to excessive indulgence in athletic sports that impaired the hitherto healthy heart and led to chronic cardiac overstrain, even in youths who had not suffered from previous maladies nor indulged in the inordinate use of alcohol, tobacco, coffee or tea. This is shown in numerous examples, which can be found in the extensive literature we already have on this subject, in very exact clinical histories as well as in the increased size of the heart found by means of the most diverse methods of percussion, also with the Roentgen rays, including the orthodiagraphic process. I need only here make a passing reference to the fact that sudden strong emotion, fright, or shock, are liable to produce very injurious effects on the heart, and medical men have ample opportunity of observing how prolonged anxiety or mental overstrain often impair the muscles and nerves of the heart. Von Frey in his physiological work very correctly points out that one finds dilatation with cardiac hypertrophy as the result of continued physical overstrain in persons whose hearts had not been subjected to any other noxious influences. And it is just exactly to this fact that I should like to call especial attention. All the former allegations regarding chronic cardiac overstrain having thus been confirmed, the only question requiring further consideration is, whether severe bodily overstrain is capable of exercising a direct effect upon the heart—in other words, whether abnormally severe muscular strain can bring about acute cardiac dilatation.

First of all, I should here like to meet the objection that my cases were persons whose hearts were abnormal, debilitated, or suffering from functional alterations. I experimented on 14 robust youths and young men, from 14 to 34 years of age, and with many of them I frequently repeated the experiments. I have kept most of them under supervision for many years, and to the present day their hearts have remained healthy without exception. As before mentioned, Mendelsohn, Albu, Henschen, and many others have recently confirmed the facts which I had established by percussion. Once more I must premise that the results I had obtained with percussion were corroborated by my radiograms in 1897. Not only did I find a cardiac dilatation, but also a change of form of the heart, which was oval before the experiments, whereas after the wrestling the dilated heart had acquired a more circular form, this with the diaphragm forced downwards. The left cardiac half, which did not reach the nipple line before, extended beyond it ufter the overstrain. The change of form as such is a fact. There might at most be a difference in the elongation of the transverse diameter due to shadow projection, but this cannot be of consequence, since by proper selection of the time of exposure, the person under examination being in the same position, the heart lies close to the

anterior thoracic wall, so that really only the thickness of the chest wall would have to be considered. And now the question arose whether, and to what extent, orthodiagraphic examinations give us better results.

It is not to be doubted that the discovery of orthodiagraphy by Moritz means a progress in the examination and observation of the interior of the body, this being especially the case where it is a question of determining the size of organs at rest or of foreign bodies within the organism. But it is a different matter when it comes to the determination of the size of organs in motion, of which one wishes to make comparative observations at different times. Not only does this apply to the heart but to other organs as well, such, for instance, as the stomach or the intestines while in motion, &c. For we should not forget that every orthodiagram we obtain is the orthogonal, therefore the vertical projection of the greatest extension in one plane. This plane is invariably the same in the resting immoveable body, and therefore in this way we always obtain the same exact size of this body. It is quite different, however, with organs whose position changes more or less like the beating heart. And we shall see that it is exactly these movements of the heart that have to be considered in our experiments. In his extensive work on the subject Guttmann has already pointed out that with orthodiagraphy rotation of the body or changed position of the individual could in repeated delineations or drawings of the cardiac boundaries in different planes lead to differences of from 1 to 2 centimetres and more. Excepting a paper read by Hoffmann in a former congress, I nowhere find any indication that in the experiments made on men or animals the same attitude and position had actually been maintained during the orthodiagraphic examinations made at different times. This repeated use of the same canvas frame does not of itself offer any guarantee of an identity of position. Attempts have been made of late to obtain photographs of the heart with the shortest possible exposure, even in a fraction of a second, and also with the kinematograph. Apart from the fact that the resulting pictures are often wanting in clearness we never know positively in which phase of the heart cycle such photographs were made.

Quite recently, in the course of my work at Nauheim, the two following cases, amongst others, have come under my notice which exactly illustrate my theme. The first case is that of a medical colleague, aged 38 years, whose roentgenogram had been taken by medical men experienced in taking orthodiagrams, and these skiagrams had shown an enlarged heart. The dilated stomach had displaced the heart outwards and upwards. As soon as normal conditions of the digestion were restored the size of the heart was found by percussion to be normal and there remained, without any other abnormality whatsoever, only a simple neurosis of the heart which suitable treatment by means of baths, exercises with resis:ance and massage, speedily improved. The second case is that of a Russian lady, aged 44 years, who has for several years had myocarditis on a basis of diabetes, with the heart dilated to the right and to the left. Both the mitral and the aortic valves had systolic murmurs. In addition there were pronounced symptoms of angina pectoris; yet in spite of all this the orthodiagram taken in Berlin, as also the electrocardiogram showed absolutely normal conditions.

I have already on former occasions called attention to the fact that in order to avoid errors it was necessary to resort to the use of exact marks on the persons to be examined, and in certain cases to fixations that do not interfere with the respiration. It is exactly this which is shown in the heart silhouettes in de la Camp's work, and which were made according to the rules laid down by Moritz. Not only does, as de la Camp states, a changed location of the diaphragm and increased thoracic circumference after wrestling take place, nay, the subject under examination, after the experiment, has actually taken an entirely different position relative to the apparatus. This is clearly evident from the fact that the position of both nipples, relative to a hypothetical horizontal plane, is different before and after the wrestling, this difference allowing a fourfold decrease in size of the heart silhouette amounting to 14 centimetres. In other words, the second results were obtained in an entirely different plane from the first ones, and therefore, even for this reason, they are not to be considered as conclusive. The drawings published by Aug. Hoffmann cannot be accurately judged of, since neither the right nipple nor the location of the diaphragm is depicted in them. After all that has been said, it is hardly necessary to maintain that in view of the possibilities of such great sources of error we are still far from being able to determine the superficies of the heart within one single square centimetre, or its contents in a quarter, a half, or in a whole cubic centimetre. But, as we shall see further on, the possibility of other sources of error will also have to be considered.

A number of further observations have been reported meanwhile by other authors, and these are likely to throw more light on the question of overstraining of the heart. According to the orthodiagraphic examinations by the three investigators mentioned, it appeared as if great interferences with the cardiac functions, changes which, in his experiments on dogs, de la Camp produced artificially in the cardiac valves as well as in the heart's muscular apparatus, had no immediate deleterious effect. And yet the observation of such changes in men should already lead to misgivings, for great dilatation follows acute valvular inflammation. To give a few examples. Beck in his work "Touring and the Heart" reports on 31 young men, in 28 of whom he had occasion to observe the immediate effect of mountainclimbing. We are, above all, interested in his statement that there had been no previous illnesses and that mountainclimbing, which simply produced palpitation and shortness of breath, was followed not only by cardiac symptoms but also immediate dilatation, which he was able to demonstrate by percussion, in one case even by radioscopy. He saw, just as I did, such dilatations disappear in a very short time, often after a few minutes, and he shares my opinion that it is only a matter of over-accumulation of blood within the heart cavities. Beck reports other cases in which the dilatation persisted for a longer time, though in the healthy heart never longer than until the following day. But he also saw cases where, solely through frequently repeated mountain climbing, in persons that otherwise had always enjoyed perfect health, the picture of myocarditis as well as that of mitral insufficiency developed itself. Staehelin, in his observations on Swiss recruits, also pointed out that mountain climbing may lead to acute dilatation of the heart in previously healthy young men, while Düms shows how, simply on account of the severer strain to which soldiers are subjected nowadays, the number of cardiac affections is on the increase in the armies of the different countries. Beyer attributes this evil to the ever-increasing indulgence in the sport of bicycling.

Two years ago Baldes, Heichelheim, and Metzger reported the observations they had made on a number of young men, otherwise in excellent health, after a march of 100 kilometres (60 miles) in one day. In a relatively large percentage of the examinations, by means of percussion of the absolute heart limits, they found dilatation. It is especially to this work that I shall have occasion to revert again. The number of observa-tions on the influence of bicycling on the heart is especially large, and the deleterious effect of this sport is confirmed by nearly all of them. This is particularly evidenced in racing, where heart troubles have been observed in relatively large numbers, also in cases where no other injurious factor was present. But in opposition to these observations we again have others, in which, even after very strenuous physical labour, no enlargement of the heart could be demonstrated, whether by percussion or by radioscopy. I only refer here, among others, to the investigations of Pfeiffer, published a few months ago, which he conducted on men, partly after protracted marches, partly after bicycling tours. In this category also belong the observations of Schieffer, to which I shall shortly revert. But the objections are by no means exhausted herewith. Even diminution in size of the heart after overstrain was found by means of orthodiagraphic examinations, such, moreover, as could not possibly be attributed to changes of position of the disphragm-for instance, the examination made on swimmers by Kienböck, Selig, and Beck, and which led to the risky theory that the heart was relieved by the increasing flow of blood to the abdomen.

This conflict of opinion grows in importance if we consider the following facts: Dr. Baldes, Dr. Heichelheim, and Dr. Metzger kindly allowed me to avail myself here of the results of their unpublished experiments. These gentlemen last year determined the heart limits on healthy persons, ortho-diagraphically, before and again after a march of 100 kilometres in one day. Moreover, these orthodiagrams were

made with the diaphragm in the same position, partly by an expert official of the United Electrotechnical Institute of Frankfort o/M., Aschaffenburg, and partly by Dr. Baldes, who for two years almost daily made radiograms with Rieder in Munich. And now, instead of the enlargement of the heart formerly made apparent by percussion, they found a reduction in size. The copies of their orthodiagrams, which you see here, show very changing pictures. Sometimes we notice an enlargement of the right cardiac half with a reduction in size of the left half, then again the reverse is the case. But most striking above all is the great difference of form in the heart before and after the march. Particularly instructive is the case of a man who had made a very quick run of several hundred metres and had been orthodiagraphed while labouring with dyspnœa. The enlargement of the right half of the heart amounts here to 1 centimetre. On the other hand, the left half not only shows you a transverse diameter reduced by 3 centimetres, but the totally changed and flattened form makes it evident that the orthodiagram of this heart was taken in an entirely different plane after the run than before. The difference in position of the nipples, relative to each other, in the pictures taken before and after the march, argues in favour of this.2 Like those of Hoffmann, all these orthodiagrams were made while the person under examination was in the erect position.

Last year a paper was published by Dietlen and Moritz, according to which they also found smaller hearts after bicycling. This paper exactly proves that it is by no means sufficient to register the results of orthodiagraphic examinations; also that orthodiagraphy of the quickly beating heart is still far removed from constituting an unobjectionable method for the determination of its size. Disregarding the fact that in these examinations by Dietlen and Moritz it is not conclusively proved that the cardiac diameter obtained before and after bicycling represent identical cardiac planes, the cases described do not at all come under the head of genuine acute overstraining of the heart such as I produced in my experiments. As evidenced by the communications themselves of both named authors, their subjects of experiments did not have any albuminuria or apparent palpitation as found by other authors, neither did any dyspnœa develop itself during the entire trip. Judging from this, there may have been a straining involving a quicker pulse, also great fatigue, but a real overstrain was out of the ques-And yet this is of capital importance.

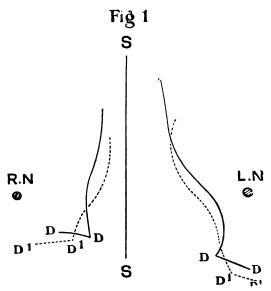

Schieffer, who works in Moritz's clinic, did not, with orthodiagraphy, find any change in the heart whatever immediately after bicycling. Regarding the degree to which the straining was carried, whether or not to the extent of dyspnœa, he fails to impart any information. So that here also there is no agreement between the facts as found and the orthodiagraphic examinations already mentioned. Yet this ought to be the case, were it not that, so far as the beating heart is concerned, orthodiagraphy shares with other methods of examination the disadvantage of inherent sources of error.3

Last autumn, and before I had any knowledge of the investigations above mentioned, I began to verify orthodiagraphically the results of my former experiments on acute overstraining of the heart. Again I had the wrestling and resistance exercises performed by men in absolute health, of unobjectionable health record, whose hearts exhibited normal limits and normal functions. The dispositions were exactly the same as in my former investigations. Measurements and drawings were taken only after excessive dyspnœa. profuse perspiration, palpitation, &c., had manifested themselves. Examinations of the blood pressure and sphygmographic drawings were dispensed with, their results being sufficiently known. The radiograms were obtained in St. Mary's Hospital in Frankfort o/M., partly by the director of the hospital's Roentgen cabinet, Sanitätsrat Dr. Schmidt, partly by Mr. Dessauer, director of the United Electrotechnical Institute of Frankfort o/M., Aschaffenburg.

² Dr. Baldes, whom I only saw in this connexion after these lines

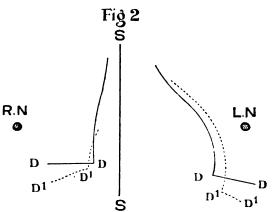

³ Dr. Baldes, whom I only saw in this connexion after these lines were written, remarked to me that he also had been struck by this change of mammiliary positions, this being one of the reasons why the three above-named authors could not decide to publish their results, preferring to make further experiments.
³ A few months ago Schieffer added two more publications to his former paper, also pertaining to this subject. The orthodiagrams, which are intended to show the influence of the different occupations and of military service on the size of the heart, were made exactly like those of Moritz and his pupils, as described above, thereby failing to offer any guarantee as to the reliability of the results obtained.

were made with Dessauer's trochoscope-orthodiagraph, it being claimed that this apparatus furnishes the most reliable results. I had made the wrestler's nipples apparent by pasting on them small pieces of thin sheet lead, and the middle thoracic line by a leaden wire fixed to the chest. The heart's limits were always determined during the condition of maximum diastole and lowest position of diaphragm by means of the well-known perforated screen. The dotting appliance was always exactly vertical over the anticathode of the tubes. In some instances the heart limits were traced directly on the man's thoracic integument, and in others on a horizontal drawing plane, adapted close to the thorax by

s designates the sternal line, RN and LN the right and left nipple, D and D¹ the location of the diaphragm. The continuous lines mark the cardiac outlines before, the dotted lines after, wrestling.

means of a holder. But even with such a perfected apparatus pictures are obtained that differ very much, this being due to several circumstances. It often, for instance, takes a long time before the person to be examined succeeds in reassuming accurately the same attitude in the horizontal position. Besides, it is very difficult for most people to lie quietly with great dyspnœa. Rotations of the entire body are especially apt to set in, which is, however, immediately made

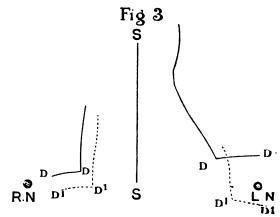

The continuous line indicates the limits of the heart after five minutes' wrestling, the dotted line after ten minutes.

manifest by the positions relative to each other of the marked nipples and sternal line. Or the heart, which in this position is strongly pressed upwards by the diaphragm, rotates considerably on its longitudinal axis. In addition to this, as I have shown in my first work on this subject, it happens that the lungs, being over-inflated through the dyspnæa, compress the heart more or less forcibly from both sides, diminishing its power of action, even displacing the greatest

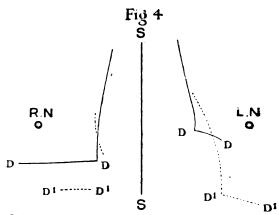

transverse diameter into another plane, unless the disappearance of this artificially produced pulmonary inflation be awaited.

All these elements have to be considered when we wish to obtain pictures susceptible of being mutually compared. I have kept accounts of all these points in my experiments and I now proceed to show you first two orthodiagrams taken by Director Dessauer. In the first one of these (Fig. 1) you see the heart exactly in a phase where, in stormy jerks, it is making powerful movements about its longitudinal axis. After about five minutes' wrestling the heart appears smaller in all its diameters. And in the second orthodiagram (Fig. 2)

Orthodiagram after a first bout of wrestling. The continuous lines mark the cardiac outlines before, the dotted lines after, wrestling.

you see the same heart after five more minutes' wrestling. Although it took a relatively long time to obtain these second outlines, the heart with diaphragm depressed appears manifestly extended to the left. The subject under examination was an absolutely healthy cabinet maker, 34 years of age. The frequency of the pulse had increased from 68 to 116 per minute, respiration from 14 to 28. The orthodiagrams were made on the drawing plane. In most of the experiments I also took notice of the apex beat, except where this was hidden by the costal arch, and after the wrestling I noted an outward and downward displacement. And what I should like to lay especial stress on here is that, with a careful examination, it is by no means so difficult, as claimed, to palpate the left lower limit of the heart muscle in the vicinity of its apex. When the index finger is held perpendicularly

Orthodiagram after a second bout of wrestling. The continuous lines mark the cardiac outlines before the wrestling was resumed, the dotted lines after the end of the wrestling.

to the heart muscle and pressed deeply into the costal interstices, the heart's impact may be felt very plainly, and this motion of the heart as such may be clearly differentiated from the concussion of the thoracic wall.

And here we have two orthodiagrams made by Sanitätsrat Schmidt. They belong to a robust, healthy man of 32, who had never used alcohol, tobacco, &c., in excess. The orthodiagram made after the first wrestling (Fig. 3) shows, even

with deeply depressed diaphragm, the heart forced out of position and in such a manner that the right cardiac half appears to have become smaller, the left, on the other hand, enlarged. And now we take the same man after a few minutes' more wrestling (Fig. 4). Here, with strong dyspnea, profuse perspiration, with an increase of pulsation from 70 to 123-125 and of respiration from 12-13 to 30-32, the picture is as follows: The right cardiac half, which was taken last, shows no change of transverse diameter with moderately depressed diaphragm; on the other hand, the left ventricle after 14 minutes of severe wrestling, naturally performed with several interruptions, has become enlarged 3 centimetres, this with a 5½ centimetre downward displacement of the diaphragm. Altogether a very considerable increase of the transverse diameter of the entire heart, as I have already described it in my first publication.

And now, before closing, I should like in a few words to revert to the question as to what might be the causes that led the several experimenters to such different results regarding the dimensions of the heart in cases of acute overstraining. First of all, we have to consider the circumstance that the determination of the cardiac dimensions may have been made under very different conditions. One investigator, for instance, may have examined during the period of pulmonary inflation; another one, perhaps, after the heart's dilatation had already diminished; while a third one may have determined the maximum cardiac extension while the heart muscle was in the state of greatest relaxation. Of course, it is evident that anyone who did not take part cannot render a reliable verdict on the correctness of the several results of percussion. True, the observations, as well as the nature of the experiments themselves, often differ so much that it is difficult to compare them with each other. To illustrate: Zuntz and Schumberg examined soldiers who had climbed high mountains, laden with accourrements, until difficulty of breathing ensued, and found, while simultaneously testing the inferior pulmonary limits, dilatations in the transverse cardiac diameter amounting to 2 to 3 centimetres, which results Staehelin confirmed. How different the result in Altschul's cases, of which he himself was the first subject of experiment. Namely, after he had bicycled a considerable time on a bad road against a strong head wind I noted-and so did he—a marked cardiac dilatation. On the other hand, he himself, a trained tourist, hardly found any cardiac changes at all in himself or in other trained tourists after a also not troubled with any particular difficulty of breathing. Again, we have the very opposite in the results arrived at by Beck, the men he experimented upon having scaled steep mountains until dyspnea set in. And just compare Pfeiffer's results of his experiments on the effects of protracted marches with those of Baldes, Heichelheim, and Metzger, also those obtained on bicyclists by Pfeiffer with those of Albu.

The cause of the divergence between the experimental results can be traced without any great difficulty, for according to the physiological researches of later years the heart is constructed in such a manner as to represent the most perfect motor with which we are so far acquainted, so that it is capable of answering to the smallest stimulus with a maximum development of power. Moreover, it possesses the faculty to adapt itself to changed demands. Thus, for instance, the dog's heart is capable of taking in six times its normal quantity of blood and yet the left ventricle succeeds in overcoming this amount and contracting again completely. Certainly the heart's work increases enormously in overcoming such obstacles, and the increased intra-cardiac pressure must also be taken into account. But it is a well-known physiological fact that the dog, as far as the heart is concerned, can be subjected without detriment to considerably greater and longer hardships than the human organism, although fortunately the latter also possesses in its cardiac muscular apparatus and in its vascular system all kinds of temporary compensatory arrangements. And to these compensatory powers it is due, as I particularly stated in my first report, that the limits of over-expansion of the healthy heart may lie far apart in the muscularly strong individual. At the same time we see, nevertheless, that the qualities of the heart as a muscle manifest themselves, and to these also belong laxity and expansion as a consequence of excessive strains.

My Lord Duke, Ladies, and Gentlemen, I am firmly convinced that every physician, especially here in England, who has the opportunity to observe a considerable number of cases of heart affections will easily find confirmation of the fact that in individuals previously normal, and solely through the most different forms of overstraining, the heart may be brought first to acute dilatation, and finally through its repetition to permanent dilatation, with all its consequent phenomena.

ON FUNCTIONAL DISORDERS OF THE COLON.*

BY ERNEST W. HEY GROVES, M.D., M.S. LOND., F.R.C.S. Eng.,

ASSISTANT SURGEON TO THE BRISTOL GENERAL HOSPITAL.

UNDER this heading it is proposed to describe all conditions of the colon which are associated with marked constipation without the occurrence of any gross disease. It includes, on the one hand, the extreme cases of idiopathic dilatation of the colon, most of which are congenital; and, on the other, those cases of chronic constipation which are probably due to a sluggish action of the large intestine. The necessity of considering such widely differing conditions together arises because of the existence of many intermediate groups of cases in which the colon is lengthened, dilated, and kinked and severe constipation exists, but it is impossible to determine whether the dilatation or constipation is the primary event. In other words, there are many cases in adults in which it is difficult to decide whether the colic hypertrophy is congenital or acquired, whether it is idiopathic or secondary, whether it is the cause or the result of chronic constipation. It is quite possible for well-marked dilatation of the colon to exist without causing any characteristic symptoms. For example, Baron relates the case of a boy, nearly two years old, who died from scarlatinal nephritis and in whom a well-marked mega-colon was found at the necropsy which had given no symptoms during life.

The following case, which occurred recently at the General Hospital, illustrates the latency which sometimes characterises the disease. A labourer, aged 61 years, was admitted to hospital in March, 1909, suffering from cyanosis, shortness of breath, and cedema of the legs. He had had no previous illness. There was great distension of the abdomen, but no tenderness or dulness to percussion. He died suddenly within 24 hours of admission. Post mortem no disease was discovered except an enormous dilatation, with lengthening of the colon. The following were the chief measurements:—

Part.		Len	gth.	No	ormal.	Cir	cumferenc	e.	Normal.
Cæcum .	••	3 in	ches	25	inches	••••••	15 inches		11 inches
Ascending colon	ļ	134	,,	4	••		_	····•	
Transverse colon									_
Descend- ing colon									_
Sigmoid		33₺	••	24	**	•••••	15½ inches		7 inches
		Total	len	gth, 92½	inches ;	normal	, 56; inche	8.	

The ascending and sigmoid portions of the colon were most markedly kinked, the sharpest angulation occurring 11 inches from the rectum. But there was no evidence of acute obstruction nor of peritonitis.

It may be possible, therefore, that a dilated colon exists as a congenital defect, but gives rise to no symptoms until adult life. It is well known, on the other hand, that any mechanical obstruction to the bowel will cause the intestine above to be affected in exactly the same way as is found in the congenital disease. Any adult case may, therefore, be one of congenital or acquired disease, but it is seldom possible to be sure which.

Historical.—The existence of extreme dilatation of the colon without any actual stenosis or obstruction has been described by a few authors many years ago. Billard,² in the early part of the nineteenth century, described a necropsy on a child 6 days old, in whom the whole of the colon was hypertrophied and sclerosed. Ammon ³ in 1822 related the

^{*} The superior figures throughout this article refer to the bibliography printed at the end.

case of a child who died soon after birth in whom the colon and rectum were dilated. Oulment4 (1843) and Favalli5 (1846) and Banks (1846) described cases which rather resembled those of chronic constipation with secondary distension of the large bowel. Gay 7 (1854) published an account of a boy, aged 3 years, who died from typhus fever, and in whom the whole large intestine was greatly distended, as he thought by paralysis. Instances of the more typical form of congenital dilatation of the colon were described by Henoch (1861) in a boy two years old; Jakobi⁹ (1869), Barth ¹⁰ (1870), Peacock ¹¹ (1872), Gee ¹² (1884), Bristowe ¹³ and Morris ¹⁴ (1885). In 1886 after Fütterer, Middledorpf, ¹⁵ and Garrille Morris ¹⁴ (1885). Gaum 16 had described isolated cases, Hirschsprung 17 collected all these previously published facts, together with his own observations, and gave an account of the general features of the disease. Hence it is known in Germany as "Hirschsprung's Krankheit," but it is evident that the facts do not justify this personal nomenclature, and it is better, therefore, to give it the descriptive name of "idiopathic dilatation of the colon." In its well-marked congenital variety it is a very rare disease, but if all cases of dilatation of the colon with severe constipation but without any mechanical obstruction be included, then it is possible to collect from the literature about 150 cases, and upon an examination of these the following account is based.

Pathological anatomy.—The whole colon alone may be distended, or more frequently only special sections are affected, the pelvic colon having the most marked tendency in this direction. In 93 cases where this point is specially mentioned the distribution of the dilatation is as follows:—

The degree of dilatation varies within very wide limits in different cases, and in the same case at different When the abdomen is opened the distended viscus is often described as resembling the stomach, or as being as thick as a man's thigh. It is frequently 18 centimetres in diameter, and between 50 and 60 centimetres in circumference in adult cases, and in infants it may reach 35 centimetres round. In several of the recorded cases the size of the distended coils varied very much under different conditions. In one of my cases the colon, which was so large as to obscure all the rest of the intestines at the time of the first operation of colostomy, was only of normal size when it was excised. Hawkins 19 describes a case of an infant 3 weeks old who died after an exploratory laparotomy, the whole colon down to the splenic flexure being so dilated as to cause a visible tumour through the parietes, and yet after death this part had resumed its normal appearance. This point will be referred to again in discussing the question of "phantom tumours" caused by colic In most cases the length of the colon is dilatation. increased as well as its diameter, but this does not always In the two following lists, taken from Löwenstein's article, 18 these facts are illustrated:

Cases illustrating the abnormal length of the colon.

Author. Age.			L	engi	th.	Greatest circumference				
Tittel 29	14	years		107	centimetres		21.3	centimetres.		
Berghinz 41	14	,,		98	,,					
Fenwick 42							20			
Concetti 43								,,		
Barth 10										

Cases of great dilatation with no increase in length of colon.

Author.	Age.	Length.
Bernheim Karrer 44	1 year	 83 centimetres.
Gourevitch 45	14 years	 73 ,,
Graanboom 46	4 months	 67 ,,
Baron 1	2 ,,	
Bjorksten 47		
Pfisterer 48		
Ring 49	5	19

In comparing the ages in these two lists, it will be noted that cases where there is no increase in length are generally very young children, which suggests that dilatation is the primary condition, and the increase in length comes on later as a part of the general hypertrophy. The capacity of the colon is greatly increased and in many cases it seems to be

only limited by that of the abdomen. In most cases this may be indicated during life by the large quantity of fluid which can be injected per anum, but this test is open to two fallacies, one to the fact that a kinking of the gut may prevent the fluid from filling the colon, and the other to the rapid absorption of the fluid as it runs in. The following figures relate to the amount of fluid that could be poured into the colon post mortem:—

Author.	Age of patier	Capa	city.		
Concetti 43	. 2½ years		4 litres.		
Le Roy des Barres 50			5	,,	
Barth 10			6	,,	
Futterer 15			8	**	
Peacock 11	28		16	**	

The enlarged, and often lengthened, coils of colon become necessarily kinked and twisted in order to accommodate themselves to the cavity of the abdomen. This is most notably the case with the transverse and pelvic portions. The former is dragged down by the weight of its contents so as to form a long dependent loop hanging into the pelvis. The latter assumes the horse-shoe or Ω shape, which is so characteristic of volvulus, and, indeed, as is mentioned later, it not infrequently is the preliminary stage of sigmoid volvulus. The normal flexures become exaggerated, the first part of the transverse colon with the hepatic flexure presenting a complicated folding like the letter W, and the two limbs of the splenic flexure lying in contact with each other for several inches. And lastly, there is in nearly all cases involving the pelvic colon a well-marked sharp kink at the beginning of the rectum. So much is this the case that Hawkins 19 remarks that it is often possible to wash out the gut through a rigid rectal tube when a flexible one will not pass into the pelvic colon.

The outward appearance of the bowel is normal as a rule, but white or œdematous patches occur on its surface sometimes. In children the lymph glands are often increased in size and number. The wall of the colon is usually thickened (6 millimetres) and this hypertrophy, whilst affecting chiefly the circular muscle layer, also involves the mucous membrane and submucous tissues. The tænia are present as broad bands 3 or 4 centimetres wide, and in some cases the longitudinal fibres exist as a continuous coat round the bowel. This thickening of the muscular coats is rightly insisted on by many authors (cf. Hawkins) as a clear evidence of the effort made by the bowel to empty itself of its contents, and is comparable to the hypertrophy of hollow muscular viscera—e.g., the heart or bladder—which often accompanies dilatation. In some cases (Treves, 54 Dodd, 28 Hawkins, 19 Case 9) one or more segments of the bowel are remarkably contracted, and when the contracted portion lies distal to the dilated it is probable that the former condition may be the cause of the latter.

According to the majority of authors inflammatory changes are comparatively rare, at any rate in their grosser forms of external adhesions or internal ulceration. The mucous membrane is often infiltrated by leucocytes and its connective tissue much increased. Ulceration which is secondary to fæcal impaction is sometimes found, and is to be inferred in those cases where much blood-stained diarrhæa occurs during life.

According to Löwenstein, 18 the blood-vessels—especially he arteries—are thickened and their lumen partly obliterated. Unfortunately the condition of the nerves is seldom mentioned, but in Gee's case 12 they were remarkably hypertrophied, and Geddes 74 has recently described an identical condition. In extreme degrees of the disease and in chronic cases the pressure of the dilated colon produces obstruction to the venous circulation, with resulting ædema and an enlargement of the collateral circulation. From the same cause the urine may be scanty and albuminous, or there may be pain in the front of the thighs from pressure on the anterior crural nerves (Grey). 32 The diaphragm becomes pushed upward, and the thoracic viscera correspondingly compressed and displaced. The heart's apex is lifted to the third or fourth interspace and the bases of the lungs are collapsed. These extreme chest abnormalities are only found in children; probably they are incompatible with prolonged life.

Physical signs.—In well-marked cases of the disease the abdomen presents an extreme degree of distension, being globular or barrel-shaped, and in children the contrast

between the blown-out belly and the contracted chest and the sunken face is very striking. The girth of the abdomen is usually greatest above the umbilicus, being, e.g., in a case related by Fenwick, 12 26 inches (65 centimetres) above and 24 inches (60 centimetres) below.

In young children the chest is very stunted in its growth and capacity, measuring often only 10 to 12 centimetres from the top of the sternum to the ensiform cartilage, and being only one-fifth or one-sixth of the distance between the ensiform cartilage and the pubes. The margin of the ribs is everted, the subcostal angle being widely opened out. The whole abdomen is tympanitic and the liver dulness is lessened as a rule, and in many cases it is comparatively flaccid and soft. Occasionally fæcal masses can be felt and even indented by pressure (Woolmer 33), and this sign is more likely to occur in cases caused by chronic constipation in adults than in the congenital variety in children. When these hard fæcal masses do occur, they are very likely to give rise to an error in diagnosis. There is no ascitic fluid found in the abdomen, and this fact seems to weigh very strongly against the existence of inflammatory changes in the peritoneal cavity. The parietal wall is very thin and often covered by large veins. Through it can be seen the distended coils of intestine so clearly that the part affected by the dilatation can often be made out before the abdomen is opened. The most usual disposition of these loops of colon is in a vertical direction. The distended pelvic colon lies usually as a large n, the apex of which may touch the costal margin. When the ascending and transverse colon form visible loops they, too, are disposed in the long axis of the abdomen. Next to the pelvic colon the ascending colon seems most frequently to form a visible coil, and the descending colon is most rarely thus affected. From time to time the distended coils can be observed slowly to contract, and a sluggish peristaltic wave is often accompanied by audible borborygmi. On rectal examination very different conditions may be found. In a few cases the sphincter ani has been found tightly contracted (Treves, 54 Grey, 52 Wilms, 55 Hawkins 19), but that this is not an essential feature of the case is shown by the majority not presenting it, and further, by cases in which it is patulous or paralysed (Kredel 56). A painful fissure in ano is a common result of the excoriation produced by the passage of hardened fæces.

Onset.—The severity of the symptoms varies very much in different cases, and in the same case from time to time. Remaining latent generally for some time after birth, insidiously arising after the distension has become wellmarked, and varying with treatment or diet, the symptoms of colic dilatation sooner or later become so severe as to cause death, either by pressure on the chest or by intestinal obstruction or perforation. The latent period is difficult to estimate, because when the condition arises in adults it is always in doubt whether there has been a long-standing or congenital dilatation of the colon, or whether this has arisen secondarily to the constipation. But that true and extreme cases can exist without symptoms is proved, not only by Baron's case of scarlatina, in which it was found at the necropsy, having given no symptoms during life, but also by the many cases in which, after the bowel had been mechanically emptied, the patients remained well for long periods (Brooks, ⁵⁷ Fletcher and Robinson, ⁵³ Grey, ⁵² Hawkins, ¹³ Case 5). But the great majority of even adult cases give a history of obstinate constipation which dates back to their childhood. Some writers (Hale White, 59 Hawkins, 19 Fenwick 12) have laid stress on the condition never being found in the new-born, and have argued from this that there is no proof of its congenital origin. But in addition to the improbability of such a condition occurring within a few weeks or months of birth without the existence of any obstruction there are several instances recorded in which the child was born with a greatly distended abdomen which subsequently proved due to the dilated colon (Escherich, ¹⁰ Stirnimann, ⁰¹ Hobbs, and de Richmond ²¹). In Escherich's case the newly born child had a girth of 77 centimetres, with a body length of 37 centimetres.

The first onset of symptoms, apart from mere constipation, may be in earliest infancy, occurring when the child is at the breast, in childhood, or in late adult life. Hawkins draws attention to the fact that most cases present themselves for treatment before 10 years of age, and that nearly all the adult cases are over 40, the incidence between these periods adult cases are over 40, the incidence between these periods chondriac regions, in the position of the ascending colon. being very rare. As exceptions to this, however, may be

mentioned a man of 28 (Woolmer ¹³), a woman of 21 (Brooks ¹⁷), and a woman of 36 (Groves). ⁷³ In 91 cases collected by Löwenstein is the time of onset of symptoms was as follows: 55 "since birth," 13 in first year, 11 between 1 and 20, 9 later than 20, and 3 at 70 or over.

The sex incidence shows a very marked preponderance of males, and this is more marked in the infant than in the adult The actual figures given by different authors indicate varying proportions, but all agree in the above statement. In 122 cases, 94 were males and 28 females (3.35:1). In infancy the proportion of males to females is 7 or 10:1; whilst in adult life it is 2 or 3:1.

Symptoms.—Obstinate constipation, loss of appetite, and emaciation are the chief features of the disease throughout its whole course. Usually the constipation is quite unmistakeable, the interval between the stools being over a week. In my case the patient would go for three weeks without an action, Grey's two or three weeks, '2 Johannessen's five weeks, 22 Roth's six weeks,23 Rolleston and Haward's nine weeks,24 and Gay's three months. Usually the constipation is well marked before distension occurs, but in other cases the bowels act quite regularly. This is important, because if the possibility is not recognised the nature of the case may be quite overlooked. Just as it is very common to get distension of the bladder associated with incontinence, so, too, there may actually be diarrhœa in cases of fæcal stasis. It is not enough for there to be a regular evacuation of the bowels, but unless the quantity evacuated is equal to that received by the colon fæcal accumulation must take place. It is common for attacks of diarrheea to alternate with constipation, and when this occurs the patient is often much relieved, and the distension diminishes, but the abdomen seldom resumes its normal proportions. The presence of blood and much mucus in the motions is rare, and when it occurs with diarrhœa it is of grave import, indicating ulceration of the intestine.

Emaciation very soon becomes pronounced in children, and is partly caused by the loss of appetite. In adults it is of great importance, because it indicates that the metabolism is being seriously disturbed. In this respect it would afford a valuable indication as to the necessity of treatment. As long as a case of constipation, however severe, remains well nourished, it will probably yield to drugs, enemata, and diet. But when progressive emaciation sets in, the patient has not long to live, unless some radical treatment is adopted. And with the faulty nutrition there is generally some affection of the nervous system. In infants drowsiness and convulsions are common, and the latter may be the cause of death. In Langmead's case 25 the child suffered from severe tetany. With older children the mental development may be greatly impaired (Grey 52), and in adults various degrees of neurasthenia or melancholia are very common. If persistent diarrhœa takes the place of constipation the temperature rises, symptoms of peritonitis set in, with vomiting and convulsions, indicating the occurrence of a perforation. But with the exception of this possibility, vomiting is quite unusual and is never stercoraceous. In young children various lung complications, such as bronchitis or broncho-pneumonia, are common causes of death, being caused, no doubt, by the great pressure on the thoracic viscera.

One other sign, that of the phantom tumour, remains to be discussed. The term is applied to an abdominal swelling which disappears when the patient is anæsthetised. It was first described in this connexion by Fitz 26 in 1899, and by Richardson 27 in 1901. In both these cases the patients were women of the neurotic type, in whom a "phantom tumour" might be expected. At first the diagnosis was regarded as being purely that of neurosis when it was found that the swelling disappeared under an anæsthetic. But in both cases the patients developed a degree of dilated colon which required surgical treatment.

In one of my cases 73 the same phenomenon was observed some time after the patient had had an ileo-colostomy performed. She was a woman, 37 years of age, who undoubtedly wished to attract attention to herself, for she was in the habit of making her thermometer register an alarming temperature by placing it against the hot-water bottle. She complained of attacks of abdominal pain, and at these times a very large resonant mass rose up in the right loin and hypo-

several days together the abdomen would be perfectly Then for two or three days the abdomen became distended, and at intervals the localised swelling would reappear. On one occasion, when it was well marked, she was anæsthetised, and it slowly subsided as she became un-conscious. She left the hospital for several months, but she then again complained of severe pain and begged for some further operation. On this occasion when she was in the hospital there was noticed a wave of contraction slowly passing along the swelling, from below upwards and to the left. At the operation, however, the ascending and transverse colon, which was excised, presented nothing unnatural in size, length, or appearance; and in Hawkins's 19 fourth case, in a boy three weeks old, a coil of colon proximal to the splenic flexure, which was greatly distended during life and during an operation, appeared to be quite normal after death. The phenomenon probably indicates a profound disturbance of the neuro-muscular mechanism of the bowel.

The faces.—Whilst the capacity of the colon is greatly increased it is not always filled with fæces, but is often distended by gas. In the chronic forms, and especially in adults, there may be a great accumulation of hard, solid material, so that as much as a kilogramme (2 pounds) can be washed away at a time. In some cases it is so hard that it has to be broken up in the rectum before it can be removed, and in Brooks's 57 case there was a mass of vegetable fibre in and in Brooks's ⁵⁷ case there was a mass of regements, which the pelvic colon weighing 20 ounces (560 grammes), which we provide the put. Usually had to be removed through an incision in the gut. the first fæces removed are slate-grey and very offensive, but in several instances (Hawkins 19) it is noted that they were remarkably odourless. In the more acute conditions of obstruction which often precede surgical interference the contents of the bowel are quite fluid, and can be evacuated through a tube.

Course of the disease.—The condition is essentially a chronic one, and except in the case of young children the patients may live for months or years after wasting has set in. One case is related which died 6 weeks (Pfisterer 43) and another 11 weeks (Hirschsprung 17) after the onset of symptoms. At first purgatives afford relief, but soon they become inoperative; then enemata are tried and give a longer period of respite. In several instances after the bowel had been emptied by operative or mechanical means the patient has remained well for an indefinite period (Fletcher and Robinson, 55 Brooks, 57 Grey, 52 Hawkins 19). The earlier the symptoms manifest themselves, the more rapid is the course of the case likely to be, and, indeed, in most of the adults a history of chronic constipation goes back as far as their memory. The actual cause of death may be some lung disease or convulsions in infants; perforation, peritonitis, or toxemia in any case.

Etiology.

The exact causes of this group of diseases will always remain in obscurity, because so many factors are involved and it is a matter of opinion in any given case as to the relative proportion of the different factors in bringing it about. At least seven different contributory causes have been recognised and it will be convenient to consider them severally.

1. Obstruction, in the sense of an actual blocking of the lumen of the gut, probably never occurs as a primary condition. When the bowel is examined post mortem there is usually no obstacle to the free passage of fluid throughout its lumen, and this is certainly the case after the colon has been removed. Occasionally, however, a hard mass of fæces becomes impacted in some part of the lumen (Brooks 57), and when this is removed the symptoms of the disease may disappear. It is extremely probable that this obstruction by fæcal masses often occurs as a secondary cause when the condition is of long standing. Having regard to the fact that in normal conditions the fæces do not assume a solid consistency before the lower part of the transverse colon is reached, this is perhaps one reason why the lower part of the bowel is more often affected than the upper. A degree of kinking may be present which affords no obstacle to the passage of fluid contents, but when a hard solid mass has to negotiate the same passage-e.g., the splenic flexure, or the sharp angle between the pelvic colon and rectum—it may well be that a blocking occurs. This may not be an absolute obstruction, but it is well known that a partial or intermittent obstruction of a duct is the

most potent cause of hypertrophy and dilatation of the hollow viscus behind it, as is seen so well in the case of obstruction of the ureter by a loose calculus, or of the urethra by a stricture.

- 2. Increased length.—There is no reasonable ground for supposing that the mere increase in the length of a healthy piece of bowel can cause any difficulty in the passage of its contents. The small gut, which is four times as long as the large, never is subject to the disability we are considering. But the large bowel is so tied down to the parietes that its undue elongation almost necessitates its taking the form of sharp turns and twists, and if the increased length has any share in the production of obstruction it can only be in this way. That this lengthening is not, however, a necessary condition is shown by the many well-marked cases already referred to in which the colon is of normal length. But several facts, on the other hand, seem to show that it must be regarded as a contributory cause in most cases. One of these is the sex incidence. is known that the colon is longer naturally in the male than in the female. Although this greater length may not amount to very much yet it is chiefly distributed in those parts of the bowel, such as the pelvic colon, which are not laid down in exact lines against the parietes. And for the same reason, therefore, volvulus of the pelvic colon is much commoner in men than in women. There seems to be no other explanation of the greater prevalence of these two diseases in the male sex than the greater length of the bowel.
- 3. Kinking.—That the kinking of the various dilated loops upon one another must greatly embarrass the onward flow of the fæcal contents is the most natural explanation, and it is irresistibly suggested by the condition of the abdomen filled by huge coils which are doubled sharply upon themselves. It is a matter for simple experiment that if a length of bowel removed from the body be laid in a confused heap in a basin there is some difficulty in filling it with water. One coil fills, and at the point where it is doubled upon itself the next coil is held closed. But whilst this does not represent the physiological condition in which the bowel itself affords the propelling force, it shows the increased difficulty caused by a sharp turn in the gut. It is particularly in those segments of the bowel which lie proximal to the natural or exaggerated angles of the colon which become most affected by dilatation. Thus the pelvic colon has a sharp kink between itself and the rectum, the ascending and transverse colon end at the splenic flexure, and it very often happens that it is one or other of these sections of the bowel which alone is dilated. The descending and iliac colon, on the other hand, which form the straightest part of the large intestine, are the parts most rarely affected by this disease
- 4. Muscular insufficiency.—As far as can be judged from the structure of the affected colon there is certainly no muscular weakness. Whilst the whole gut wall is much thickened, being often 6 millimetres-i.e., about three times as thick as usual—this hypertrophy affects chiefly the circular muscle. And that this hypertrophied muscles does contract vigorously during life is shown by the visible peristaltic contractions seen through the thin parietes, especially in children. It is probable, however, that when any segment of the bowel is dilated beyond a certain point, the muscle is so stretched that it becomes paralysed, for this is consistent with what is known of muscle physiology throughout the body. And judging from the analogy of other obstructed muscular viscera, the dilatation and hypertrophy are probably antagonistic to one another, and when the dilatation has overstepped a certain degree the hypertrophy is unable to keep pace with it. Further, it must be considered that with the increase of muscle there goes a certain degree of fibrosis, with an increase of cellular and connective tissue, which indicates a chronic degeneration of the muscle.
- 5. Spasm.—It is quite clear, however, that the muscular act which is necessary for the propulsion of the colic contents is not a simple contraction, but an orderly succession of such contractions by the circular muscle fibres coördinated with contractions of the longitudinal tænia. And at the time when the muscle is hypertrophying, to meet some difficulty caused by kinking or by constipation, if one particular section becomes stronger than another it may very easily actually hinder rather than help the fæcal stream. In several cases it has already been mentioned that the

sphincter ani has been tightly contracted, and, after all, the internal sphincter is only a specialised part of the circular muscle. In other cases (cf. especially Hawkins, 10 Dodd, 21 Treves 54) there has been a tight spasm of a considerable segment of the colon below the dilated portion. This in the cases mentioned affected a part of the pelvic colon, and was no doubt a large factor in the cause of the general condition. It may well be that this occurs very often in a lesser degree which disappears post mortem.

6. Disorderly nerve impulses. - Inasmuch as the muscular contractions are controlled by the nervous system, what has been said in the last paragraph applies with equal force to any irregularity in the passage of nerve impulses. The only anatomical ground for regarding the nerves themselves as abnormal is found in Gee's and Geddes's cases, 12 74 where the nerve plexuses were hypertrophied. But the disorder is one of function rather than structure. If the facts of the physiology of the colon be considered it is evident that the nerve control of the colic movements is very complex. Not only is there the coördination of peristaltic with antiperistaltic movements, but the different sections of the bowel are affected differently by nerve impulses. Whilst the greater part of the colon is under the control of the inferior mesenteric plexus, the lower portion-including the descending and pelvic portions—is made to contract by stimulation of the lower sacral nerve roots. This may serve to bring about that very spasm of a distal segment and dilatation of a proximal segment which we have seen does actually exist if there is any incoördination of the nerve impulses. In adults, at any rate, there is often noticed an association between conditions of neurasthenia and colic dilatation, which may be explained on this hypothesis.

7. Constipation.—How far constipation is the cause, and how far it is the result, of dilatation of the colon is a most debateable point in the etiology of this condition. But inasmuch as constipation is merely a negative condition resulting from an altered activity of the bowel, an altered consistency of the fæces, or a voluntary resistance of the desire for defacation, it seems unreasonable to regard it as the prime cause of the condition of the bowel, since it itself must be secondary to one of the above-mentioned conditions. The fæcal material is an inert passive matter in the grasp of an active vital tube, and, therefore, any stagnation of fæces must primarily be due to changes in the gut, rather than vice versa. But if constipation has once been caused by the firmness of the fæces, by neglect of evacuation, or by mechanical or vital insufficiency of the bowels, it may be a potent factor in increasing any abnormality of the colon. By the mere bulk of the fæces dilatation may be produced; by the increased absorption of bacterial products the muscular wall may be injured; the presence of a hard fæcal mass may block a kinked gut. But in any given case it is well-nigh impossible to say how large a share constipation has had in accentuating the pre-existing condition. One criterion there is, however, which helps to distinguish between cases of primary and secondary colic dilatation, and that is the history. In cases in which the patient has had obstinate constipation since infancy there is a strong presumption that the colon is dilated. In cases where constipation appears for the first time in adult life, and is found to be associated with dilatation of the colon, the latter may be secondary, but it is even then impossible to be sure that the anatomical abnormality has not always existed but been overcome by muscular hypertrophy, and that in later years the hypertrophy fails and gives place to dilatation. Two further signs there are which seldom occur in secondary dilatation: these are great abdominal distension and visible peristalsis. If these tests-viz., history, distension, and visible peristalsis—be used to distinguish idiopathic dilatation of the colon from the mere results of chronic constipation, then it is found that in the latter group there are present in the colon a somewhat different group of changes from those above described. I have elsewhere 75 described a well-marked case of primary constipation, with its secondary consequences, and I may summarise them here as being: A dilated condition of the cæcum, ascending and transverse colon; kinking of the hepatic and splenic flexures, and the displacement, with kinking, of the transverse colon; downward dragging of the pyloric part of the stomach, and the consequent acute flexion of the duodenum.

Biliary lithiasis and appendicitis are also no doubt remotely

connected with constipation; but in my case there was no evidence of any inflammatory adhesions binding the surface of the colon to neighbouring viscera. When I saw the specimen first, I thought that these did exist with the gallbladder, but further consideration leads to the conclusion that it is merely a peritoneal ligament; and it is certainly remarkable that throughout the literature (except in Lane's papers) all mention of peritoneal adhesions is absent in the description of the actual cases. The facts illustrated by the specimen referred to differ from those in idiopathic dilatation very little. The differences are two: the dilated part of the colon is the upper portion, and there is no evidence of muscular hypertrophy, whereas in idiopathic dilatation it is the pelvic colon which is most often affected, and muscular hypertrophy is well marked. A further point of distinction lies in the sex incidence. In idiopathic dilatation of the colon males preponderate, in adults in the proportion of 3 or 2:1, whereas in chronic constipation the proportion is more than reversed. In Lane's series of 39 cases of "chronic constipation," for example, 5 were males and 34 were females (1:7).

How many of the other affections which may be found in any case of constipation can be regarded as resulting from this will be a matter of opinion or speculation. If we accept Metchnikoff's idea that the intestinal decomposition lies at the root of all senile tissue degeneration, then we shall be prepared to regard everything abnormal associated with constipation as resulting from that. For instance, in my case scoliosis, enteroptosis, suppuration, and dislocation of the hip may have occurred as the direct or remote results of absorption of bacteria and toxins from the colon; but such a view is utterly at variance with the spirit of scientific deduction, which demands evidence rather than speculation in support of theories.

Mr. Arbuthnot Lane 51 has, however, followed the speculative line in the treatment of this subject to its extreme limit. According to this author the following conditions are caused by chronic constipation: fixation of the colon, especially the ascending and pelvic portions, by peritoneal adhesions; atrophy of the wall of the sigmoid flexure; the formation of special "mesenteries" at the hepatic and splenic flexures which drag upon the colon and produce kinking; adhesions of the transverse colon to the adjacent limbs of the ascending and descending colon; adhesions at the base of the appendix, dragging upon the right kidney; distension of the small intestine; pain in the right renal region from dragging on "adhesions" at the hepatic flexure, and in the sacro-iliac region from the dragging of the cæcum; dilatation of the stomach by "gases of decomposition" and by the back pressure through the small intestine; offensive breath, with a general "grave-yard" smell; mental depression and drowsiness, loss of fat, pigmentation of the skin over the face and in the flexures; matting of the ovaries and Fallopian tubes, displacements of the uterus, and loss of uterine tone; cystic degeneration of the ovaries and breasts, and sterility. But as Lane has brought forward no detailed description of actual cases which bear out his facts and no evidence which supports his theories, they must stand as the mere expression of opinion which is not supported by that of other writers.

Regarding the peritoneal "adhesions" I have pointed out that these are often merely normal variations of peritoneal folds, and that the surface of the colon is remarkably free from adhesions to adjacent structures. The process by which the ascending colon becomes more firmly tied down to the parietes than is normal is explicable much more simply than by supposing its surface to be dragged down and fixed to adjacent structures by inflammation. When the colon dilates its peritoneal covering will be insufficient and will become stripped off from its posterior aspect, so that instead of only a fourth of its surface being without peritoneum, nearly a half may so become destitute. The same reasoning applies to changes in the length of the gut. When a fixed part of the colon increases in length it becomes thrown into folds, and the peritoneum covering it will stretch in the form of tight bands from fold to fold, instead of always dipping down into the crevices between the dilated If these bands were inflammatory they would pouches. probably be adherent to structures outside the bowelthey are not-and would be tightly fixed to the bowel instead of being easily removed from it. But if adhesions are regarded as always resulting from some definite inflammatory

disease—e.g., appendicitis, gall-stones, or gastric ulcer—they will require direct surgical treatment, where this is possible, and even if obstinate constipation be associated with such conditions, it will be far more reasonable to classify these cases as chronic obstruction due to adhesions, rather than to confuse them with simple constipation or colic dilatation. In several of Lane's own cases (Cases 17, 19, and 21) this contention is proved by the sequence of events. That is to say, the patients had pain vomiting, and constipation, the abdomen was opened, and adhesions were found connected with gastric ulcers. The cases were treated, nevertheless, as though due primarily to colic stasis by ileo-colostomy or excision of the colon. This treatment either proved fatal (Cases 17 and 19), or had to be followed by a subsequent gastro-enterostomy, after which the patient made a good recovery (Case 21).

To summarise, then, the etiological factors, it is evident that any or all of seven causes may combine to bring about the final condition in extreme dilatation of the colon. These are:—obstruction by fæcal impaction, increased length of the colon, kinking, muscular insufficiency, local muscular spasm, ncoördinated nerve impulses, and constipation. But it cannot be certainly said that any one of these has been proved to be of primary and universal occurrence, the probability being that more than one factor exists primarily in most cases and that the others may play a secondary part

The classification of these conditions will depend largely on the view taken of their etiology. It is most commonly made into (1) primary or idiopathic, and (2) secondary or acquired dilatation, and although this distinction no doubt exists, it is of not much value because it is impossible to be sure that dilatation may not have existed for a long time in a latent condition. The more useful classification would be made on an anatomical basis, because this can always be made by radiography, and it is an important basis for treatment. In this we should distinguish three main groups: (1) proximal dilatation affecting the ascending and transverse colon and the execum; (2) distal dilatation affecting the pelvic colon, and much more rarely including the descending colon and rectum; and (3) general dilatation affecting the whole colon. And in cases of obstinate constipation without much dilatation this same classification will hold good if the term stasis be substituted for that of dilatation.

Treatment.

Whilst it is evident that in its extreme form "idiopathic" dilatation of the colon is one which requires surgical treatment, and that in its slight grades medical and dietetic measures will suffice, there must always remain an intermediate group of cases in which there is a difference of opinion as to what should be done.

Diet.—Dealing first with the slighter stages of the disease, most authors advise easily digested diet which leaves comparatively little residue—such being, of course, milk, fish, eggs, and white bread. But it is possible that in some cases the colon will react better when stimulated by bulky food residue, such as that left by brown bread, porridge, and vegetables, and Concetti da advocates such a diet as being the most satisfactory. There must, however, be some difficulty in determining if the colon is really emptying itself when fed with the coarse food. The motions may be bulky and even regular, but, on the other hand, there will probably be a larger residue left in the colon. This point could be decided only by mixing bismuth with the food and noting the condition of the colon by radiography.

Drugs.—In almost all cases these are useless, and they are worse than useless when great distension exists. Saline aperients, calomel, castor oil, and even croton oil cause some griping, but no evacuation of the bowels. One of my cases could take two drops of croton oil without any apparent result. Probably stimulating drugs such as strychnine, iron, and aloes will be more beneficial; and Grey ⁵² relates in one case how, after clearing out the colon by enemata, he was able by means of aloes and iron pills to restore the tone of the bowel.

Enemata.—Here, again, the use of rectal injections can only succeed if the bowel is capable of responding to the direct stimulation of distension, heat, or chemical agents, and if the injections can be thrown into the affected parts of the colon. Further, if an irregular spasm exists, as has been described in some cases, this spasm may be intensified by injections.

Therefore it is that enemata have only a limited usefulness. Probably some form of oil injection is the most valuable, because it is much more slowly absorbed, and because it will soften the hard fæcal masses. In one of my cases 75 a pint of olive oil was injected by a long tube at night, and the next morning an enema of hot soap and water with one ounce of turpentine was administered. By this means a daily evacuation was procured when all other means had failed.

Other tonic measures.—When diet, drugs, and enemata seem likely to give relief, the use of massage and electricity will be of use in aiding the recovery. In theory it would seem that an electric stimulus was the most ideal treatment, but in practice its value seems to be little more than that here indicated—i.e., an adjuvant to other measures. This may be due to the physiological facts relating to the coördination of muscular contractions and nerve impulses. An electric stimulus may start a colic contraction, but this may increase an already existing spasm, or it may excite the anti-peristaltic wave more than the peristaltic contractions. Conditions which cause or favour enteroptosis should be avoided. These are the use of corsets and the usual attitude of defectation. For these should be substituted an elastic abdominal belt and defectation in a squatting position into a utensil on the ground. Physical exercise should be taken with the special view of strengthening the abdominal muscles.

Surgical treatment.—In cases of true idiopathic dilatation of the colon there can be no doubt that surgical treatment is demanded and should be performed with the least possible delay. If all the means indicated above have proved inefficacious, operation should be advised before the patient's general nutrition has suffered by emaciation and toxemia. In cases where the diagnosis is doubtful and obstinate constipation is the most prominent feature, the indications for operative interference would seem to be as follows: A long history of constipation dating back to childhood and indicating probably a congenital defect in the colon; failure of diet, drugs, and enemata to afford permanent relief; marked and increasing distension of the abdomen; visible peristaltic contractions; progressive loss of flesh.

In comparing the results given by medical and surgical treatment respectively, Löwenstein 18 gives the following figures relating to 103 cases:—

But it has to be borne in mind that many of these cases occurred at a period when surgical interference was only resorted to as a last resource. Lane 31 has published accounts of 39 cases of so-called chronic constipation on whom he operated with 9 deaths (23 per cent.), but of these 39 at least 17 are cases of inflammatory diseases (colitis 3, gastric ulcer or adhesions 5, intestinal adhesions, usually from appendicitis, 9), and excluding these there are 22 cases of simple colic stasis, with 5 deaths (22.7 per cent.). Ito and Goyesima 32 relate 21 cases treated by resection, with 14 good results and 6 deaths (28.5 per cent.). The actual operations which have been performed for these conditions are: Mechanically emptying the bowel, colostomy, colopexy, colo-colostomy, colo-proctostomy, ileo-colostomy, and colectomy.

Removal of the bowel contents.—In some instances it would appear that the colon is so inert that it cannot contract until it has been mechanically emptied of its contents, and it may be impossible to do this through the anus. Brooks, in the case of a woman, 21 years old, found a hard vegetable concretion in an enormous pelvic colon. The bowel was excised, the mass removed, and she made a good recovery. Fletcher and Robinson, in a boy, aged 13 years, removed the semi-solid fæces by simple mechanical manipulation through a laparotomy wound with a successful result. Hawkins in (Case 6) describes the case of a woman, aged 39 years, in whom the colon was incised and washed out, but she died soon afterwards.

Colostomy.—To simply fix the most dilated coil to the parietes and open it seems the simplest treatment, but it seldom gives satisfactory results (Hawkins's 10 case, where the boy, aged 1 year, died; Harris (quoted in my paper 7),

when a further anastomosis was required). This is probably due to the fact that the most dilated coil is also the most inert, and has no power to empty itself. If an artificial anus is to be made it ought to be above the seat of dilatation, and as this will have to be, therefore, in the ileum or ascending colon, such an operation will be unsatisfactory, as it will give exit to a constant irritating stream of fluid fæces.

Colupexy. - When the dilatation affects the pelvic colon only, the chief element of obstruction may be due to the kinking of the bowel, either at the junction of the pelvic colon and rectum or by volvulus formation. In either case if the loop is anchored to the parietes this will be prevented, and in several instances this treatment has had good results (Woolmer, 3 Hawkins, 10 Roth, 23 Garré (quoted by Löwenstein ''), Kummel), and in one of Hawkins's cases it succeeded even when anastomosis and resection had failed. This remarkable fact was due to the persistent re-formation of a redundant loop of pelvic colon which occurred first after the anastomosis of the limbs of the loop, and again after the first loop had been resected. An exactly similar sequence of events occurred in Richardson's 27 case.

Colo-colostomy. - This operation has also been chiefly employed in cases of dilated pelvic colon, the two limbs of the loop being joined together at their base. But inasmuch as this procedure requires that the remainder of the colon above and below the anastomosis should be normal it often fails, either from the formation of another loop or by some further kinking or fæcal obstruction. Makins 19 in one of Hawkins's cases did a lateral anastomosis of the limbs of a pelvic loop with success in a boy aged 7 years. But, as mentioned in the last paragraph, in other cases this operation has had to be followed by subsequent resection or colopexy.

Colo-proctostomy. - In Treves's case, 34 where the descending colon was dilated and the pelvic colon contracted, he excised the gut from the splenic flexure to the rectum and anasto-mosed the transverse colon to the rectum with excellent results.

Ileo-colostomy. -This is the most direct method of treating all conditions of dilated colon. By it the fæcal stream is diverted from the small intestine directly into the pelvic colon or into the upper part of the rectum. It is, however, not enough to make an anastomosis; the ileum must be cut off from the cæcum, otherwise the fæces will continue to pass on by the old channel into the dilated colon. The simplest procedure is to make a lateral anastomosis between the ileum and the pelvic colon, choosing the part of the gut as low down as possible which will come together easily. The advantage of the side-to-side junction is that it can be made as large as is necessary (about 5 centimetres long), and will not have much tendency to contract. When the anastomosis is complete, if there is occasion for haste a simple ligature round the ileum below the stoma will be enough to occlude it, and actual division is unnecessary. But usually the bowel is divided between clamps, preferably by the thermo-cautery, and the two ends are sewn up by continuous sutures. When the ileum is thus anastomosed to the pelvic colon a mesenteric band is formed, stretching across the brim of the pelvis, and the space behind this should be obliterated by one or two stitches, attaching the mesentery to the parietal peritoneum, otherwise a loop of small intestine may easily become strangulated behind the band. I have never seen any reference to this point, but I noticed the formation of this clangerous band in one of my cases, and ever since I have employed the method of stitching it back against the parietes with very satisfactory results. In two of Lane's 11 cases, one a man aged 55 years and the other a woman aged 21 years, death from intestinal obstruction followed an anastomosis operation, occurring six months after, and immediately after, the operation in the respective cases. In neither case was a post-mortem examination performed, but it is possible that the mesenteric band was the cause in both these cases.

The treatment of the distal stump of ileum affords also a matter for discussion. Except in cases of resection of the colon it has always been dropped back into the abdomen after suturing. But if the colon proximal to the anastomosis is dilated either by gas or fæces it would seem desirable to provide some means of evacuating this. The readiest method of doing this is to tie up the distal piece of ileum with a purse-string suture and thrust the gut through a stab wound in the right iliac fossa. After the median incision through this the gas and the fæces in the large bowel are allowed to escape as much as they will, and then the whole colon is gently irrigated with hot water, some of which washes on into the rectum and some runs back through the tube. In this way the entire fæcal accumulation in the colon can be removed and the chief source of toxemia eliminated. If after this the colon remains empty the ileal fistula can be closed, but if frees continue to be passed by this route—as was the case so remarkably in Harris's casethe large colon will have to be removed down to the splenic flexure or to the anastomosis.

Ileo-colostomy is a much better method of treatment than any form of colo-colostomy for two reasons. In the first place, it excludes the greater part of the dilated colon, and, in the second place, it provides a fluid stream of fæces which will pass more readily on to the rectum and anus than the solid fæces which pass down the colon. remarks that in cases of chronic constipation which he has examined by the X rays the stasis occurs in the pelvic colon, and he deduces from this fact that it would be useless in such cases to exclude or excise the proximal parts of the colon. But this ignores the change in consistency which takes place in the fæces as they pass down the large intestine. A pelvic colon may be incapable of passing on solid fæcal masses into the rectum, but may be quite capable of dealing with the fluid contents of the ileum.

Examples of cases treated by ileo-colostomy are given by Lane, 51 who treated 10 cases by this method alone with 3 deaths; in 9 cases a subsequent colectomy had to be performed, 2 of whom died; in 20 cases the anastomosis was followed by a colectomy performed at the same time, and of these 4 died. In my case 75 ileo-colostomy gave a good result for a time, but a further colectomy was necessary later, and the same occurred in Harris's patient. further points have to be discussed in connexion with the subject of the exclusion of the greater part of the colon: these are the effects produced upon the nutrition of the patient, and the necessity of removing the colon as well as partially excluding it.

The first of these questions has been the special object of the research detailed in my former paper. 55 We have proved by the estimation of the quantity and composition of the fæces passed by these two patients that there is no metabolic loss involved by the operation. In both cases the amount of proteid, fat, carbohydrate, and water passed is not greater than falls within the normal average. A still more striking proof of the actual improvement in nutrition is afforded by the patients' weight. The boy increased three stones after the colon had been excluded, and the woman increased one stone after excision of the greater part of the colon.

Colectomy. - Excision of a part or the whole of the dilated colon remains to be considered. It is undoubtedly the most radical method of treatment and the only one which gives uniformly satisfactory results—that is, if the patient recovers Richardson, 27 Clutton 30) only a portion of the lower colon has been removed, but in more than one of these (Hawkins, Richardson) a further operation of resection or colopexy has been necessitated by the formation of a fresh volvulus. Removal of the whole colon down to or including the pelvic colon has been reported in 53 cases. Lane 31 gives 20 cases where primary colectomy was performed with 4 deaths, and 9 cases after a former ileo-colostomy with 2 deaths. Ito and Goyesima 32 relate 21 cases with 6 deaths, Bossowski 1 successful case, Harris's case died, and my own case recovered. In all, there have been 13 deaths, making an operative mortality of 24.5 per cent. In all the cases that survived the patients were cured of their symptoms except in the following: Ito and Goyesima had one case which remained unchanged; Lane had one which only showed "moderate improvement," one which gave only a "fair result," and two which required further operation for gastric complications.

The fact that so many cases have required colectomy after a successful ileo-colostomy proves that the colon, although cut out partially from the intestinal circuit, still causes severe symptoms. In my own case these were pain and the occurrence of a tumour due to the distended part of the proximal colon. Harris's case 75 is particularly instructive in this respect. He first performed a right-sided colostomy in a woman who had life-long constipation. Subsequently has been closed, a Paul's tube is tied into the ileum, and the ileum was divided and anastomosed to the pelvic colon,

but after a temporary relief with natural motions the fæces again came out from the opening in the ascending colon and none passed by the rectum. This induced him to do a resection of the colon which, however, proved fatal. Now in this case there must have been an anti-peristaltic movement in the colon, which is an exaggeration of the normal anti-peristalsis; and it is probable that this occurs in the other cases in which the colon has been partially excluded. In these cases the proximal part of the colon forms a blind pouch, and the anti-peristalsis will serve to drive feecal material, mucus, and gas into this, causing painful distension and decomposition. In my case the woman had diarrhea, with the passage of blood and mucus, In my case the after the ileo colostomy, but this ceased after the colon had been removed

The age and general condition of the patient when operation is undertaken will, of course, greatly affect the prognosis. The youngest recorded successful result is that of Bossowski, whose patient was only 2 years old. In clear cases of idiopathic dilatation all successful cases of operation have been younger than 30 years (Löwenstein); and although Lane has had 19 cases over 30 years on whom he has operated, these include no less than six of his fatal cases. (Two of his remaining fatalities were, in my opinion, due to primary gastric disease, and thus all except one of the fatal operations for colic stasis were in patients over 30.)

In the lesser grades of disease, where obstinate constipation without marked distension exists, it seems unreasonable to submit patients to so severe an ordeal as that of excision of the colon. One of two other measures ought to be tried first, and probably in the majority of cases will serve for a cure, and in the remainder excision can be reserved as a last resort. The first of these is a lateral anastomosis between the ileum and pelvic colon without division of the former. Mansell Moullin 76 has related several cases where this succeeded and he has had no fatalities. The second is a still simpler operation—viz., appendicostomy-which, as far as I know, has had no mortality, although it has now been often performed for various reasons. Keetley 77 has reported several cases, and the following instance in my own practice will serve as an example.

The patient, an unmarried woman, aged 27 years, was admitted to the Cossham Hospital on Jan. 21st, 1909, sufferirg from sickness and abdominal pain. She had a longstanding history of dyspepsia and constipation, the bowels never acting without the use of aperients. She frequently vomited, but with no special relation to food. The pain was diffused all over the abdomen, and for the past six months had been so severe as to prevent her from working. Her physical condition showed little abnormal. She was rather thin; the abdomen was not distended, and she had a tender retroverted uterus. On Feb. 15th I fixed the latter by an Alexander-Adams operation, but this had but little effect on her pain. The constipation and sickness continued. was very difficult to decide whether these symptoms were due to an atonic colon or to a gastric ulcer; the want of relation between the vomiting and the taking of food made me decide against the latter diagnosis. On March 19th I performed an appendicostomy, and whilst she remained in the hospital for three weeks the colon was washed out daily and she gradually improved. return home she quickly relapsed when the lavage had been stopped. She came into the hospital again and was taught to wash out the bowel herself. She has continued to do this regularly since and is now at work. I saw her in September, and her general condition was excellent. The pain and sickness have quite ceased and she has gained weight considerably. She is anxious to dispense with the appendicostomy, but I have advised against this.

Of course, this subject of the surgical treatment of chronic constipation is one which will always evoke a great difference of opinion from both surgeons and physicians, but it may reasonably be urged that, when medical means, and especially enemata, have failed to give relief, then some surgical means ought to be employed. In the cases with no marked or progressive distension appendicostomy or a simple lateral anastomosis between the ileum and pelvic colon will probably serve as a cure. Primary colectomy or colectomy following ileo-sigmoidostomy ought to be reserved for the more typical cases of idiopathic dilatation of the colon, and then only employed after the simpler surgical means have failed to effect a cure.

employed after the simpler surgical means have failed to effect a cure.

ROYAL Institution. — The following amongst the lecture arrangements at the Royal Institution before Easter: Mr. W. Duddell, a Christmas course of six illustrated lectures on Modern Electricity, adapted to a juvenile auditory, to be given on the Tuesdays, Thursdays, and Saturdays in the fortnight after Christmas Day; Professor W. A. Herdman, three lectures on the Cultivation of the Sea; Professor F. W. Mott, Fullerian professor of physiology, R.I., six lectures on the Emotions and their Expression; Professor Silvanus P. Thompson, three lectures on Illumination, Natural and Artificial; Professor Sir J. J. Thomson, six lectures on Electric Waves and the Electromagnetic Theory of Light. The Friday evening meetings will commence on Jan. 21st, when Professor Sir James Dewar will deliver a discourse on Light Reactions at Low Temperatures.

THE RÔLE OF FATS IN THE TREATMENT OF DISORDERS OF THE STOMACH.¹

By F. CRAVEN MOORE, M.D., M.Sc. Vict., M.R.C.P. Lond.,

HONORARY PHYSICIAN TO THE ANCOATS HOSPITAL, MANCHESTER; LECTURER ON MEDICINE IN THE UNIVERSITY OF MANCHESTER; AND

R. L. FERGUSON, M.D. VICT.,

LATE HOUSE PHYSICIAN TO THE ANCOATS HOSPITAL, MANCHESTER.

THE use of fat in the treatment of gastric disorders, not merely as a foodstuff, but with the idea of producing a definite therapeutic effect on the disordered secretory activity of the stomach, is of comparatively recent development, and is based on the recognition of the frequency with which excessive secretory activity of the gastric glands obtains as a pathological condition, and on the demonstration of the depressant action of fats on the activity of

normal gastric secretion.

It had long been suspected that the presence of fats in the stomach interfered, in some way or other, with gastric digestion, a belief which was in some measure confirmed by the observation of Penzoldt, who found that a mixture of coffee and cream yielded a lower acidity of the stomach contents than coffee alone, and more conclusively by the later exact observations of Ewald and Boas who showed that the addition of bacon fat to the test breakfast associated with their names resulted in a prolongation of the period of gastric digestion and a marked diminution in the amount of free hydrochloric acid in the stomach contents. As at that period it was the prevalent belief that any deviation from the normal in the functional activity of the stomach must be in the direction of deficiency, and that the subjective manifestations of such deviation depended upon organic acid and gaseous fermentations initiated as the immediate consequence of deficiency in the antiseptic hydrochloric acid and stagnation of the contents from deficient motor power, the results of Ewald and Boas served but to emphasise the belief that the administration of fats in gastric disorders, and particularly in such as accorded with the type of acid dyspepsia, was contra-indicated in that they would induce further depression of functional activity and provide a possible source for the noxious acids themselves.

The investigations of the German school, and particularly those of Riegel and his followers, into the secretory activity of the stomach in gastric disorders demonstrated not only that excessive secretory activity of the gastric glands could obtain as a pathological condition, but that such was even more frequent than defective activity, and that in the so-called acid dyspepsia the frequently excessive acidity of the stomach contents was due not to organic acids but to an abnormally high content in hydrochloric acid itself. This conception of the disorders of secretory activity has been generally confirmed in its main theses, and in this country, although belief in the acid dyspepsia of organic acid fermentation still lingers, the frequency of pathological hypersecretion is now well recognised. To the brilliant investigations of Pawlow and his co-workers we are indebted for the basis of a more accurate appreciation of the nature and origin of these disorders of functional activity and also for suggestions as to their rational treatment. The observations of Chigin, Lobasoff, Wirschubsky, Lintwareff, and Sokoloff in the laboratories of Pawlow established that the liquid fats, olive oil and cream, were devoid of any excitative influence on gastric secretion when introduced directly into the stomach of the dog, and that their presence exerted an inhibitory influence on the normal energy of the secretory process excited by other foodstuffs.

Following on this demonstration of the depressant action of fats on the secretory activity of the stomach in the dog. certain continental observers, notably Strauss, von Aldor, Backmann, Akimow-Peretz, Piontkowski, Cohnheim, Walko, and others, began the administration of liquid fats in such morbid conditions of the human stomach as were associated with hyperacidity of the stomach contents. At first cream and butter were employed by Backmann, then emulsions of

almond oil by Akimow-Peretz and Strauss and von Aldor, and, lastly, pure olive oil by Cohnheim. Walke, and others. The results recorded were, with but few exceptions (Ewald, Fischl, Blum), so beneficial in alleviating the subjective discomfort and in improving the nutrition of the patient that the method well-nigh attained the dignity of an "oil-cure." Our own observations have confirmed in great measure the beneficial results of the administration of liquid fats in conditions of hyperacidity claimed by these previous investigators. They have demonstrated perhaps more completely than had been previously done the marked effect of such fats in diminishing the acidity of the stomach contents, and they have opened up some problems for further investigations.

It has been my (F. C. M.) practice at the Ancoats Hospital to include in the routine examination of such cases as manifested symptoms of gastric disorder (unless contra-indicated) a simple estimation of the secretory activity of the stomach. The method employed consists in the administration first thing in the morning on the empty fasting stomach of a modified Ewald-Boas test breakfast, modified to obtain what I regard as being of prime importance for comparative results, constancy of physical character and composition, consisting of 10 ounces of weak tea without milk or sugar, and four breakfast biscuits (Huntley and Palmer), which average about 30 grammes. The stomach contents are removed after an interval of one hour, the volume and appearance noted, and in the filtrate the amount of free hydrochloric acid and the total acidity are estimated approximately by titration with decinormal sodium hydrate—solutions of dimethylamidoazobenzol and phenol-phthalein respectively being employed as indicators. The results are stated in terms of the number of cubic centimetres of decinormal soda solution required to neutralise the respective acidities in 100 cubic centimetres of the filtrate. The peptic power of the filtrate is estimated by the length of a column of coagulated eggalbumin digested in 24 hours at 37 5°C. according to the method of Mett. and in some cases an approximation to the relative content in pepsin itself is made by the dilution method of Schiff and Nierstein.

This systematic investigation of the secretory activity of the stomach in all cases with manifestations of gastric disorder has demonstrated the frequency with which excessive secretion obtains, a feature which becomes obvious in the series of control analyses in the accompanying tables on comparing the values for free HCl and total acidity with the normal values, 20-40 and 40-60 respectively, for such a meal

With the appearance of Cohnheim's paper on the employment of large doses of olive oil this method of treatment was tried in a few cases, and with such obviously beneficial results, not only in diminishing the acidity of the stomach contents, but also on the subjective discomfort and on the general nutrition of the patient, that further investigation of the influence of fats appeared desirable. In some 62 cases in which there were subjective manifestations of gastric disorder, either with or without indications of organic disease of the stomach, the effect of the administration of oil of sweet almonds on the secretory activity of the stomach was determined. On consecutive days a plain test breakfast and a test breakfast preceded 30 minutes by one ounce of almond oil was given, and in the stomach contents the free HCl and the total acidity were estimated; in certain of the cases the digestive power of the stomach contents (peptic and tryptic) was also determined by the method of Mett. The stomach contents after the oil breakfast separated on standing into three layers—oil on the surface, the fluid contents with its granular sediment below, and between the two a narrow layer of emulsified oil, and but for the presence of the oil the contents were similar in appearance to those after the control meal; in no instance was there any evidence of the presence of bile pigments or of variations in the mucous content, and the quantity varied quite irregularly, being in some greater in others less than in the control.

The results of the analyses (see table) expressed in averages where a series of observations were made on any one case, show without exception that the administration of oil is associated with a marked reduction in the acid values, free HCl and total acidity, of the stomach contents. Although it is well recognised that in any individual, normal or otherwise, the acid values of the stomach contents, removed at a

definite time after a meal of constant composition, vary within somewhat wide limits, yet the constancy with which they are diminished after the exhibition of oil in so large a number of cases precludes the possibility of coincidence.

The effect, though constant, presents some interesting variations in degree not only in the several types of gastric disorder but also in the same type and the same individual on different occasions. On averaging the results in each of the several series it appears that the greatest absolute diminution in the acid values after the administration of oil obtains in those which present the highest average acidities with the plain test breakfast, and, as appears from a comparison of the average results, in the cases of gastric ulcer, duodenal ulcer, and nervous dyspepsia, irrespective of the presence or absence of any lesion of the stomach. In the individual cases also this is true of the majority; thus in 12 cases with a free HCl value of 50 or more the average absolute diminution of this value is 20, and in all but 4 the individual diminution ranges from 24 to 35.

In the cases on which a series of observations were made it was noted that whilst the diminution in the acidity was invariable it differed in degree on different occasions, and further, what is of particular interest, the effect of the oil was apparently limited to the period immediately following its administration; in no instance was there any evidence of its having a more enduring effect on the acid values of the stomach contents. The averages, and also the majority of the individual observations, further show that the absolute diminution of the total acidity exceeds that of the free HCl. This result is difficult of interpretation, since it apparently depends on a diminution of other factors than the HCl, free or combined (assuming the latter to remain approximately constant with the constant proteid content of the test meal), which contribute to the total acidity of the stomach contents, and which it might be anticipated would be increased by the liberation of fatty acids in the splitting of the neutral fat by the hydrochloric acid and the possible gastric lipase.

Turning to the peptic activity of the stomach contents it was found in 12 cases in which observations were made that the digestive power was diminished with the acid values, a result in part, no doubt, of the deficiency in HCl, but also, as shown by the dilution method, of an absolute diminution

in the peptic content of the filtrate, and which is obvious in all but No. 25 of the following six observations.

In three cases the oil was given simultaneously with the testmeal and resulted in a similar diminution of the acid values of the stomach contents.

The explanation of the phenomena following the administration of fats on a subsequent meal is a problem for the exact methods of experimental physiology rather than for the methods of clinical research. The investigations which have dealt with the matter by the exact methods of Pawlow leave it still in doubt whether the observed phenomena are due to a true depression of gastric secretion or to dilution and neutralisation by regurgitant alkaline duodenal contents.

Pawlow from his earlier experiments, in which the introduction of clive oil directly into the stomach of the dog by means of a sound resulted in a marked depression of secretory activity as tested by a subsequent meal of flesh, concluded that fat inhibits the normal energy of the secretory process, that the inhibition is central by reflex stimulation of the inhibitory nerves of the glands or the inhibitory centres of these nerves, and is not a mere mechanical effect of the covering over the mucous membrane and preventing excitation of the nerve endings. With the object of testing whether oil might act in some such mechanical way we made a number of observations in which oil was replaced by petroleum, but in no instance was there any diminution of the acid values of the stomach contents.

The later experiments of Sokoloff on animals with gastric and duodenal fistulæ showed that the presence of undigested fat in the duodenum suffices to inhibit the secretion of gastric juice and he concluded that the inhibitory effect of fat originates chiefly from the surface of the duodenal mucous membrane and not from the stomach. Boldyreff, on the other hand, following up some observations of Damaskin, found that the introduction of oil into the stomach of the dog led to an undoubted flow of bile, pancreatic juice, and intestinal juice into the stomach. Experimenting on himself and one of his associates, he found that the stomach contents removed one or one and a half hours after the ingestion of 80 cubic centimetres of a 2 per cent. solution of oleic acid in olive oil contained trypsin and a lipase of pancreatic origin. These investigations have been repeated on the human subject by already a considerable number of observers, Volhard, Faubel, Mohr, Schittenhelm, Levinsky, Molnar, Mahlenbrey, and others, but with another object-namely, of obtaining via the stomach a sample of the duodenal contents in order to estimate the functional capacity of the pancreas, and in the majority of instances it has been found that the administration of oil on the empty stomach sufficed to cause a regurgitation of the duodenal contents into the stomach.

In nine observations in which we administered 100 cubic centimetres of oil on the empty stomach, in four only where the oil was withdrawn after the lapse of half an hour was bile pigment present in the mixture, which was acid in reaction, devoid of HCl in a free state, contained pepsin, and in one case gave a very slight tryptic digestion. In the contained personach identical.

for an hour, and in four of these neither bile pigment nor trypsin was present in the mixture, which contained a small amount of free HCl and pepsin, and in one there was a faint greenish tinge of bile pigment. But, as already mentioned, in no instance was the presence of bile pigments or trypsin noted in the stomach contents after an oil breakfast.

Whatever the explanation may be, it remains that the neutral liquid fats administered before food lead to a diminution of the subsequent acidity of the stomach contents, the more so the greater the tendency of the secretory activity of the stomach to exceed the normal. Clinically, our experience of the administration of fats, such as cream, butter, almond oil, in conditions in which hyperacidity of the stomach contents has been found to exist, has shown this action of fats to be associated with a very definite amelioration of the subjective manifestations of the condition. In simple forms of hyperacidity depending on slight degrees of digestive hypersecretion (the so-called hyperchlorhydria of Riegel) the addition of cream and butter in abundance to the diet, with a diminution of the starches, will often suffice to remove the subjective manifestations. It is only in the more severe types, and particularly the severe degrees of digestive or continuous hypersecretion so commonly associated with chronic ulcer about the pylorus or duodenum, in which heartburn, acid pyrosis, the sudden gnawing pain in the epigastrium ascribed to pyloric spasm, and the vomiting of acid fluid, that the administration of almond oil is undertaken, and then in doses of 1 ounce first thing in the morning and repeated before subsequent meals if necessary. This method has proved of value in not only alleviating the symptoms which follow the digestion of food in the stomach, but also in contributing very considerably to the nutrition of the patient, and is certainly preferable to the sole use of alkalies for the purpose of neutralising the hyperacid stomach contents and so obtaining relief from the symptoms. In no case have we found that oil so administered has been badly tolerated or in any way proved objectionable.

A FURTHER NOTE UPON THE RELATION-SHIP BETWEEN AVIAN AND HUMAN TUBERCULOSIS.

BY S. G. SHATTOCK, F.R.C.S. ENG.,

LEONARD S. DUDGEON, F.R.O.P. LOND.

(From the Pathological Laboratories of St. Thomas's Hospital.)

In the Proceedings of the Royal Society of Medicine, Pathological Section, December, 1907, we published, in conjunction with Dr. C. G. Seligmann and Dr. P. N. Panton, the results of an investigation upon the above subject. Our conclusions as therein stated were as follows.

The human tubercle bacillus is pathogenic to the pigeon in a very limited degree only. It sets up no disease of the intestine or of the abdominal viscera when introduced (in sputum) with food into the alimentary tract, even for prolonged periods (six months) and in excessive quantities. It sets up a local or a local and glandular disease only, in the pigeon, when injected (in sputum) into the muscles or subcutaneous tissues. It sets up a local or a local and glandular disease only in the pigeon when injected into the muscles or subcutaneous tissues from the organs of guinea-pigs which have been infected by incculation with human sputum. The avian tubercle bacillus as tested from various kinds of birds is pathogenic to the guinea-pig in a very limited degree. The human bacillus has not, so far, in our hands, proved convertible into the avian by identical

In the present note we append the results of a series of passage experiments carried out with the object of ascertaining whether a repeated transmission of the avian bacillus through the guinea-pig would bring about any exaltation of its virulence, or whether a repeated transmission of the human bacillus through the pigeon would produce a similar pathogenic change.

In neither set of experiments has any increase whatever of virulence been induced. The avian bacillus when passed through a series of guinea-pigs produces only a local lesion and does not acquire any of the more virulent qualities which distinguish the human bacillus when injected into this animal. The human bacillus when passed through a series of pigeons continues to set up no more than a purely local lesion.

At the Ninth International Veterinary Congress held at The Hague (Sept. 14th-19th, 1909) one of the subjects diswas the transmission of avian tuberculosis to mammals. Dr. Mohler 1 insists, as we have already done,2 upon the urgency of studying the relationship between the avian and other varieties of tuberculosis, by reason of the prevalence of the avian disease and the general consumption of birds as articles of food. It is to fowl tuberculosis that Dr. Mohler has especially directed his attention. positive results arrived at by the feeding of fowls with the tuberculous organs of fowls are given, and the discovery of large numbers of tubercle bacilli in the faces suggests, it is pointed out, the ease with which the disease may be spread through the flock. In our paper we recorded both the impossibility of inducing visceral tuberculosis in pigeons by means of injections of the human tubercle bacillus in sputum and the impossibility of setting up any intestinal or other disease by prolonged feeding with tuberculous sputum; we recorded, however, the converse results of feeding pigeons with the tuberculous viscera of other birds (pheasants, &c.) dying from tuberculosis.

The fundamental question as to the relationship between human and avian tuberculosis is not touched by Dr. Mohler's observations. We cannot regard all the forms of mammalian tuberculosis (including, i.e., the human) as being identical, without proof. Dr. Mohler was able to infect the pig with tuberculosis from the carcasses of tuberculous chickens. But what disease the tuperculosis so induced in the pig would set up in man is not determinable by such an experiment.

That the avian bacillus is not physiologically identical with the human Dr. Mohler's observations prove, and so confirm those recorded by other observers, including ourselves. With the eggs laid by tuberculous fowls he inoculated guinea-pigs, using the white upon some and the yelk upon others. In none of the animals did more than a local lesion result. The spleen in one was enlarged, but though bacilli were demonstrated by smears, no lesions were visible. Neither in a second guinea-pig were tuberculous foci found, but the spleen and mesenteric glands were proved to contain bacilli by sub-inoculations of other guinea-pigs, which presented well-marked lesions (not stated to be visceral). From these, typical avian cultures were raised upon egg media. The guinea-pigs inoculated from the yelk developed no disease whatever.

These observations confirm those already made by ourselves upon guinea-pigs, using the viscera of tuberculous birds. What Dr. Mohler has failed to show is that the avian tubercle bacillus sets up in the guinea-pig the lesions that are produced by the human organism, and, this being so, the onus of proving the identity of the two rests upon those who

The Passage of the Avian Tubercle Bacillus from Guinea-pig to Guinea-pig in order to Ascertain whether it will Acquire a Higher Virulence towards the Guinea-pig.

Summary. - This series of passage experiments of the avian bacillus (derived from the pheasant) to the guinea-pig was commenced on Nov. 25th, 1907, and terminated on July 24th, 1908 The avian bacillus (in a salt suspension from the tuberculous spleen and liver of a pheasant dying from the disease) was injected into a guinea-pig on Nov. 25th. From this guinea-pig the bacillus was carried (by making a

suspension of the resulting local lesion in sterilised salt solution) into a succession of others, the transferences being made on Dec. 14th, 1907, and Jan. 13th, Feb. 18th, April 15th, May 15th, June 26th, and July 24th, 1908. In no animal did any more than a local lesion arise, accompanied in some cases with an insignificant involvement of the adjacent lymphatic glands. In the two guinea-pigs last inoculated no disease whatever ensued. As tubercle bacilli were present in the pus used for this concluding inoculation the numbers introduced must have been too few to set up even a local lesion. It will be seen, therefore, that no increase of virulence was brought about in the avian tubercle bacillus (derived directly from the diseased organs from a fatal case of avian tuberculosis) as tested by repeated passage through the guinea pig. The bacillus continued to produce only a local lesion, and acquired none of the pathogenic characters of the human bacillus from its prolonged growth in the mammalian tissues and fluids of the guineapig. It did not in the least degree acquire any virulence indicative of a transformation into the human microorganism.

The Passage of the Human Tuberole Bacillus from Pigeon to Prgeon in order to Ascertain whether it will Acquire a Higher Virulence towards the Bird.

In order to free the sputum of other micro-organisms a guinea-pig was inoculated with human sputum (which was full of bacilli) on Nov. 27th, 1907. The animal was killed on Dec. 14th, 1907, and presented the typical lesions of tuberculosis at the site of inoculation, in the inguinal and lumbar lymphatic glands, and the spleen. Two pigeons were inoculated on Dec. 14th, 1907, with a salt suspension of the inguinal and lumbar glands and the spleen, rubbed in a sterilised mortar, the injections being made into the pectoral muscle at the base of the wing. The birds were killed (35 days after inoculation). The first showed no local lesion; the spleen was normal on the surface and in section. In the case of the second bird there was a minute vellow focus at the surface of the pectoral muscle, too small to make further use of. The spleen was normal. On Sept. 23rd, 1907, two pigeons were injected with 2 cubic centimetres of a salt emulsion of human tuberculous sputum which contained large numbers of bacilli into the pectoral muscle at the base of the wing of each bird. On Oct. 10th the birds were killed. In each there was a firm, dry, brownish encapsulated focus of necrotic muscular substance. The lesions, which were of elongated form, were cut out, minced in a sterilised mortar, and rubbed up in sterilised salt solution. This was injected into two birds. On Oct. 24th these birds were killed and in each there was a narrow insignificant brownish necrotic focus in the pectoral muscle less than 1 centimetre in length. A portion of one was used to smear two slides; these showed the presence of tubercle bacilli, necrotic muscle fibre, and a notable number of cells. The rest of the lesions were made into a suspension as before and the whole injected into the base of the wing of another pigeon. On Nov. 7th this bird was killed, and at the site of the injection a necrotic lesion was found too insignificant for further use.

It was clear that the human tubercle bacillus produces in the pigeon only a local lesion and evinces no tendency to increase in virulence on four successive passages through the

The Inoculation of Fowls with Human Inberculous Sputum.

In the pigeon the intramuscular injection of human tuberculous sputum is followed only by a local lesion which eventually becomes obsolete, and never by visceral disease; nor can the pigeon be infected by means of human sputum administered by the mouth for long intervals. That what is true for the pigeon might not be true for the fowl is an obvious criticism that can only be met by experimenting with the latter bird. Yet even Nocard, who was an advocate for the identity of human and avian tuberculosis, confesses that he was unable to infect fowls by the administration of human sputum.

In the following experiments sputum was injected intramuscularly into two fowls, as it was in the case of the pigeons. The sputum used was in all cases found to contain large numbers of tubercle bacilli. An emulsion of human tuberculous sputum was made in sterilised salt solution, and with this two Buff Orpingtons were injected on Nov. 25th, 1908, into the pectoral muscle. On Dec. 18th, 1908, neither

¹ Report in The Lancer, Oct. 2nd, 1909, p. 1031.
2 Loc. cit.
3 Proceedings of the Royal Seciety of Medicine, Pathological Section, December, 1907.

bird presented any local lesion, and into one 6 cubic centimetres of sputum emulsion were injected into the pectoral muscle as before, and on March 24th, 1909, a third injection was made into the same bird, 6 cubic centimetres being injected into the opposite pectoral muscle. On April 26th, 1909, the bird which had received three injections was killed. The abdomen was opened and the spleen removed with complete aseptic precautions. It was found to be free from disease on naked-eye examination. It was rubbed in a mortar with a small amount of boiled sait solution and injected into the subcutaneous tissue of a guinea-pig's leg. The examination of the body of the fowl was then completed. None of the viscera, abdominal or thoracic, presented any trace of disease. In each pectoral muscle at the site of injection there was an extensive area in which the muscular substance was pale and indurated. The altered tissue was recognisable, on reflecting the skin, by its different colour. There was no swelling or unnatural vascularity about it, and the tissue was so firm and solid that it could hardly be parted into bundles by teasing. The change did not extend to the deepest side of the muscle. In the midst of this firm tissue were scattered a few lines of soft yellowish material, smears made from which (in both muscles) showed large numbers of tubercle bacilli and giant cells.

The microscopic sections, made so as to include the periphery of the condensed tissue and the normal muscle beyond, show that the pale indurated tissue is not necrotic, but the seat of a diffuse interstitial inflammation. The muscle fibres, which have not lost their striation, are separated by extensive groups of endothelial cells and lymphocytes. The cells have almost everywhere a definite arrangement in circular or oval groups, and many of the groups contain one or many giant cells. The nuclei of the latter are devoid of a peripheral disposition. The whole picture reproduces that met with in the case of the pigeon when experimentally injected with avian tuberculosis, but with the marked difference that whilst the avian bacilli were demonstrable with the greatest ease in the second case none of the human could be shown in the first.

There is no necrosis of the new formation. The lesion ends somewhat abruptly, and is succeeded by normal muscle, but there is no limiting zone of intervening fibrous tissue. A certain amount of fibrosis accompanies the tuberculous lesion, the tubercles or giant-celled systems in places lying in the midst of fibrous tissue.

The subsequent history of the guinea-pig inoculated from the apparently normal spleen of this bird was as follows. It was killed about eight weeks after inoculation and was found to be free from tuberculous disease. The second fowl, which had received only one injection of human tuberculous sputum (viz., on Nov. 25th, 1908), was killed June 25th, 1909. It was in perfect general condition. In the substance of the right pectoral muscle there was a narrow elongated focus of fibrous tissue, in the centre of which, at one spot, there was a softer, whitish material. The lesion was rubbed up with sterilised salt solution and injected into a guinea-pig. The spleen of the fowl (which to the naked eye, like all the other viscera, was normal) was rubbed up in salt solution, and the whole injected into the thigh of a guinea-pig. The first guinea-pig died July 13th; the necropsy showed no trace of disease at the site of the injection or elsewhere. The second animal was killed August 4th. The necropsy was absolutely negative.

The Inoculation and Feeding of White Rats with the Avian Tuberole Bacillus.

The wild rat occasionally suffers from a disease characterised by the formation of multiple granulomata of the skin and viscera, in which dense clusters of acid-fast bacilli are present. In this country the disease has been fully investigated by Dr. George Dean, although observations upon it had been previously published by Stepansky (1903) while working at plague in Odessa, and whose results were confirmed by Rabinowitch in Berlin. Dr. Dean was able to transmit the disease to black-and-white rats by subcutaneous and intraperitoneal injection of suspensions of the bacilli from the infected tissues, but was unsuccessful in his attempts to cultivate the micro-organism. In the latter particular, and in the marked density of the bacilli in the lesions, this disease recalls human leprosy; the closeness of the similarity is manifested, moreover, by its inoculability

only to other animals of the same species—i.e., to rats; for attempts to infect guinea-pigs, rabbits, mice, and macacus rhesus failed; and in man leprosy is transmitted only from one individual to another. After subcutaneous inoculation a local lesion in several instances ensued. The lesion consisted of a nodule containing a semi-caseous substance resembling that present in the skin of the naturally infected animals. The acid-fast bacilli are very numerous in these local lesions. The lymphatic glands in such cases, even at a distance from the lesion, were sometimes invaded by the bacilli. The most marked lesions, however, resulted from intraperitoneal injections.

Amongst tuberculous diseases the density of the bacilli is matched in the avian variety. In the various forms of avian tuberculosis the acid-fast bacilli are as thickly clustered as they are in this leproid disease of the rat. It was with the object of ascertaining whether the two conditions were the same that we injected a series of white rats with a pure culture of the avian bacillus, and also with the tuberculous spleen and liver of a pheasant dying from typical tuberculosis.

The Inoculation of White Rats with a Pure Culture of the Avian Tubercle Bacillus.

Five white rats were injected into the muscles at the root of the tail with a pure culture of the avian bacillus suspended in sterilised salt solution.

Rat 1. A rat was killed 11 days after inoculation. At the site of injection there was a lesion of about the size of a small pea, with a somewhat yellow centre. Smears made from the local lesion showed large numbers of acid-fast bacilli. The abdominal viscera presented no marks of disease. The lumbar gland of one side was slightly enlarged; microscopic sections of this showed foci of endothelial proliferation and giant cells; the giant cells held considerable numbers of tubercle bacilli.

Rat?.—A rat was killed 18 days after inoculation. At the root of the tail there was an intramuscular lesion, as in the previous experiment, but less extensive. Smears from this showed considerable numbers of tubercle bacilli. There was no disease of the lumbar glands or viscera.

Rat 3.—A rat was killed 100 days after inoculation. There was no local lesion at the site of inoculation and no disease of the lumbar glands or viscera.

Rats 4 and 5.—The remaining rats were killed 127 days (18 weeks) after inoculation. In one there was a small encapsulated intramuscular caseous mass at the right side of the root of the tail; smears from this showed considerable numbers of tubercle bacilli. The viscera presented no signs of disease. The second animal presented no local and no visceral lesions.

The Inoculation of White Rats with the Tuberculous Spleen and Liver of a Pheavant.

In the two following experiments a salt suspension of the tuberculous spleen and liver of a pheasant dying from tuberculosis was used as an injection, the inoculation being made into the root of the tail.

Rat 1.—One of the rats was killed 49 days (7 weeks) after inoculation. There was no local lesion and no disease of the viscera. The lumbar gland of the left side was enlarged, but without caseation; smears from the cut surface showed a very few bacilli.

Rat 2.—The second rat was killed 89 days (nearly 13 weeks) after inoculation. There was a small localised abscess, not caseous, in the muscles at the base of the tail. A smear from this showed numbers of polymorphonuclear leucocytes and giant cells, each kind of cell being full of tubercle bacilli. The lumbar glands were not enlarged; there was no disease of the viscera.

The Freeding of White Rats with the Diseased Organs of Tuberculous Birds.

Three white rats were fed with the tuberculous spleens and liver of three pheasants (received within a few days of one another) on Nov. 16th, 18th, 20th, 25th, and 26th, 1908. They consumed large quantities of the material with avidity.

Rat 1.—A rat was killed 58 days (8 weeks) after feeding. The intestine was slit up, washed, and minutely examined.

⁴ Journal of Hygiene, vol. v., No. 1, January, 1905.

⁵ The bacillus was from a subculture carried on from a strain kindly supplied to us by Professor Delépine, who raised it from a tuberculous fowl.

There was no trace of tuberculous disease within the intestine or on the peritoneal aspect. The viscera were normal.

Rat 2.—A rat was killed 98 days (14 weeks) after feeding. The intestine and stomach were slit up, washed, and carefully examined. There was no trace of disease in the mucosa or peritoneal coat and the viscera were normal.

Rat 3.—A rat was killed 125 days (18 weeks) after feeding. A close examination of the intestine revealed no disease of the mucosa or peritoneum. The viscera were normal.

Conglusion.

These various results show that the white rat is immune to the avian tubercle bacillus, whether the bacillus is experimentally injected (in pure culture or directly from the diseased viscera) or whether it is introduced in large quantities by the mouth.

ON THE USE OF RADIUM FOR LOCAL APPLICATION WITHIN THE BODY.

BY ALFRED C. JORDAN, M.D. CANTAB.,

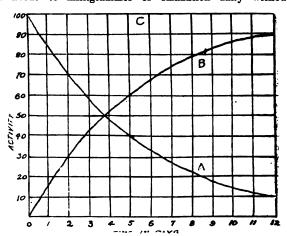

MEDICAL RADIOGRAPHER, GUY'S HOSPITAL, AND ROYAL HOSPITAL FOR DISEASES OF THE CHEST.

THE supply of radium is at present so small that the limits of its therapeutic usefulness have not yet been fully determined. Hitherto radium has usually been employed in the form of crystals of radium bromide. These crystals are contained either in a sealed glass tube or in a button with a covering of thin glass, aluminium, or mica. More recently they have been spread in a thin layer upon a flat surface and covered with a layer of varnish. Such buttons and spread preparations are suitable for application to the surface of the body.

Of the three types of radiation given off by radium (the alpha, beta, and gamma radiation) the view commonly accepted is that the gamma rays have a selective action, destroying diseased cells while leaving the normal cells intact, whereas the alpha and the soft beta rays are said to have a destructive action, destroying not only the diseased cells but also the normal cells. Much further investigation is required before this point can be finally settled. In the meantime it seems wise to accept the statement provisionally and to use means to prevent the alpha and soft beta rays from reaching the body. For this purpose a filter consisting of 1 millimetre thickness of lead is suitable.

The gamma radiation appears to consist of ether rays of the same kind as very penetrating X rays, and there will only be an advantage in applying radium as compared with the application of X rays if it be shown that the gamma rays have a more definite selective action than have the X rays. In the interior of the body—as, for instance, in the mouth, throat, cosophagus, rectum, and uterus—it is not possible to apply the X rays directly in most cases. In such cases there appears to be a very real indication for the use of radium, and the method to be described was devised for the purpose of carrying out this indication in practice. For this purpose I have been enabled to obtain radium emanation in sealed glass tubes. The emanation is obtained from a solution of 400 milligrammes of radium bromide. solution is kept in a flask to which is attached a Töpler air-pump. The air in the flask is kept partially exhausted, and whenever any radium is required the pump is worked until at the low pressure the solution commences to boil. Radium emanation is carried with the water vapour and residual traces of air into the tube leading out of the flask; this may then be collected in a small length of glass tubing inverted over a cup of mercury, and the tubing sealed up in the flame. Thus the original stock solution is never touched. The sealed glass tube containing the emanation behaves physically exactly like a similar tube containing crystals of radium bromide. All the forms of radiation are given off from it in exactly the same way: but there exists a great difference-viz, that the radio-activity of the emanation tube immediately begins to decay according to an exponential law as expressed in the accompanying curve (see figure), so that at the end of about four days it has lost half its radio-activity. The radio-active value of the emanation tube is determined when it is first sealed by means of an electroscope, measuring it by its |

gamma radiation against a standard preparation of radium bromide. By means of the curve it is then a simple matter to determine the exact strength of the emanation tube at any subsequent date. While the emanation in the sealed tube is decaying the original radium (which had lost an equivalent amount of radio-activity) is recovering. With a stock solution of 400 milligrammes of radium bromide it is possible to withdraw the equivalent of about 40 milligrammes of emanation daily without

Decay and recovery curves of radium emanation from "The Radioactive Substances" (W. Makower). International Scientific Series, vol. xcii., p. 149.

diminishing the value of the solution. If more than 40 milligrammes be removed daily then the stock solution loses strength, and the withdrawal of emanation must be discontinued for a few days to enable it to regain its full value.

I have had lead "compo" tubing made of suitable sizes, the wall of the metal being 1 millimetre in thickness in every case. Every glass tube of emanation is enclosed in a length of this tubing, the ends of the metal being closed down over the glass, rounded off, and welded up. All the soft beta rays are absorbed in this metal (the alpha rays are not able to penetrate the glass), while some of the hard beta rays and practically all the gamma rays are able to escape. The metal tubing is enclosed in a tube of rubber, the ends of which are closed by a silk ligature, a considerable length of silk being left attached to one end. The tube is then ready for insertion into the rectum or cervix uteri in a case of recurrent or inoperable carcinoma. A 10 milligramme tube may be left in situ indefinitely (say all night and through the greater part of the day) without fear of producing any destructive action on the normal tissues. In the case of a growth high up in the rectum or in the sigmoid flexure—i.e., beyond the reach of the finger—the "compo" tube containing the emanation tube may be placed within a long rectal tube of rubber, and in this way may be passed up to the required spot. In the case of the esophagus the compo-tubing containing the emanation is placed in a Symonds's tube or in a stomach tube, and the tubing is passed down to the required place. In this case the tube must be removed for the purpose of administering food to the patient. It is easy to make sure by an X ray examination that the tube lies at the required place.

It is true a glass tube containing crystals of radium bromide might be used in a similar manner, but there is a very obvious advantage in using sealed tubes of emanation, for there is considerable risk of losing a valuable tube of radium crystals if it be left in the rectum, while the loss of a tube of emanation involves nothing more serious than the loss of a fortnight's treatment. A further advantage is due to the fact that the whole length of the emanation tube is uniformly radio-active, while the crystals fall to one end of the tube. The cases in which I have applied this method have included recurrent carcinoma of the rectum, cervix uteri, esophagus, and floor of the mouth. Although it is too early to give detailed results I may say that the results so far obtained are promising. It is scarcely necessary to point out that the use of sealed glass tubes containing emanation is not in any sense comparable to the use of emanation by injection

into the blood-stream or by inhalation, both of which methods have been tried. The method I have described is exactly the same in its nature as the use of crystals of radium bromide in sealed tubes, while my method is far more convenient and does not involve the risk of losing valuable tubes of radium salts.

Considering the enormous energy given out by radium, and considering that the alpha rays possess about 100 times as much energy as the beta and gamma rays together, it is obviously a matter of great importance to decide whether it is not possible to make use of the alpha radiation in treatment. For this purpose the suggestion of Makower should be carried out. He points out 1 that "we have only to expose a negatively charged conductor, for example a wire, to the emanation in order to concentrate the maximum possible quantity of active deposit on its surface. It is thus possible, without any difficulty, to obtain surfaces whose activity per unit area is enormously greater than could be obtained by any other means." Needles thus rendered active could be inserted into the interior of malignant growths where they would be able to exert the whole of their energy. The activity of these needles decays very much more rapidly than is the case with the emanation; they decay to half value in about 20 minutes. At the end of this time they can be recharged and reinserted into another part of the growth. Electrodes of various forms could be charged and held in contact with localised growths e.g., in the larynx -for a suitable time, which must be determined by trial. I have not yet attempted to apply this method, which is necessarily experimental and requires the resources of a large institution. Weymouth-street, W.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A CASE OF ENURESIS WITH HYPER-METROPIA.

BY ALBERT H. FARDON, M.D. CANTAB., M.R.C.S. ENG.

ENURESIS in children has had many and varied pathological conditions put forward as a causal factor, but hypermetropia, as far as I know, has not yet ranked amongst them. The following case seemed to indicate that possibly it should do so, and may be of interest for that reason.

The patient was a girl, aged 7 years, who attended my outpatient department for lack of control over the bladder. Her mother stated that the child had been in the habit of wetting herself for more than a year, and every day she returned from school wet through. The condition was first noticed soon after she began to attend school. The trouble occurred only at day-time, and she never wetted the bed. She had gradually been getting worse, and at the time she came to me she would pass urine six or eight times a day-in fact, she did so whilst I was talking to her. She was always conscious at the time and was a perfectly intelligent child, and said that she was quite unable to prevent it although she tried hard. She had no local condition to explain the trouble, and the urine was quite normal. She had no suspicion of adenoids and had not suffered from worms. She was the younger of two children, the elder girl being quite healthy. One infant had died from "convulsions," but apart from that there was no history of epilepsy. She never complained of pain in passing urine, and was not examined for a calculus. The patient was treated in the ordinary way with belladonna for some weeks, with no improvement. Bromides were also given a trial. The fact that the enuresis was diurnal only, and also that the trouble started soon after she commenced her schooling, suggested to me that her eyes might be the source of the trouble, and I accordingly performed a retinoscopy under atropine and found that she was hypermetropic to the extent of over 5 D. She was ordered glasses for constant wear and no further medication. In 10 days the mother said that the child was much better, and a week later she had

been four complete days without wetting herself. She has been wearing her glasses for six weeks at the time of writing and is entirely free from her trouble.

County Hospital, Guildford.

AN UNUSUAL CASE OF H.EMO-PERICARDIUM.

BY A. J. WILLIAMSON, M.A., M.B., CH.B. ABERD., HOUSE SURGEON TO THE LIVERPOOL STANLEY HOSPITAL.

THE body of a man, aged 35 years, was brought to the Liverpool Stanley Hospital on the morning of Oct. 20th, 1909. He was a labourer, and according to the account received had fallen from a box a couple of feet high to the ground, where he continued to breathe in a stertorous manner for about 20 minutes when death supervened.

At the necropsy I found on opening the chest that the pericardium was greatly distended and that it projected well over to the right side of the sternum. It was found to contain about 18 ounces of well-formed blood-clot, and at the first glance it was rather difficult to locate the source of this effusion. The pericardium had a healthy appearance and there was no visible rupture of the heart. The organ itself was in a condition of well-marked fatty degeneration, the muscle being pale, flabby, and atonic. Beyond slight atheroma at the mouths of the coronary arteries these seemed to be in good condition. But when the organ was washed, in addition to two well-marked "milk spots," there were seen on its surface several small ecchymoses. These ecchymoses were situated on the right ventricle, and to a less extent on the left ventricle, and when sponged clean blood was seen flowing from the mouths of minute vessels in their centres. At the aortic valves some thickening was noted and the aorta was enlarged and atheromatous. There was no evidence of aneurysm. Congestion was present in the abdominal organs, which were in general very healthy. The liver showed signs of commencing fatty degeneration, and the stomach was large and contained the partly digested residue of a meal. The brain was perfectly healthy.

Death seems to have been caused by sudden stoppage of the heart from increasing pressure within the pericardium, and the causative effusion followed the rupture of several small cardiac veins which were in a condition of congestion from a feebly acting left ventricle.

ROYAL SOCIETY OF MEDICINE.

MEDICAL SECTION.

The Role of Fats in the Treatment of Disorders of the Stomach.

A MEETING of this section was held on Nov. 23rd, Dr. J MITCHELL BRUCE being in the chair.

Dr. F. CRAVEN MOORE and Dr. R. L. FERGUSON contributed a communication on the Rôle of Fats in the Treatment of Disorders of the Stomach, which was read by Dr. Craven Moore, and which is published in full on p. 1737.

Dr. A. F. HERTZ said that, in his experience, the administration of olive oil before meals was not sufficient to relieve symptoms. He found that the best results were obtained by placing patients on an exclusive diet of olive oil.

Dr. R. SAUNDBY did not consider that the use of clive oil was necessary in order to relieve pain. He had observed that when these patients were put to bed pain disappeared. He maintained that in cases of hyperacidity a useful treatment was half a pint of infusion of hops taken before going to bed.

Dr. R. HUTCHISON pointed out that many patients with hyperacidity had a repugnance to taking oil; he had known patients who preferred to suffer the pain of the condition rather than take oil. He suggested that the treatment by oil might be limited in its application.

Dr. FERGUSON and Dr. MOORE then replied and the meeting ended.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

The Laboratory Diagnosis of Syphilis.

A MEETING of this society was held on Dec. 3rd, Dr. NEVILLE T. WOOD, the President, being in the chair.

Mr. Hugh W. Bayly read a paper on "Laboratory Methods for the Diagnosis of Syphilis." In Part I., Serum Diagnosis, he discussed the technique and rationale of the Wassermann and Bordet-Gengou reactions and described the terms commonly employed. Part II. Micro-biology.-The ultra-microscope, or reflecting immersion condenser, and the technique for its use were described. It was stated that the treponema pallidum can be demonstrated in practically every early untreated chancre and is also found in papular rash and mucous plaques. It appears as an extremely fine spiral from 5-25 μ long, with very regular and closely set spirals. Number of spirals range from 5-25. Distilled water is the best medium in which to examine them. Giant forms may be seen when examined in serum, and in this medium the movements are more active and last longer than in water. The movements consist of bending, snake-like movements, local wave contraction. Viscosity develops as organism becomes less motile. Agglutination occurs in serum only. The older the infection the greater the tendency to clump (auto-agglutination). Diagrams were shown for differential diagnosis of "spirochæta refringens," "spirochæta balanitidis," &c. Part III. Inoculation experiments.—Path of infection and mode of entrance discussed; small superficial erosions the most dangerous. Incubation: The more resistant the animal the shorter the incubation period. In apes positive inoculation obtained with material from the bone-marrow. spleen, and, much less frequently, testicle and lymphatic glands. In man: Positive inoculation obtained from wellmarked secondary syphilis. Virus: Attenuated by passage through apes. Prophylactic measures discussed. Conclusions: (1) That syphilitic infection is easily preventable; (2) that such infection can be diagnosed with certainty on the first appearance of a primary sore by means of the microscope; (3) that the earlier that the treatment is begun the better for the patient; (4) that a positive Wassermann, in the absence of a few diseases, is pathognomonic of syphilis; (5) that the Wassermann reaction forms a very useful guide to treatment, and that antisyphilitic treatment should be continued till a succession of negative results are obtained; (6) that the blood should be examined every six months for a couple of years at least after the first negative reaction is recorded.

Colonel F. J. Lambkin, R.A.M.C., said that for a year all the syphilitic cases admitted in the Rochester Row Hospital had been subjected to Wassermann's reaction. He quite agreed as to the value both for the treatment and diagnosis and quoted cases. He mentioned that the cases treated with arylarsenates had shown no toxic symptoms.

Captain Harrison, R.A.M.C., had carried out the test in Rochester Row Hospital and confirmed all that Colonel Lambkin had said. He hoped that much might be learnt and done for the treatment, &c., of syphilis by the use of the Wassermann test in the army on account of the efficient system of supervision which is required in these cases. He thought it advisable in the case of negative reaction to repeat the test with untreated patients' serum.

Mr. J. ERNEST LANE said that he agreed with the value of Wassermann's test. It would allow early treatment and at the same time avoid the treatment of non-syphilitics with prolonged courses of mercury, which had undoubtedly occurred. He spoke as to the toxic effects of the arylargeners.

Mr. C. GIBBS agreed with the great advance in syphilology due to Wassermann's reaction. He also spoke on the arylarsenate question.

Mr. REGINALD H. HAYES hoped that the test would settle the relative values of the modes of administering mercury.

Mr. J. E. R. McDonach said that there was a tendency for the test to be negative in undoubted syphilitic cases whilst taking mercury. He pointed out the great use of the test in women who aborted. He had found a tendency for the test to remain permanently positive in the cases of

children suffering from congenital syphilis, however long they were treated with mercury. He mentioned some causes of failure of the test and how to remedy them.

Dr. F. E. BATTEN spoke and Mr. BAYLY replied.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases.—Therapeutics of Radium.—Dyspepsia and Early Tuberoulosis in Children.

A MEETING of this society was held on Dec. 1st, Dr. BYROM BRAMWELL, the President, being in the chair.

The PRESIDENT exhibited a man, unmarried, aged 32 years, who suffered from Preataxic Tabes. The case was both of theoretical and practical interest as these tabetic attacks of gastric and intestinal crises were often mistaken in practice for other diseases. The man had been operated on for appendicitis two years ago, and since then he affirmed he had been subject to very severe attacks of abdominal pain. On examination nothing abnormal could be made out in the abdomen and it was at first thought that the attacks were due to post-operative adhesions. On further inquiry, however, it was discovered that the man had suffered from similar attacks for six months previous to his operation. He had never had lightning pains or ataxia, but his knee and Achilles jerks were completely absent; the Argyll-Robertson phenomenon was present. His blood showed marked lymphocytosis (400 in each field) and the Wassermann test was He admitted having contracted syphilis nine years ago. The attacks, which were very severe, occurred about once in six weeks and were accompanied by tenesmus. He was being treated by X rays and the patient felt himself to be better.

Mr. A. A. Scot Skirving showed a man who illustrated certain Defects of Memory after operation for Middle Meningeal Hæmorrhage. The patient fell downstairs five months ago and was unconscious when admitted to the infirmary. On examination there were no symptoms of compression, the pupils were equal, and paralysis was absent. One hour later, however, it was found that there was right-sided paralysis and the left pupil was double the size of the right. Hæmorrhage from the left middle meningeal artery was diagnosed. At the operation a fairly large clot was removed. By next day the paralysis had gone, but the patient remained perfectly unconscious for nearly three weeks. He then began to recover, but for many months subsequently marked weakness in the right arm and hand remained with slurring of the speech, especially in words with the letter "s," and loss of memory. He was formerly a clerk, but could not perform simple sums for nearly 18 months after his accident. At present he has greatly improved and his mental faculties and speech were returning.

Dr. Francis D. Boyd exhibited a man to illustrate the benefit of a Salt-free Diet in certain forms of (Edema. The patient suffered from a syphilitic ulcer on the forehead. When admitted to the ward he was perfectly waterlogged and the ædema extended up to the shoulder-blades. The excretion of urine was very scanty, and especially the chloride excretion. He was put on a varied diet (meat, eggs, &c.) but one free from sodium chloride, and immediately there was an enormous diuresis with great loss in weight. He was discharged almost well, but on resuming his ordinary diet his diseased condition soon returned. On placing him again on salt-free food he rapidly improved and was at

present perfectly well.

Professor H. ALENIS THOMSON exhibited a boy, aged 11 years, in whom, on account of a Periosteal Sarcoma of the Right Humerus, the middle third of the shaft was resected and a portion of the fibula inserted in its place. Formerly the only treatment for such a disease was amputation, but the history almost always was that the patient died from recurrence. At first excision was only employed for the less malignant forms, but it seemed only right to give the boy the chance of recovery in this case. The operation was performed three months ago. The tumour, with 3 inches of bone, was resected, and those parts of the muscle which were infiltrated were also removed. Unfortunately the musculo-spiral nerve was sacrificed. About 5 inches of the boy's left fibula, together with its periosteum, was excised, and the ends having been

sharpened they were jammed into the cut ends of the humerus. The wounds were quite healed and there seemed to be firm union between the bones. The cut ends of the musculo-spiral nerve were spliced into the musculo-cutaneous nerve and restoration of function was hoped for. Treatment by X rays was being carried out in order to prevent recurrence of the growth if possible.

Dr. JAMES RITCHIE, jun., gave a demonstration of Wassermann's reaction.

Dr. DAWSON TURNER read a paper on the Use and Effects of Radium, and illustrated it by patients and lantern slides. The paper will be published in a future number of THE LANCET

Dr. A. DINGWALL FORDYCE read a paper on the Differential Diagnosis and Treatment of a common form of Dyspepsia and of Early Tuberculous Infection in Children, in the course of which he said: The introduction within recent years of new methods and new tests has conduced to greater precision in diagnosis, and, through the recognition and differentiation of various conditions in their early stages, has been of value in rendering possible early active treatment. There is considerable difficulty in certain cases in children in ascertaining whether the symptom-complex is due to a chronic digestive or metabolic disorder, or whether a chronic infective condition-e.g., tubercle-lies at the root of the evil. The cases here considered are marked by vagueness in personal history and in symptoms, all have very chronic symptoms, mostly gastro-intestinal, there are no definite abnormal physical signs, and the children are going about, are comparatively well, and have approximately normal temperatures. Accurate and prompt diagnosis is essential to permit of active treatment. The special points in the diagnosis are: 1. The capacity of digesting fat. This capacity is considerable in cases of early tuberculous infection whereas it is markedly diminished in dyspepsia. 2. The reaction to tuberculin tests. Pirquet's cutaneous tuberculin reaction is of great value in diagnosing cases of this kind. A positive reaction to either the human or bovine form of tuberculin is a call for active antitubercular treatment. 3. The quantitative and qualitative estimation of the sulphates in the urine. 4. The opsonic index. Most of the tuberculous cases of which I speak are those of glandular tuberculosis. The treatment in the two classes of cases varies considerably: in chronic dyspepsia, markedly reduced diet, &c.; in early tubercle infection, free diet, fresh air, the prevention of sources of glandular irritation and infection, and tuberculin. My own impressions as regards the administration of tuberculin in obviously glandular infections—mainly abdominal or cervical glands -or in cases which by the previous methods of diagnosis I have diagnosed as latent tuberculosis, and I think these are chiefly glandular, are: 1. That this treatment is very unsafe when large doses are employed or when the temperature is unsteady. 2. That it is quite safe in the minute doses hereafter mentioned, when commenced with a practically normal temperature and when the patient is kept under observation. 3. That in many cases tuberculin treatment appears to have no definite effect upon the condition one way or another. 4. That in cases in which treatment by rest, climate, feeding, and careful nursing can be employed, improvement by these means alone is usually so marked that it is impossible to attribute to tuberculin, when given in these cases, its due meed of praise or to judge whether it takes any part whatever in the improvement. 5. That, however, when treatment by rest, climate, feeding, and careful nursing cannot be properly adopted, tuberculin is often of very marked value. These are the cases which otherwise do badly, and tuberculin treatment is, with them, of the greatest importance. 6. That T.R. is, as a rule, preferable to P.T.R. 7. That for routine use the method of hypodermic injection is greatly superior to that of oral administration—the effect of giving tuberculin by the mouth varies very much. These impressions are derived from the treatment of about 100 cases during the past three years. At the commencement I used the opsonic index as a guide, but early found it impossible and, I think, unnecessary to take the index in selected cases such as these. The condition of the temperature is, I think, a sufficient guide for the initial administration and the clinical symptoms thereafter in relation to each injection. The forms of tuberculin I have used have been Koch's new tuberculin, T.R., and the

corresponding bovine tuberculin, P.T.R. The two varieties I originally employed in order to determine their varying results in cases showing different reactions to von Pirquet's test with human and bovine tuberculin. I have come to the conclusion, however, that, no matter to which strain of bacillus von Pirquet's reaction is positive, T.R. is the tuberculin of the greater therapeutic value. culin was given hypodermically and by the mouth. By the mouth the doses I gave varied from 1-1000th of a milligramme to 1-250th of a milligramme and the results I considered very disappointing; only very occasionally was any satisfactory result noticeable. By hypodermic injection the initial dose varied from 1-10000th of a milligramme to an infant 9 months old, to 1-3000th of a milligramme to a child aged 12 years. The injections were repeated weekly or fortnightly, and the dose increased at long intervals and by very minute amounts, the rapidity and amount of increase desirable being gauged by the clinical condition. In all cases diminished vitality or health-apparent in any manner whatever—during the few days following an injection was considered a sign, either to diminish the dose or increase the intervals between doses, the conditions aimed at being that after each injection the child should continue steady improvement or show a step in advance. In several instances a child while under tuberculin treatment had apparently attained sound health; the tuberculin treatment was stopped for two or three months, the child relapsed, only again to improve on the renewal of the injections. Dr. JOHN W. SIMPSON thought that it was almost impossible to diagnose chronic intestinal catarrh from tuberculosis of the intestine in children and was of opinion that reaction to the tuberculin test was not of very much value because it could be obtained in perfectly healthy children.—Dr. D. CHALMERS WATSON said that the same difficulty in diagnosis existed in young adults as in children. He drew attention to the value of thyroid in tuberculous cases.—Dr. J. S. FOWLER and Dr. BOYD also took part in the discussion.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Operative Treatment of Fracture.

A MEETING of this section was held on Nov. 19th, Mr. JOHN LENTAIGNE, the President, being in the chair.

The President, in his introductory remarks, commented on the falling off in the attendances at the meetings, although during the past session many valuable papers had been read and many cases of extreme interest had been exhibited.

Mr. R. Lane JOYNT read a paper on the Operative Treatment of Fracture. He said that X ray examination of united fractures of the femur which had been treated by the common methods showed in many cases an amount of deformity which was little short of that seen in a number of museum specimens which were formerly regarded as examples of mal-union. The functional result in most of these cases The only way in which shortening could be was very bad. prevented and the fragments got into perfect line was by operation. Even when complete asepsis was not obtained suppuration was usually slight, and the results were much better than when the older methods were employed. A striking feature after the fixation of the fragments was the rapid disappearance of pain. He then described minutely the details of the operation for wiring, and of that in which Lane's steel plates were used. He looked upon Parkhill's method as being superseded in some cases; but there were others, notably where there was a compound fracture of the tibia with excessive suppuration and necrosed bone, in which it would be folly to attempt to suture or screw with Lane's plates or to use wire.

Mr. W. I. DE C. WHEELER read a paper on the Operative Treatment of Fracture and showed four cases where simple treatment had failed, but continuity and union were afterwards established by the use of screws and metal plates. In one case the operation was performed 3½ months after a compound fracture of the tibia and fibula which failed to unite, so that the limb was rendered useless. After operation complete union was obtained, the wound, which was partially open, healing over six screws holding two plates. The

fibula was wired. A second patient presented himself for treatment 11 months after the accident for a false joint of the tibia and an ununited fibula following simple fracture. Firm union was obtained after excision of the joint, and the introduction of screws, wire, and plates. The third case involved the surgical neck of the humerus, with a marked outward tilt of the upper fragment; the upper end of the lower fragment was embedded in the muscles under the coracoid process. A fortnight's treatment under the guidance of X rays failed to reduce the deformity. A single plate supported by an encircling wire was introduced to hold the fragments in position. The last case was that of a child, aged four years, who sustained a long spiral oblique fracture of the femur. Extension under an anæsthetic and immobilisation of the fracture in plaster-of-Paris failed to reduce the overlapping of the bones. Finally, an operation was performed, two plates and three encircling wires being introduced. All the wounds healed by first intention.

The PRESIDENT of the Academy (Sir CHARLES BALL) said that Mr. Joynt had given a very good demonstration of the application of practical mechanics to surgery. The instruments that had been shown were excellent on account of their size and capability, whereas the majority of instruments used for bone surgery were small and incapable. He had often speculated as to how the long American spindle turnscrew could take out a screw that could not be touched with a short one, and until that night he had never heard anything

like a reasonable explanation.

Sir Thomas Myles said that he had in 1884 brought forward a suggestion for the operative treatment of fractures. A quarter of a century had passed since then, and 30 years since the introduction of antiseptic surgery, and yet it was only to-day that the operative treatment of fractures was becoming general. Mr. Joynt had shown that, even when suppuration ensued, if proper provision was made for drainage, the results of operative treatment were decidedly better than those of non-operative treatment, no matter how well carried out. Most of the surgeons present had, however, tried the method of wiring, the method of the Lane plates and the Parkhill method, which was capable of being used in many cases with less disturbance than the method discussed that night.

Mr. R. C. B. MAUNSELL cited cases in which he had got good results by wiring, but with great difficulty, whereas when he had used screws and plates in identical cases the

operation was not at all a hard one.

The PRESIDENT said that if an operation was to be performed in a case of fracture the sconer it was done the better; delay added to the difficulty of the operation and interfered with the beneficial result. He had found the Parkhill clamp difficult to employ; it left several holes in the skin and there was always an increased danger of sepsis.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.-A meeting of this society was held on Dec. 1st, Dr. A. Fulton, the President, being in the chair.—Dr. F. H. Jacob showed an unusual case of Pernicious Anemia with microscopic specimens of the patient's blood. Dr. Jacob also read a few notes on a case of Delayed Chloroform Poisoning. The patient, aged 12 years, suddenly became maniscal 36 hours after the administration of chloroform, and very closely simulated a case of acute septic meningitis. A lumbar puncture revealed increased cerebro-spinal pressure but nothing else. Microscope slides showing fatty degeneration with areas of necrosis of the liver were shown.— Mr. A. R. Anderson read a paper on Some Remarks on the Treatment of Uterine Cancer. He considered first the possibilities of a cure and called a case "a cure" which was free from recurrence five years after the operation. The author maintained that the majority of cases can be cured if operated upon early enough and that the prospects of a cure are better than in cancer of the breast. The operation of choice was abdominal hysterectomy, which was completely superseding vaginal hysterectomy. As regards the operability of a case, all early cases, where the disease was confined to the cervix and the uterus was moveable and the broad ligaments were free, should be operated upon. But in his hospital practice only 1 in every 8 cases was thus favourable. Cases where the rectum and bladder were nvolved were clearly inoperable. By far the larger number of cases came within the intermediate doubtful

area. Mr. Anderson then read notes on a series of 20 such doubtful cases upon which he had operated in 1897 and the four succeeding years. A mortality of 30 per cent. in this series induced him to advise against operating in these doubtful cases. But Wertheim's encouraging figures in 1905-induced him to follow his lead with gratifying results. Finally, Mr. Anderson uttered a plea for the more early recognition of the disease and the more frequent vaginal examination by medical men.—The President, Dr. J. Watson, Dr. Purves, Dr. C. H. Cattle, Mr. A. M. Webber, and Dr. G. A. Coulby took part in the discussion.

LIVERPOOL MEDICAL INSTITUTION.—A meeting of this society was held on Nov. 18th, Mr. T. H. Bickerton, the President, being in the chair.—Mr. Thomas Guthrie read a note on the Removal of a Tooth-plate which had remained Impacted in the (Esophagus for three weeks by means of Brüning's (Esophagoscope. The instrument was demonstrated, and radiographs by Mr. C. Thurstan Holland showing the tooth-plate in the esophagus were exhibited.-The note was discussed by the President, Dr. A. G. Gullan, Dr. T. R. Bradshaw, Mr. R. A. Bickersteth, and Mr. E. M. Stockdale.—Dr. W. B. Warrington read a note on the Results of Treatment in some of the Grave Cases of Diabetes Mellitus. The note was illustrated by lantern slides of charts showing various diets and the results of usage.—It was discussed by the President, Dr. Bradshaw, and Dr. J. Hill Abram. - Dr. F. H. Barendt showed a child suffering from Erythema Multiforme. -Dr. Nathan Raw showed the Brain of a child, aged 12½ years, dead from Hæmorrhage into the Right Lateral Ventricle .-Dr. Henry Briggs read a paper on the Restoration of the-Female Pelvic Floor by Operation or an Extended Perineorrhaphy. The object of the paper was to urge, on anatomical and clinical evidence, that: (a) reparable damage (mainly obstetrical) to the pelvic floor calls for a prompt remedy during the parous period of life; (b) irreparable atrophy of the pelvic floor is a consequence of the still too frequent postponement of radical operative treatment until the post-parous period of life; (c) modern advances in anatomical knowledge and in surgical methods justify an earlier restoration of the pelvic floor; (d) loss of tissue by excision of any portion of the vaginal walls is unnecessary and no longer an argument against operation during the parous period of life; and (e) a safe, simple, and effective operation was described.—The paper was discussed by the President and Dr. J. E. Gemmell, and Dr. Briggs replied.

ULSTER MEDICAL SOCIETY.—A meeting this society was held on Dec. 2nd, Dr. J. J. Austin, the President, being in the chair.—Dr. H. L. McKisack showed a man with Wasting of Certain Muscles of the Neck, Chest, and Arms as an example of Erb's Progressive Muscular Juvenile Atrophy. -Mr. Robert Campbell read a paper on the Treatment of Exophthalmic Goitre, dealing very fully with the suggested medical and surgical treatment, and giving full details of his own cases, in which the had, successfully and with good after-results, removed a portion of the thyroid gland. An interesting discussion followed.—Dr. T. Houston and Dr. J. Rankingave a demonstration of the laboratory method of diagnosing syphilis following Fleming's modification of Wassermann's reaction. They also supplied a series of interesting printed tables showing:—(1) Cases with Definite History and Definite Syphilitic Lesions at the Time of Examination; (2) cases with Definite History of Syphilis; (3) Parasyphilitics; (4) cases with other Diseases; (5) Normal Controls.—Dr. J. A. Sinton showed preparations of the Spirochæta Pallida. -Sir John Byers, in the name of the large audience present, thanked Dr. Houston and Dr. Rankin for their extremely interesting piece of research work, which reflected the greatest credit on the clinical side of the Belfast Medical School.

NEWCASTLE-UPON-TYNE CLINICAL SOCIETY.—A meeting of this society was held on Dec. 2nd, Mr. J. W. Leech, the President, being in the chair. The following cases were shown: Dr. T. M. Allison: (1) A case of Fibroid Phthisis with marked dislocation of the heart; and (2) a case of Oystic Kidney.—Dr. G. Foggin: Some cases of Albinism.—Dr. D. W. Patterson: A case of Morphea.—Dr. G. Hall: A case of "Acute Ataxy" occurring with a pneumonia in a child aged 3 years.—Dr. A. Parkin: A case of Mucous Colitis.—Mr. John Clay read a paper on an Irrigation Urethroscope

—Dr. F. C. Pybus read a paper on Appendicostomy as a Surgical Procedure. The speaker dilated on the technique of the operation, contrasting its results from the points of view of treatment and desirability with colostomy in the same region. Later he outlined the various conditions both above and below the appendix which were improved and cured by the operation.—The discussion was postponed to the next meeting.—Dr. W. T. Sewell then gave an Historic Review of Serum and Vaccine Treatment. In an interesting survey of the whole of the history of such treatment he traced the various steps of evolution in the methods from the earliest times right up to and including the processes involved in the modern method of vaccines.

Reviews and Notices of Books.

The Life of Sir William Broadbent, Bart., K. C. V. O., F.R.S. Edited by his daughter, M. E. BROADBENT. London: John Murray. 1909. Pp. 306. Price 10s. 6d.

THOSE who only knew Sir William Broadbent in his days of prosperity can hardly picture him as a man of small beginnings and hard struggles, but the simple annals which lie before us tell us in plain and ungarnished language—often, indeed, in his own words—that his ultimate triumph was well deserved and honestly won. In the preface to these memoirs the writer tells us that "no one can be more conscious than I myself of the deficiencies of this attempt to convey an impression of my father's life; but as a sketch may sometimes be more suggestive than a finished picture, so it is hoped that the portrait of him which emerges from the record of his own words and actions may be one which those who knew him will recognise and welcome as adding to their understanding of his character, while those to whom he is but a name may accept it as faithful within its limitations." In our opinion the picture has been well and faithfully drawn. Moreover, it portrays him as a man no less loveable in his private life than he was great in his professional capacity. As we read the early chapters of his life it is the indomitable pluck and determination of the ambitious young Yorkshireman which arouse our admiration, and which may well put heart and courage into many a young medical man now struggling along the same thorny path.

As a boy William Broadbent was educated at a day school in his native village of Longwood, whence he proceeded to Huddersfield College as a weekly boarder. At the latter institution he distinguished himself by winning several valuable prizes, but at the early age of 15 he bade farewell to school life and entered upon a business career. Shortly afterwards, however, in deference to his personal wishes to enter the medical profession, he became apprenticed for five years to his uncle, who was in practice in Manchester. In spite of the hard and anxious work which this apprenticeship entailed, it appears that young Broadbent found time and energy to attend lectures at the medical school in Manchester and to acquire the necessary knowledge for passing with distinction his professional examinations both at the Colleges and the University of London. His original intention was then to take up an appointment as house surgeon and subsequently to settle in practice in Huddersfield, but he failed in every application that he made, and was greatly discouraged and perplexed by such a continued series of disappointments. These initial rebuffs were the determining point in his career, for they led immediately to a step of the utmost importance, for he went to Paris without delay. Paris at this time was the chief centre of medical science in Europe, and coming into association with such teachers as Trousseau, Desmarres, Rayer, Ricord, and Piorry, it is impossible to exaggerate

the influence that such minds must have exercised on a young man of Broadbent's narrow and provincial experiences; indeed, it is not difficult to trace these influences on his character as a man, and in his scientific work as a physician. Moreover, it is highly probable that the first germs of his famous hypothesis in the bilateral association of the higher nerve centres fructified in the genial medium of the Salpêtrière. Broadbent's later successes, his Fellowship of the Royal Society, his work on the heart and on the pulse, his appointment as physician-in-ordinary to the Prince of Wales, his Baronetcy, and his work at St. Mary's, are still fresh in the memory of contemporary medical men and were recorded in these columns at the time of his lamented death. It is, however, as the clinical physician that Broadbent deserves best to be remembered. His powers of diagnosis and his capacity for forming an accurate prognosis were equalled by few physicians of his time; but on these points his memoirs are regrettably, but perhaps necessarily, silent.

In reading Sir William Broadbent's life it must occur to all those who only knew him in a professional capacity that his path would have been smoother if he had been less downright in his methods. Sir William Broadbent disdained to fight with the velvet glove. Neither had he the gift of tongues to round off the edges and asperities of his honest convictions. But in the annals of medicine he will live as one of the great English clinicians. This pleasant little memoir will be a delightful souvenir to those who personally had the honour of his acquaintance.

Archives of the Middlesex Hospital. Vol. XV. The Eighth Report from the Cancer Research Laboratories. London: Macmillan and Co. 1909. Pp. 204.

This volume opens with tabulated synopses of the postmortem examinations and operations in cases of malignant disease at the Middlesex Hospital during the year 1908, with records of the results of microscopical examination. Statistical studies of the cases of malignant disease of the cervix uteri based on the records of the Middlesex Hospital from 1904 to 1908, by Dr. H. MacCormac, and of malignant disease of the breast for the same period by Dr. H. Beckton, form a continuation of previous studies published in the Archives. Dr. Helen Chambers contributes an interesting paper on Malignant Disease of the Thyroid Gland. She concludes that the diagnosis between an innocent and a malignant tumour of the thyroid is often extremely difficult, and maintains that only those cases are to be regarded as malignant in which infiltration of surrounding tissues occurs. Apart from this evidence of infiltration, tumours other than sarcomata cannot be diagnosed as malignant from their histological structure alone. She states that carcinoma of the thyroid often pursues a very protracted course. Dr. Bryden Glendinning contributes a paper on Primary Malignant Disease of the Ovary, comprising a statistical study of 41 cases of primary carcinoma of the ovary, 16 cases of primary sarcoma, and 50 cases of papilliferous cystadenoma. Dr. Hector A. Colwell, in an interesting study of the erepsin in the tissues in malignant disease, finds that the ereptic values of tissues from cases which are the subject of serious and chronic organic disease tend to be lower than the normal, and that malignant disease conforms to this general rule. In a further contribution in collaboration with Dr. MacCormac on the ereptic power of the tissues of normal and cancerous mice, the results obtained seemed to suggest a slightly higher ereptic value in the tissues of mice harbouring a tumour than in the normal mice. Dr. J. C. Mottram describes a spectroscopic method for the quantitative analysis of the tissues for potassium and sodium. Dr. W. S. Lazarus-Barlow deals with the influence of carcinomatous and non-carcinomatous tissues upon electroscopic leak—a research which forms part

of this inquiry into the evidence as to whether there is any connexion between radio-activity and the carcinomatous process. He also records some experiments made in conjunction with Dr. Victor Bonney on the influence of radioactivity on the division of animal cells. The cells employed were the ova of the Ascaris megalocephala of the horse. The results obtained from X rays, radium, thorium, and uranium In small doses these substances caused were twofold. division to proceed at a faster rate than normal, whereas in large doses an inhibitory effect was obtained leading to total arrest of development in some instances. Sometimes monstrosities and irregular divisions were obtained. Another paper by Dr. Lazarus-Barlow and Dr. Colwell deals with the influence of atomic weight and valency upon the radio-activity of uranium and thorium compounds. Dr. MacCormac in a preliminary communication describes the power possessed by certain micro-organisms, notably staphylococcus pyogenes aureus and albus, bacillus diphtheriæ and bacillus tuberculosis, to affect a photographic plate in the dark. Dr. Beckton, in a paper on the granules in cells of normal tissues and new growths, states that in malignant new growths granules tend to disappear or are absent from the particular type of cells involved. Mr. C. W. Rowntree discusses the histology of X ray dermatitis in an interesting paper. Some experiments on the action of certain animal and other substances on the development of the ova of Ascaris megalocephala are described by Dr. Lazarus-Barlow and Mr. Somerville Hastings.

As a record of laborious work in the endeavour to throw light on the complex problem of the genesis of malignant disease this volume is worthy of high commendation.

Text-book of Anatomy. Edited by D. J. CUNNINGHAM, F.R S., Professor of Anatomy, University of Edinburgh. Third edition. London: Hodder and Stoughton; Oxford: Henry Frowde. 1909. Pp. 1427. 936 illustrations. Price 31s. 6d.

THE preparation of this edition of his well-known text-book was the last task of Professor Cunningham's life; he died a few days after he drafted its preface. He was not only a master-anatomist, he was its master-expositor; he had, beyond all cavil, the most gifted pen of modern British anatomists. He was a voluminous writer, but of all his works it is most likely with this text-book that his name will pass onwards amongst medical men. Only three chapters of it are actually written by himself-those on the brain and spinal cord, on the respiratory system, and on the ductless glands—but it is not too much to say that there is not a page of the book that does not reflect his influence, his precision, and his kindly spirit. This is naturally the case, for his collaborators were pupils of his own or of his master, Sir William Turner. There is no better text-book of anatomy in the English language than this product of the Edinburgh school; indeed, in many respects it is the best book.

Of the 14 sections into which this work is divided only two have undergone alteration for the present edition—the section on Osteology by Professor Arthur Thomson of Oxford University, and that by Professor A. M. Paterson, of Liverpool University, on Myology. The parts by the editor are unchanged; the Digestive System by the late Professor Ambrose Birmingham, the Urino-genital System by Professor A. F. Dixon, the section dealing with Joints by Professor D. Hepburn, the Organs of Sense and the Integument by Professor R Howden, the chapters on Embryology and the Vascular System by Professor A. H. Young, now unfortunately withdrawn from anatomy, and by Professor A. Robinson, now of Edinburgh University, and the chapter on Surface and Surgical Anatomy by Mr. Harold J. Stiles all remain practically as they were in the edition last reviewed by us.

The chapter on Osteology has undergone revision and extension. Illustrations have been added, showing centres of ossification as seen in radiograms; the articular surfaces of the bones have been emphasised by the use of colour; and areas of muscular attachment have been shown on specially drawn figures. In an appendix inserted at the end of the section Professor Thomson has given a most useful summary of the variations of the skeleton, of the terms and methods used in physical anthropology, and of the various problems concerning the morphology of the skull and skeleton. In only his section of the book are references given to recent or, indeed, to any literature. In a book of this size and standard the senior student has a right to expect guidance as to literature. The alterations in the chapter on Myology are connected chiefly with the introduction of new illustrations, and to these must be extended the very highest praise. They are artistic, truthful, and yet diagrammatic enough to convey the most essential features. The description of the pelvic fascia has been altered; but in spite of the fact that Professor Paterson is our leading authority on this complicated structure it cannot yet be said to be simple and easy of understanding.

In the sections that have been rewritten the nomenclature proposed by the Basle committee has been adopted as far as is possible. We are glad to note from the preface that the late Professor Cunningham was not altogether convinced that the adoption of the Basle terminology, which is being forced upon medical students in many parts of the world, especially America, was altogether advantageous for British anatomy. We are certain it is not. Many of the proposed terms are clumsy and unpractical. If we adopt this method of naming structures the anterior layer of the triangular ligament becomes the fascia diaphragmatis urogenitalis inferior, the internal arcuate ligament the arous lumbo-costalis medialis, the trapezoid of the wrist the cs multangulum minus, clumsier terms which give an advantage to no one.

We wish this text-book every success. In the preparation of the new illustrations no expense has been spared.

LIBRARY TABLE.

The Practical Medicine Series. Comprising 10 volumes on the Year's Progress in Medicine and Surgery. Vol. II.: General Surgery. Edited by John B. Murphy, A.M., M.D., LL.D., Professor of Surgery in the Northwestern University, Chicago. Chicago: The Year Book Publishers. Series 1909. Glasgow: Gillies and Co. Pp. 617. Price 8s.—The rapid expansion of surgery makes it practically impossible for the surgeon to be fully conversant with the most recent advances in the science unless he is able to refer to one of the several valuable annuals in which the progress of medical science is recorded. This volume is, we believe. the only one in the English language which is devoted only to surgery, and under the able editorship of Professor Murphy it is sure to be representative and accurate. It is true that many points suggest themselves for criticism, and here and there we consider that the material has hardly been adequately digested, but we appreciate the difficulty of dealing with such a large amount of added knowledge. The editor is wise in commenting on some of the new operations suggested, but it would have enhanced the value of the work if we had been provided with more of these comments from his pen. It is sometimes difficult for the reader to form an exact idea of the value of any suggested change from the necessarily short account presented to him in an annual, and therefore we should like to have had the opinion of Professor Murphy on these points. A good many illustrations are contained in this useful book.

Guide to Promotion for Non-Commissioned Officers (Corporal to Staff-Sergeant) and Men of the Royal Army Medical Corps, with Appendix on Hints to Young N.C.O's on Clerical and Other Duties in a Military Hospital. Compiled by Captain S. T. BEGGS, M.B. R.U.I., Royal Army Medical Corps (Reserve of Officers). Second edition. London: Gale and Polden, Limited, 1909. Illustrated, Pp. 380. Price 3s. 6d. net.—The favourable reception accorded to the first edition of this book having fully realised the hope expressed by the compiler that the guide should fulfil a useful purpose in the Royal Army Medical Corps and induce men to go in for promotion, he has accordingly issued a second edition. Great care has apparently been taken in bringing all matter up to date in accordance with the latest regulations, official text-books, and army orders, all of which have been strictly adhered to. New matter has also been added to make the guide applicable for the subjects connected with promotion to staff-sergeant, and a new section is embodied dealing with semaphore signalling, which is now authorised as part of the instruction of the Royal Army Medical Corps in field training. The Guide should also be useful for Royal Army Medical Corps officers, especially those of the junior ranks who may have to give courses of instruction to their corps orderlies-The practical value of the book has been greatly increased in the present edition by the inclusion of blank leaves between the various chapters and sections for notes, and also by the inclusion of references to the Military Medical Regulations, from which answers to questions have been taken. It is to be regretted that the author has not seen fit to include an index.

The Shadows of the Valley. By the Rev. A. G. MORTIMER, D.D. London: Skeffington and Son. 1909. Pp. 275 Price 5s. net.—The sub-title of this book, "A Practical and Devotional Guide in Sickness and Death," sufficiently explains the purpose of its author, who is the Rector of St. Mark's, Philadelphia, in having written it. The work is divided into three parts, of which Part I. may be called a commentary upon the Office for the Visitation of the Sick as it appears in the Prayer Book of the American Church: the Office is practically the same as that appointed by the English Church. Parts II. and III. deal with sickness and death respectively, and treat of these two all-important matters from the point of view of the sufferer and his spiritual adviser. There comes a time to all medical men when they can do no more for their patients, and at such times the physician of the body gives place to the physician of the soul, who, even if the dying man is unconscious, can comfort those to whom he is dear. Dr. Mortimer's book should be of much use to the clergy, to the sick themselves, and, in fine we may add, to all those who believe that the end of this life is not the end of all things. There is an excellent chapter upon the care of the dead.

Norwegian Self-taught, with Phonetic Pronunciation (Marlborough's Self-taught Series). By C. A. Thimm. Fourth edition, revised and enlarged by P. Th. Hanssen. London: E. Marlborough and Co. 1909. Pp. 128. Price, wrapper, 2s.; cloth, 2s. 6d.—In noticing previous volumes of this series we have mentioned that they are likely to prove useful to all who wish to obtain a speaking or reading acquaintance with a language without devoting too much attention to the grammar. This volume is very similar to the others which we have reviewed. It contains just those words which are likely to prove useful to a traveller in Norway. The grammar supplied is very elementary and occupies only some nine pages. The phrases are many and convenient, and wherever a Norwegian word is used its pronunciation is given under a simple system so that the reader should

have no difficulty in pronouncing the word so as to be understood by the inhabitants of Norway, even though the finer nuances are necessarily missed.

JOURNALS AND MAGAZINES.

Archives of Pediatrics. Edited by LINNEUS EDFORD LA FÉTRA, M.D., and ROYAL STORRS HAYNES, M.D. Vol. XXVI., No. 9. September, 1909.—This American journal is well known all the world over to those who are interested in the diseases of children. The September number of this year is an excellent one and in it Dr. P. J. Eaton contributes a very practical paper on "A Few of the Things a Pediatrician Should Teach." The great fault of specialists in diseases of children is that few of them have had opportunity for studying the infant and the child in health. The management of the nursery and the training of the infant are of far greater importance than subtle points in diagnosis and pathology. Dr. Eaton insists strongly that physicians should be able to instruct mothers and nurses on such important matters as the regulation of sleep, exercise, digestion, and defectation. He insists that dentition is only a physiological process when normal, and that lancing of the inflamed gums so as to free the erupting tooth at once relieves symptoms and restores the alkalinity of the saliva. Dr. G. R. Satterlee quotes a case in which the status lymphaticus was diagnosed during life, and apparently confirmed by Roentgen ray photography; the case, which was shown at the Section of Pediatrics (New York Academy of Medicine) gave rise to an interesting discussion. Altogether this number of the Archives is a good one; it reflects great credit on the joint editors and will well repay perusal. An article on Bacterial Vaccines by Dr. B. Raymond Hoobler, and a report on two cases of empyema by Dr. Oscar M. Schloss especially deserve attention.

Edinburgh Medical Journal.—Two introductory addresses appear in the November issue of this magazine—one by Professor Arthur Robinson, entitled "A Glance at Anatomy from 1705 to 1909," and the other by Mr. H. Alexis Thomson on the subject of surgery. Both deal retrospectively with the Edinburgh school, and together they indicate the connexion between anatomy and surgery and between surgery and physiology. Dr. Lachlan Grant writes on the Medical Man as a Reformer and enforces the need for a Minister of Public Health, supported by an adequate staff of experts, to deal with the whole field of public health administration. This paper has been already noticed in The Lancet. Mr. James M. Graham advocates the treatment of mammary abscess by suction and quotes a series of cases in which strikingly good results were obtained.

The Medical Chronicle. - The October number of this journal contains an account by Dr. Judson S. Bury of an interesting case of sarcoma affecting the crus, corpora quadrigemina, and optic thalamus, in which there was no hemianopsia, and none of the usual symptoms of intracranial tumour, in the form of vomiting, headache, or optic neuritis, but paralysis of the motor nerves of the right eye and loss of stereognostic sense in the left hand. Dr. W. J. S. Bythell deals with the skiagraphy of renal and ureteral calculi, emphasising the importance of proper preparation of the patient, and illustrating his article with a series of typical X ray photographs. Dr. Eugene S. Yonge writes on Paroxysmal Rhinorrhœa and discusses the indications for surgical interference in these cases and the varieties of operation which may be undertaken. --- In the November number is published an abstract of a dissertation by Dr. George Duncan Dawson on the Pharmacology of Phytolacca abyssinica, which would seem to contain an active principle allied to digitalin in its action, increasing the force of the

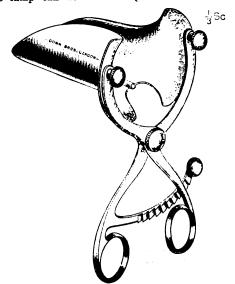

heart's beat, constricting the blood-vessels, and raising the arterial pressure. It is not at present in clinical use, but the author believes that it may prove of value. A somewhat brief abstract of a similar dissertation by Dr. C. E. Lea deals with Cardiac Arrhythmia, with especial reference to so-called nodal rhythm, in which the contraction of the ventricle coincides with or precedes that of the auricle. Dr. Lea finds that it occurs chiefly in mitral disease and in arterio-sclerosis.

The Dublin Journal of Medical Science.—An introductory lecture delivered by Dr. A. Campbell Geddes, and published in the November issue of this magazine, is devoted to a study of the Aims of Anatomy. He endeavours to correlate certain physical and physiological peculiarities, suggesting, for example, the existence of an abnormal human type possessing short bodies, long legs, and a lack of reproductive power, and also a connexion between full veins on the thoracic wall, and increased intrathoracic venous pressure due to smallness of the pulmonary veins. This latter peculiarity may induce defect in the lymph-flow and favour the lodgment of the tubercle bacillus. Mr. William Taylor records two cases of hæmatemesis successfully treated by operation. He advocates such treatment in all cases of bleeding which is apparently due to a chronic, as opposed to the ordinary acute, ulcer of the stomach.

Hew Inbentions.

BLADDER SPECULUM FOR OPERATIVE WORK.

THE illustration represents a dilating bladder speculum made for me by Messrs. Down Bros., St. Thomas's-street, London, S.E. The handles of the speculum are provided with a toothed rack, and may be used closed when examining the prostatic region or the pouch left after prostatectomy, or expanded, as shown in the figure, as when excising villous growths. On the hinged side of the speculum an opening is left through which an electric lamp can be inserted (unless a head lamp be

preferred). The reverse side of the speculum gives sufficient dilatation to allow freedom for operative work, such as the excision of the base of a villous growth, the bevelling of the blades enabling the base of the growth to be brought near the surface and the mucous membrane of the bladder sutured. The speculum was designed to meet a distinct want, and the various bevels and dimensions have been carefully worked out; it has proved in practice to be a very useful instrument.

Bristol. THOMAS CARWARDINE, M.S.Lond., F.R.C.S.Eng.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

FRIDAY, Nov. 26TH.

The Council resumed its sittings to-day, Sir DONALD MACALISTER, the President, being again in the chair.

The Medical Curriculum.

The debate on Dr. J. Y. MACKAY'S motion approving of the recommendations of the Education Committee with regard to the curriculum in medicine was continued.

Mr. Hodsdon said it was evident from what had fallen from previous speakers and also from the various proposals laid before the Council that the present state of affairs was not quite satisfactory. As had been pointed out, they must keep in mind that the General Medical Council had to legislate for duly qualified medical practitioners and not for specialists. When the curriculum was extended to five years the intention was that the fifth year should be devoted to clinical work. But when they came to look at the figures they found that taken all over, there was only an average of 13.8 per cent. of students who qualified in five years. If they looked to the cause of this and closely studied the figures put forward by the chairman of the Education Committee, they found that the earlier subjects had been encroaching on the final group to a great extent, and the remedy was either to lengthen the curriculum, which was not expedient at present, or to adopt some such proposal as was put forward by the Education Committee. That proposal would constitute a new departure and it therefore behoved the Council to proceed cautiously. But he was convinced that if the proposals of the committee were adopted-and he hoped they would be—the effects would be beneficial. Licensing bodies would see that the earlier subjects were taught with a sense of due proportion and the importance of clinical work would be made permanent. Further, the student would have it brought under his notice that unless he devoted a certain time to clinical work he would be retarded, and consequently he would quickly adapt himself to the new circumstances. He supported the report cordially and hoped that it would be adopted.

Mr. THOMSON said that hardly any one of the speakers had gone into the details of the committee's recommendations. Dr. Norman Moore had spoken in generalities. Christopher Nixon had carefully avoided any question of detail and had expressed the hope that whatever happened the medical student might not be hardly dealt with. The President had for their benefit paraphrased the recommendations of the committee. It seemed to him (Mr. Thomson) odd that the recommendations of such a committee should require such a paraphrase or any explanation. From the remarks the President made it appeared that what was meant was that for two and a half years the student would give his undivided attention to the final studies, and that he would not be allowed to go up for examination in them until two years had elapsed after passing the examination in anatomy and physiology. Dr. Mackay had expressed dissent from this reading of the recommendations by the l'resident. He (Mr. Thomson) had had the same difficulty in understanding the recommendations as many members of the Council had. There was no mention of a "block' Dr. Mackay's address when he introduced the matter. It was in the details of the scheme that its application might be harmful. Dr. Mackay had advanced as evidence in proof of the sufficiency of five years for the curriculum the fact that a certain percentage of men in the Victoria University obtained their qualification in five years. He had also mentioned the fact that in Glasgow there was a large proportion of men who took their degree in the same time. He was grateful to Dr. Mackay for having drawn attention to that fact. In the Education Committee's report of 1908 they would see under the heading "University of Glasgow" that 20 men out of a total of 56 passed in a 57 months' course. Let them look at the total length of time occupied in the first and second examinations and they would find it was 34.2 months. The time given to the examinations in medicine, surgery, and midwifery was only 22.8. It was not

his business to explain these figures, but he would draw from them a certain inference—that was, that the men who were delayed by the high standard of examination were able by their own energies to recover and acquire the sufficiency of knowledge which Dr. Mackay himself emphasised by a reference to the inspector's report. Now, Dr. Mackay could not have it both ways. If he set this forward as a proof that the work could be done in five years, he (Mr. Thomson) must point out to him that it was also the most convincing proof of the possible hardship which the insistence upon these 27 months subsequent to the passing of the anatomy and physiology examination would result in. If they insisted on these 27 months it would mean that the men who by their own industry and energy had endeavoured to do their best would be penalised. If these 27 months were insisted onand they could only be insisted on by a process of "blocks" it would be impossible for any man, certainly in the Scottish Universities, to get his qualification within the five years.

Dr. Knox confessed to a slight feeling of disappointment concerning the report of the committee. He had looked for a little more progress in the proposals and a little more bold-When the Council last interfered with the curriculum they lengthened it, and they proposed that the last year should be entirely devoted to clinical work. Those proposals were loyally received and acted upon in Scotland, and even up to the present they remained the ideal which both teachers and students in Scotland were working up to. The value of these proposals had been rather neutralised by the raising of the preliminary science subjects to such an important position that practically all students devoted their first year entirely to them. The increasing severity of those scientific subjects had also affected the progress of the student. A great number of extra subjects had been introduced into the final stage of the student's curriculum, subjects like insanity, bacteriology, diseases of the eye, ear and throat, to all of which the student felt he must devote a considerable amount of time. These things had altered the aspect of affairs since the Council last amended the curriculum. For these reasons he would have expected that when now they had tackled the question of the curriculum they would have shown a little more boldness than they had done and would have endeavoured—he did not say by what means—to lighten the student's work, to make it easier, and to promote so far as possible a greater attention to the final subjects. The effect of the committee's recommendations seemed to be that all students with the view of being certain in their anatomy and physiology would devote still more time to these subjects. That was not in itself a bad thing. But when they considered there was such a short period of 21 or 27 months for the final subjects he did not see how they could possibly be otherwise than hindered and their examinations in the final subjects retarded. He thought the curriculum would be extended considerably owing to this implied or avowed "block" in the middle of it. He did not like a "block" at all, and especially disliked it between anatomy and physiology on the one hand and medicine and surgery on the other. As a teacher of surgery he rejoiced when he got hold of men who knew their anatomy well. That was the way men made greatest progress in surgery and distinguished themselves in examinations. Surgery and anatomy were one and indivisible, and even in the case of physiology it was impossible to separate it from the practical. If there was to be any "block" he would leave it to the students to find where it was possible to expand their energies and where it was possible to concentrate. So far as he could see from the discussion that had taken place they were face to face with an extension of the curriculum. How it should be done and in what way he did not know, but he would be inclined to suggest, seeing there was a difference of opinion on the subject, that the Education Committee should take back their report to see whether they could not make a more advanced proposal. The report was such a slight advance that no great harm would be done if a pause were made to allow the committee to bring up further proposals modifying and probably extending the curriculum.

Dr. TAYLOR expressed dissent from the views enunciated by the last speaker. He thought there should be a period of undivided clinical study. He had been struck with the fact Mr. Thomson mentioned, that so few speakers had tackled the details of the recommendations, and he had also been

impressed with the fact that nobody had moved an amendment. Therefore the conclusion must be drawn that they were all agreed upon it. He was convinced that a student could not adequately study medicine unless he knew his anatomy and physiology thoroughly, and to invite students to learn medicine in their second year before they had got a thorough grasp of anatomy and physiology was a mistake. He was in favour of the principle underlying the committee's recommendations. The question of whether two years or two and a half years should be adopted was not before them in that particular form, and it might be safer to adopt a minimum of two years to begin with. In the case of two and a half years he did not see any exceptional difficulty so far as the five years' curriculum was concerned.

Dr. LATIMER said that although the curriculum had been extended to five years it was not a five years' curriculum. The curriculum from various causes reached an average of nearly seven years. He thought, however, that they should aim at something which would enable students to learn their profession and practise it confidently within a period of five years. If there was to be a "block," it should be at the commencement of the curriculum and not during its progress. The earlier subjects could be taught in schools to enable the students to pass in them in the preliminary examinations.

Dr. D. C. McVail said that nobody had proposed to lessen the number of subjects required for the medical diplomas. Nobody had proposed to leave out biology, physics, chemistry, or anatomy. All these subjects had been taken for granted in the debate, and none of the subjects introduced 15 years ago were to be got rid of. Were any of these subjects examined in with undue severity? Had the Universities and the Colleges required too much knowledge in the subjects of biology, chemistry, physics, or anatomy! Not to his know-He had seen no complaints of that. Nothing had come before the Examination Committee to show that the examinations in these subjects had been unduly severe. one proposed that there should be less practical teaching. Where was the difficulty then? The difficulty was in the five years. Five years had become too short a time for the average student. That was all. He did not think it showed failure in their system of teaching or examining that so few took their curriculum in five years. There were, no doubt, exceptional men who in five years could master all the subjects, but they must always be in the minority. If any student who desired to take a reasonably good position in his profession were to ask him what time he should devote to his curriculum he would reply, "No less than six years, and if possible seven." The average man could not put all these subjects into five years, and the very good men did not want to do it. They would never get a five years' curriculum with the present subjects. That being so, it seemed to him it was no business of theirs to try to impress on the examining bodies or the students that they should qualify in five years. The General Medical Council had to see that the persons to be entered on the Register had been adequately taught and examined. It lay with the Council to say what the subjects should be in the qualifying examination, but for the Council to try by any artificial manœuvre to make the bulk of the students cram up all these subjects in five years was not their duty. He was entirely against introducing any "block." The student would introduce his own "block." The schools were doing admirable work. The difference between the questions set at examinations 30 years ago and now was almost inconceiv-The progress that had been made by the profession able. since the General Medical Council was called into being had been enormous, and that had been largely brought about by the Council itself. There was not the slightest need for the Council now to take up the whole thing by the roots. He knew how enormously the schools in Scotland had improved in teaching and how much better the students were educated in them than when he knew them first. In England what a wonderful development there had been in regard to the two old Universities, and what a wonderful development there had been particularly in the schools in London! The examinations of the London Conjoint Board and the London University were entirely different from the examinations 30 or 40 years ago. Why should they begin in the way suggested? The schools of London, and others, were perfectly able to give advice to their students without the Council devising any artificial "blocks." Where were the "blocks" to be? Different places had been suggested. If he

were in favour of a "block"—which he was not—he would put it before the men went up to their clinical subjects. talk about a "block" after the science subjects with the assumption that they might be taught in public schools seemed to be quite futile. There were some public schools where no doubt they could be taught, but they could only be properly taught to boys who had got quit of their English, Latin, and mathematics. He was satisfied with the present state of affairs. The last cycle of inspections and visitations showed a level that never had been reached before, and when the time came for another circuit he had not the least doubt that still greater improvement would be shown. While it had been very serviceable that the Education Committee should have collected all these facts and figures he did not think that any case had been made out for the Council to interfere just now. Therefore he could not support the committee's resolution in so far as it involved the putting in anywhere of a "block."

Dr. McManus said he realised that anatomy and physiology were the foundation of all things, but he suggested that the sooner they got the young men into the wards and the longer they kept them there the better it would be for the public. Although he sat under some of the greatest professors in Dublin, he did not remember a word of their lectures, but what he learned from these same professors in the wards he had never forgotten. If they had fewer lectures and more practical work the better it would be for the rank and file of the profession.

Dr. ADYE-CURRAN said that year after year he had listened to suggested proposals for adding to the curriculum, and heaven only knew where it would end. In a year or two the curriculum would be extended probably to ten years, and it would cost £1000 to qualify. If this perpetual addition to the final was to go on something should be taken away from the preliminary. In the first year or two the student learned nothing about medicine proper. All he learned were extraneous subjects that could be referred to the schools. What would be the result of these proposals before them? Their result would be that there would be no medical students, because parents could not afford to keep their sons six or seven years while they completed their studies. He hoped the five years' curriculum would be fixed definitely once and for all, and that it would not be left in the unsettled state it was in at present.

Dr. CATON said the committee's recommendations offered a via media which would allow the student to disencumber his mind of the earlier subjects and so leave him free to give his sole attention to the later subjects.

Dr. MANN said they ought to insist upon the student's knowledge of chemistry, physics, and biology, so as to have well-educated men in the profession. He agreed with Dr. McVail about the difficulty of getting these subjects taught in schools. He knew the kind of thing that was taught in schools: the students got a smattering of all the "ologies" and got nothing of anything that was worth preserving. To put these subjects into the elementary part of the student's career before he began the study of his profession would result in the profession itself suffering.

Dr. MACKAY, in reply, said the Education Committee had been assailed on two sides. On the one hand, they were attacked for having gone too far, for having put forward proposals which would seriously retard the student, and for not considering the student. On the other, they were assailed because their action was not bold enough. The committee had adopted a via media. The reports of the committee on this subject were spread over three or four years, and because all these reports were not before the Council he admitted it was a little difficult to grasp all the Those reports contained many findings on many subjects, but the committee had not put all the findings before the Council; they had simply taken out what seemed to be the most pressing necessity of the time and addressed themselves to that. They had put forward a conclusion which referred directly to the length of the curriculum. The other matters in the reports were not ripe for solution and might be taken up hereafter. He had decided to put before the Council an amended motion in more formal and precise terms in place of the motion on the paper. This was as follows:

That in the opinion of the Council the regulations of the licensing bodies should be so framed as to ensure that the study of the final group of subjects in the medical curriculum, including pathology, medical jurisprudence, public health, therapeutics, midwifery, surgery,

and medicine, shall be pursued (a) throughout a period not less than two and a half academic years (27 months) following upon the completion of the examination in anatomy and physiology; or (b) throughout a period not less than three academic years (33 months), two of which (21 months) shall be subsequent to the completion of the abovementioned examination.

The committee believed there was no danger in overlapping if it was not carried too far, and they desired each body to select either of the alternatives, which were absolutely equivalent in time value. There was no proposal in the scheme to limit the period of final study to the last part of the curriculum. The final study might begin at any time according to the wishes of the body. It had been pointed out to him that there were cases in which it would be exceedingly hard to enforce those rules absolutely, and he proposed to add to the motion he had just read the following:—

Any case of exemption from this rule should be reported to the Council by the licensing body granting the exemption.

That admitted the principle of exemption and freed the bodies to suggest any form of exemption they thought The committee did not think the time had come necessarv. to establish a six years' course, but the laying down of the reforms in the motion would have the effect of forcing many of the bodies to reconsider the arrangements of the earlier part of their curriculum, and indirectly it would prevent the necessity for a six years' course in the immediate future. When the time came to make another rearrangement it would probably be the final portion of the course that would require extension. That, however, was a matter for future consideraton. The committee at the present moment did not think the time was ripe for relegating to the schools the medical requirements in chemistry, physics, and biology. An interesting experiment was being carried on at present in connexion with this matter. The English bodies had recognised a certain number of selected schools, and students were coming up from these schools, having passed through the school curriculum in these subjects. The committee had not yet had time to judge of the results. The greater number of the schools in the country were not in a position to take up the requirements in these subjects and deal justly with them, particularly in the department of biology. Although he was a young member of the Council he had already learned that the business of the Council was to lead and not to drive, and that they would likely do damage if they pressed bodies to adopt any policy or course against their will. That was the reason why the committee had put forward no drastic proposal. They sought only to establish a principle which they felt would be accepted. It could be extended in due course if it was found necessary or expedient.

At the suggestion of the PRESIDENT, Dr. MACKAY did not put the amended resolution in the form in which he read it to the Council. Instead he proposed the motion in the following terms:—

That the regulations should be so framed as to ensure that the study of the final group of subjects should extend over not less than two and a half academic years after passing of the examination in anatomy and physiology.

S'r HENRY MORRIS said he thought they should do what was practicable and likely to be accepted by the various bodies. He thought, considering what had been practicable up to the present, the time had hardly come when they could ask all the examining bodies to insist upon two and a half years. He therefore moved as an amendment that the following should be substituted for Dr. Mackay's motion:—

That the regulations should be so framed as to ensure that the study of the final group of subjects should extend over not less than two years after the passing of the examination in anatomy and physiology.

Dr. NORMAN MOORE seconded the amendment.

On a vote Sir Henry Morris's amendment was carried by a substantial majority. It was then put as a substantive motion and agreed to, with two dissentients.

On the motion of Dr. MACKAY, it was decided that the two years mentioned in the resolution should be defined as 24 months.

The PRESIDENT said that the addition suggested by Dr. Mackay regarding exemptions was not necessary as exemptions were already provided for.

Sir HENRY MORRIS moved :-

That it be referred to the Education Committee to consider further the place in the student's career which the preliminary sciences should occupy; and that the committee be requested to frame and submit to the Council a pattern scheme of medical education whereby the required minimum of the several subjects to be included in the curriculum can be adequately studied and the requisite examinations

thereon passed by the average student within the period prescribed by the curriculum.

In the near future, he said, the question of the re-arrangement of the earlier part of the curriculum must arise. He had had investigations made with regard to the matter, and the figures showed that those boys who had been trained in the early subjects in the general schools of the country passed in greater proportion than those who had been trained in the various medical schools. He proposed the motion with the view of trying to standardise the minimum required for the curriculum.

Sir C. NINON seconded. The main consideration of the Education Committee, he supposed, would be to see whether they could not put the subjects of the preliminary education outside the medical curriculum. If the motion meant anything it meant a reconstruction of the medical curriculum.

The PRESIDENT: No, I don't think that.

Sir C. NINON: Then what does it mean?

The PRESIDENT: The Education Committee will tell you when they report.

Sir C. NIXON said he supported the motion believing it desirable that a radical change should be made in the medical curriculum.

Dr. MACKAY said the Education Committee would gladly do its best to look into this question, although he was not hopeful that a curriculum could be drawn up which could be done by the average man in less than five years.

Dr. McVAIL said that knowing, as he did, the system of medical education in Scottish Universities he felt perfectly certain they would never dream of accepting school botany, school zoology, school chemistry, or school physics as part of the curriculum for the medical degree.

The PRESIDENT: I do not think that is raised here.

Dr. McVail: I think it is. The Council was going to ask the committee to lay down a pattern scheme. That meant that the Council was dissatisfied with the present scheme, and that it admitted the present scheme was not a pattern scheme. That was what certain of the Scottish Universities would never look at, and if the Universities of Scotland would not take it on it was extremely unlikely the English Universities would do so. It would create a big division between degree-granting authorities and authorities that did not grant degrees but granted diplomas. It was a dangerous resolution in his opinion, and he objected to it being sprung on the Council without notice.

The motion was carried by 17 votes to 5. Ten members did not vote and two were absent.

Dr. SAUNDBY moved that -

The question of allowing candidates to enter for each of the subjects separately of the final examination in medicine, surgery, and midwifery be remitted to the Examination Committee for consideration and report.

He mentioned that a great deal of interest was taken in this matter. This was particularly so at Edinburgh. He would content himself in moving his motion in a few words.

The motion was agreed to.

Penal Procedure.

The Council received in camera a report from the Executive Committee with regard to penal procedure.

Penal Cases.

The Council resumed the hearing of penal cases.

The case was considered of William Shaw, registered as of Larne, co. Antrim, Lic. R. Coll. Phys. Edin. 1886, Lic. R. Coll. Surg. Edin. 1886, who was summoned to appear before the Council on the following charge as formulated by the Council's solicitor:—

That you were convicted on March 24th, 1903, and again on March 23rd, 1909, at the Larne Town Court of being found drunk in a public street, and on August 24th, 1909, at the Larne petty sessions of the following misdemeanour—namely, of being found on licensed premises in contravention of the provisions of the Licensing Acts.

Mr. Shaw did not attend but he sent a letter of explanation.

The PRESIDENT, in delivering the decision of the Council, said: I have to announce that William Shaw, having been proved to have been convicted of divers mislemeanours alleged against him in the notice of inquiry, the Registrar has been directed to erase his name from the Medical

The Council then considered the case of Harry Robert Ruthority or combination of Authorities must conduct the Emms, registered as of 132, Winson Green-road, Birmingham, Mem. R. Coll. Surg. Eng. 1896, Lic. R. Coll. Phys. be examined in all three subjects by one Medical Authority

Lond. 1896, who was summoned to appear before the Council on the following charge as formulated by the Council's solicitor:

That you were on June 16th, 1909, convicted at the Cambridge Borough police-court of having on May 28th, 1909, feloniously stolen a bicycle belonging to one Debendra Mohan Bose, and on June 7th, 1909, of having feloniously stolen a New Chesterton bicycle belonging to one Alfred Conway, and a Standard Triumph bicycle belonging to one Thomas James Mudd.

Mr. Emms did not attend.

The PRESIDENT, in intimating the finding of the Council, said: I have to announce that Harry Robert Emms having been proved to have been convicted of the felony alleged against him in the notice of inquiry, the Registrar has been directed to erase his name from the Medical Register.

The last case was that of James Alexander Pettigrew registered as of 11, Lowther-street, Whitehaven, Cumberland, "in practice before July 22nd, 1878."

The Dental Committee to whom the case was referred found that the following facts were established by the evidence:—

That on Jan. 4th, 1909, the said James Alexander Pettigrew was convicted at the Lancaster Quarter Sessions of unlawfully and wilfully neglecting certain children under the age of 16 years in a manner likely to cause them unnecessary suffering and injury to their health, and was sentenced to six months' imprisonment with hard labour. The evidence before the Committee consisted of the certified copy of the said conviction.

The PRESIDENT, in delivering the decision of the Councilsaid: I have to announce that James Alexander Pettigrew having been proved to have been convicted of the misdemeanour alleged against him in the notice of inquiry, the Council has directed the Registrar to erase from the Dentists Register the name of James Alexander Pettigrew.

The Apothecaries' Hall, Dublin.

The report by the Examination Committee on the report of the final examination of the Apothecaries' Hall, Dublin, held in January, by the assistant examiners in surgery (Sir Lambert H. Ormsby and Professor Conway Dwyer), was received.

Dr. McVail moved that the report on the final examination of the Apothecaries' Hall held in April should likewise be received and entered in the minutes.

The Examination Committee mentioned in the report that the assistant examiners were satisfied with the manner in which the examination was conducted, and they (the assistant examiners) considered the standard of proficiency in medicine, surgery, midwifery, and ophthalmology required from the different candidates was searching and sufficient in every detail. The Examination Committee drew attention to a case in which a candidate was exempted in a subject of medicine in the final examination on the ground that he had passed in it elsewhere. Some correspondence had passed between the registrar and the authorities of the Apothecaries' Hall, Dublin, on the subject. A part of that correspondence was included in the report. Mr. H. E. Allen, the registrar of the General Medical Council, in the course of a letter pointed out it did not appear to be permissible to exempt the candidate in a subject in the Final Examination. Mr. Henry W. Mason, the secretary and registrar of the Apothecaries' Hall, in replying stated that "when the candidate made application for admission to our Final Examination he requested exemption in Midwifery, having already passed in this subject elsewhere. Before acceding to his request, being ourselves doubtful on the point, we wrote you on 2nd of October, 1908, for definite information on the point of exemptions. Your reply of October the 3rd was very full and explicit, stating that there was no rule on the subject, and consequently the candidate was admitted to Examination and allowed the subject. We therefore hold ourselves blameless in the matter, and would not have acted as we did save and except for your reply." Examination Committee in their report quote from the minutes a similar case in 1903, where it is stated that the recognition of a final subject passed before a different licensing body is quite irregular, in view of the opinion expressed by the Council's legal adviser, that "the Examination must be one Examination, in the sense that one Medical Authority or combination of Authorities must conduct the whole Examination of the Candidate; that is, that he must or combination of Authorities." The report concludes as follows:

The Examination Committee regrets that again a procedure should have been adopted by the Apothecaries Hall which in the opinion of legal counsel is illegal. The Examination Committee is of opinion that the Council should draw the attention of the Apothecaries' Hall to the opinion given by the Council's legal adviser regarding what constitutes a Qualifying Examination. The Committee is further of opinion that the Council should call the attention of all the Licensing Rodles to this opinion. The Committee regards the Reports of the Assistant Examiners to the Apothecaries' Hall as not sufficiently full and definite, and it suggests that in future the Assistant Examiners be supplied with a form of schedule to be filled in by them in the case of each candidate.

Dr. ADYE-CURRAN took objection to the reception of the report on the ground that the full replies of the authorities of the Apothecaries' Hall were not included in the correspondence. In conclusion, he moved as an amendment:

That the report of the Final Examination of the Apothecaries' Hall of Ireland be again postponed till the May session, in order that the remarks of the body concerned may be added.

Dr. McManus seconded.

The debate was adjourned and the Council rose.

SATURDAY, Nov. 27th.

The Council resumed its sittings to-day. Sir DONALD MACALISTER was again in the chair.

The Apotheoaries' Hall, Dublin.

The debate was resumed on Dr. Adye-Curran's amendment to Dr. McVail's motion with regard to the report on the Final Examination of the Apothecaries' Hall, Dublin.

Dr. McVail reviewed at some length the matters dealt with in the report. The Council, he said, was responsible for having things done according to law, and he did not think that the report should be postponed at all.

Dr. ADYE-CURRAN maintained that everything that had been done by the Apothecaris' Hall, Dublin, had been done There had been a mistake. For years past there had been every endeavour on the part of the Hall to fall in with the wishes and decrees of the Council in every possible way.

Sir HENRY MORRIS asked whether there was any objection to the report being postponed for six months. It might be desirable if the matter were important to have the remarks of the body concerned.

Dr. McVail read the correspondence which was not printed in the report.

Dr. ADYE-CURRAN withdrew his amendment on the understanding that this correspondence would be included in the minutes.

The motion to receive the report was agreed to.

Dr. McVail then moved that the Council should express approval of the following paragraph in the report:-

The Education Committee regrets that again a procedure should have been adopted by the Apothecaries' Hall which in the opinion of legal counsel is illegal.

Dr. NORMAN WALKER seconded.

Dr. Adye-Curran considered that the motion was rather severely worded. The Hall was not to blame. The Council had made a mistake.

The motion was carried by by 19 votes to 4. members did not vote and seven were absent.

The three other paragraphs in the conclusion of the report

Apothecaries' Hall, Dublin: Preliminary Examination.

Dr. MACKAY, chairman of the Education Committee, submitted the following report:

The Committee, having considered an application from the Apothecaries' Hall, Dublin, regarding the recognition of its preliminary examination, passed the following resolution: "That the application be refused, and that for the reasons the applicants be referred to the decision of the Council as reported in the minutes for 1894 and 1908."

In moving the adoption of the report, Dr. MACKAY said the committee believed that it was not right that a body which was concerned purely with medical education should conduct a preliminary examination in general education. Such an examination should be conducted only by a body which was in close touch with the general education of the country and never by a body whose sole interest in such an examination was the admission of students to the medical curriculum. The committee wished in no way to discourage the legitimate efforts the Apothecaries' Hall were making in Ireland. If there were difficulties in their way now was the time that a serious effort should be made to remedy these

difficulties in a proper manner. They had now in Ireland new universities, and it would be a very proper thing if all the bodies in Ireland concerned were to get from the new universities a preliminary examination in general education conducted by an impartial body representative of them all. He trusted the action of the Council would have the result of bringing about the establishment of a general educational body in Ireland which would do for that part of the kingdom what similar bodies were doing in other parts of the country.

Dr. ADYE-CURRAN maintained that the Apothecaries' Hall was obliged under Act of Parliament to hold these examinations. No man could be admitted as a licentiate of the Apothecaries' Hall unless the directors satisfied themselves of his proficiency in general education. In that way the Apothecaries' Hall differed from other bodies. They had

a perfect right to hold these examinations.

The PRESIDENT pointed out that such recognition by the General Medical Council would mean the endorsement of the examinations for every body besides the Apothecaries' Hall whether they liked it or not. What Dr. Adye-Curran had said was irrelevant to the main question. There was nothing to prevent the Apothecaries' Hall starting any examination they liked so long as it was for their own consumption.

On a vote the report was adopted by 27 votes to 1.

Dental Registration.

Mr. Tomes moved the reception and adoption of a report from the Dental Education and Examination Committee in regard to an application from Mr. H. M. McNeill for dental registration. The report stated that on Jan. 20th, 1909, an application for registration in the colonial list of the Dentists Register was received from Mr. H. M. McNeill on the ground that he possessed the L.D.S. diploma of New Zealand and the D.D.S. of the University of Toronto. The application was refused. Mr. McNeill appealed to the Privy Council, and on June 20th the Privy Council was informed of the grounds upon which the refusal was based. The report entered at length into an explanation why the committee The report considered that the possession of the diplomas tendered was not sufficient in its view for the registration which was Mr. Tomes mentioned that the Council had applied for. always held itself entitled to inquire into the circumstances of colonial registration.

Dr. KNOX seconded.

The motion was agreed to.

The Pharmacopaia Committee.

On the motion of Sir John Moore the report of the Pharmacopæia Committee was received. The report was as follows:

From May 23rd to Nov. 22nd, 1909, the number of copies of the British Pharmacopæia (1898) sold by the publishers was 578. The total number of copies sold in the year beginning Nov. 23rd, 1908, was 1060. The annual demand for the existing Pharmacopæia thus appears to remain steady. Up to the present time 41,366 copies of the Pharmacopæia and 4458 copies of the Indian and Colonial Addendum have been sold. The stock now in hand consists of 1664 copies of the Pharmacopæia, together with 1876 copies of the Addendum.

The committee met on Oct. 22nd and 23rd and considered in detail the suggestions made by the licensing bodies and other medical authorities at home and abroad for the improvement of the Pharmacopæia, with a view to its forthcoming revision. Provisional decisions were arrived at concerning the omission or inclusion of particular drugs and preparations. On a number of points it appeared that further inquiries were necessary before definite conclusions could be reached. Meanwhile the committee has resolved that the matter now included in the Indian and Colonial Addendum, or such part of it as after due revision is retained, shall be incorporated with the text of the next Pharmacopæia. In this way practitioners and pharmacists throughout the empire will be provided with a comprehensive British Pharmacopæia in one volume, in which due account is taken of local conditions and requirements.

Students' Registration.

On the motion of Sir Hugh Beevor, the report of the Students' Registration Committee was received.

The Anæsthetics Committee.

The PRESIDENT moved the reception of the report of the Anæsthetics Committee, which was appointed on May 29th.

To consider the proposals for legislation on the subject of anæsthetics which have been or may hereafter be put forward, and to report to the Council on the position of the subject at the November session.

The committee had before them the Anæsthetics Bill, 1909, the text of which was printed in the report.

After careful consideration of this Bill and of other

communications on the subject which had been placed before them, the committee came to the following conclusions:

1. That the statutory powers with regard to medical education exercised by the Council, and in case of need exercisable by the Privy Council, are sufficient to secure that candidates for medical or dental qualifications shall have received adequate practical instruction in the administration of aneathetics, and that the Council has already taken steps, and is prepared to take further steps, to secure the end in view.

2. That it is inexpedient to provide by Act of Parliament that evidence of such instruction should be raised to the status of an "additional qualification," without which no person shall be entitled to registration.

2. That it is inexpedient to provide by Act of Parliament that evidence of such instruction should be raised to the status of an "additional qualification," without which no person shall be entitled to registration.

3. That in the exercise of its statutory powers with regard to medical education the Council is enabled to take account from time to time of the advances of medical science in regard to the methods of procuring anæsthesis, and to vary its recommendations to the licensing loadies accordingly, in a manner which would not be practicable under the terms of the proposed Bill, should that pass into law.

4. That it is desirable in the public interest that the administration of anæsthetics for the purpose of inducing unconsciousness or insensibility to pain during medical, surgical, obstetrical, and dental operations or procedures should be restricted by law to duly qualified medical practitioners, due provision being made for the practical instruction of students, and for cases of eme. gency.

5. That having regard to existing conditions it is also desirable in the public interest that duly qualified dental practitioners should be authorised to administer certain specified anæsthetics, such as nitrous oxide gas, for the purpose of inducing unconsciousness or insensibility to pain during dental operations or procedures.

6. That the specification of the anæsthetic substances or drugs which may thus be employed by duly qualified dental practitioners during dental operations or procedures should be made in a schedule to the proposed Act of Parliament, power being reserved to the Privy Council on the recommendation of the General Medical Council as the authority charged with the publication of the British Pharmacopeia, to add to or vary the specified list from time to time as occasion arises.

7. That it is expedient in the public interest to provide that the person who administers the anæsthetic for the purpose of inducing unconsclousness during any medical, surgical, or dental operation or procedure, due p

The committee recommended that the foregoing conclusions should be adopted by the Council and transmitted to the Lord President of the Privy Council for his information.

Sir C. BALL seconded.

The motion was agreed to.

The PRESIDENT, in reviewing the conclusions in the report, said that the committee was satisfied that the powers already possessed by the Privy Council were sufficient to allow steps to be taken from time to time to insure that the medical or dental student should be duly instructed in the practical administration of anæsthetics. Therefore an Act of Parliament on this point was unnecessary. The committee believed that the machinery of the General Medical Council was capable of being adapted from time to time. That was better than an Act of Parliament. Conclusion 4 was an important one. With regard to Conclusion 5, the committee had had some trouble in deciding whether the anæsthetics should be specified. The method of meeting the difficulty which the committee had suggested was to allow the Privy Council, on the recommendation of the General Medical Council, to vary the specified list. Further, he thought that the Council had an interest in seeing that the anæsthetist and the operator should be distinct. The danger was greatly minimised when the anæsthetist had his attention wholly directed to his own duties. Clause 4 of the Anæsthetics Bill laid down that "any registered medical practitioner who gives a certificate of death in the case of any person dying while under the influence of an anæsthetic should be liable, on summary conviction, to a penalty not exceeding five pounds." The committee thought it proper that the Council should protest against the creation of a new offence. If it was desired to deal with this matter he thought that it could be done by a system of notification. The committee considered that it was undesirable for the Council to lay down a definition with regard to the "adequate practical instruction in the administration of anæsthetics" which should be required of

candidates for their medical and dental qualifications. duty of the Council would be discharged in impressing on the licensing bodies the necessity for efficient instruction. Further, the committee thought it highly necessary that dental practitioners should have adequate practical instruction in anæsthetics. He concluded by moving in turn the adoption of the conclusions of the report.

On conclusion 5, Dr. KNOX urged that it should be made perfectly clear that the practical instruction of dental students in the use of anæsthetics was desirable. accordingly moved to add to the conclusion, "and that due provision should be made for the practical instruction of

dental students.' This was agreed to.

All the conclusions were adopted.

Sir C. Ball. remarked that the Anæsthetics Committee had performed admirable work.

Application for Registration.

The Council considered an application for registration by Mr. Alfred Alexander Donald McCabe-Dallas, Lic., Lic. Midwif. 1881, R. Coll. Phys. Irel., a medical practitioner entitled to be registered under the Medical Act (1858), but who neglected to effect such registration until after the "appointed day" (June 30th, 1887), under the Medical Act (1886). The application was duly considered by the English Branch Council on Nov. 24th, 1909, when the following resolution was passed :-

That the Branch Council recommends to the General Council that Mr. Alfred Alexander Donald McCabe-Dallas be registered.

The application was granted.

The End of the Session.

This concluded all the business on the agenda. On the motion of Dr. NORMAN MOORE the President was thanked for his services in the chair. The Council then adjourned until May, 1910.

THE JOHN HERBERT WELLS FUND.

THE following is the fifth list of subscriptions to the John Herbert Wells Fund. Further contributions will be gratefully received by the Earl of Dalhousie and Mr. Julian G. Lousada, honorary secretaries and treasurers of the fund, at 16, Old Broad-street, E.C., or by ourselves at this office:--

LANCET. THE

LONDON: SATURDAY, DECEMBER 11, 1909.

The General Medical Council: Proposed Legislation on Anæsthetics.

WE complete this week our report of the proceedings of the November session of the General Medical Council, a very brief session this year, extending only over five days. But, as we have frequently pointed out, the work done by the General Medical Council at its public sessions must not be taken as a gauge, for the labours of the numerous committees, as well as the proceedings of the Branch Councils, have to be added to the sum of its industry. The brevity of the session was largely accounted for by the fact that the discussions on the penal cases were not prolonged, a fact of which the treasurer of the Council must be profoundly glad, for it is in the necessity to make thorough inquiry into all such cases that the risk to the funds of the Council lies. Two matters of outstanding importance were, however, dealt with by the Council in its short session-viz., the arrangement of the subjects of the medical curriculum, and the proposed legislation on the administration of anæsthetics. regard to the first matter we need only record the decision at which the Council arrived, inasmuch as the various preliminary proceedings have been recently summarised in our columns in a series of articles, while the actual debate upon what is known as the "block system" will be found fully reported in our columns this week and last week. The net result of a most interesting debate was summed up in a resolution moved by Sir HENRY MORRIS, that the regulations apportioning the student's time between preliminary and final subjects should be so framed as to ensure that the study of the final group of subjects should extend over not less than two years after the passing of the examination in anatomy and physiology. It will thus be seen that the principle of the "block" was at length decided upon, the only alteration in Sir HENRY MORRIS'S resolution being that the two years were later defined as 24 months.

The attitude of the General Medical Council upon the proposals for legislation with regard to anæsthetics was very clear. The Anæsthetics Committee of the Council, after careful consideration of the proposals for legislation, came to the definite and, if we may say so respectfully, adroit conclusions which will be found fully printed on page 1754 of this issue of THE LANCET. These conclusions were adopted by the Council and have been transmitted to the Privy Council for its information, while the Departmental Committee of the Home Office which is now sitting to consider the Coroners Acts, and which has the whole question of

The meaning of the conclusions which have been adopted by the General Medical Council is that the Council approves of legislation on the administration of anæsthetics in certain directions, although it expresses confidence in its own statutory powers with regard to medical education as being sufficient to secure that candidates for medical or dental qualifications shall receive adequate practical instruction in the administration of anæsthetics. The important things are that the Council has endorsed the following findings of its Anæsthetics Committee :-

(4) That it is desirable in the public interest that the administration of anæsthetics for the purpose of inducing unconsciousness or insensibility to pain during medical, surgical, obstetrical, and dental operations or procedures should be restricted by law to duly qualified medical practitioners, due provision being made for the practical instruction of students, and for cases of emergency.

(7) That it is expedient in the public interest to provide that the person who administers the anæsthetic for the purpose of inducing unconsciousness during any medical, surgical, or dental operation or procedure should not be the person who performs the said operation or procedure, due provision being made for cases of emergency.

Upon the point where the greatest discussion has so far arisen -viz., the position of the dentists with regard to the administration of certain specified anæsthetics—the Council approves the conclusion that having regard to existing conditions it is desirable in the public interest that duly qualified dental practitioners should be authorised to administer certain specified anæsthetics, such as nitrous oxide gas, for the purpose of inducing unconsciousness or insensibility to pain during dental operations or procedures. It was a certainty that the General Medical Council would not support the interference with accepted dental practice that would have been implied in the prohibition of the qualified dentist to use gas. It seems to us that the General Medical Council owes a great debt to its Anæsthetics Committee for a valuable set of conclusions, and is to be congratulated on adopting them in toto. Every single conclusion is not calculated to please everybody, but the General Medical Council meets the position fairly by advocating measures which would maintain the rights of the medical profession as a whole, infringe nowhere those enjoyed by any section of the profession, and furnish distinct degrees of protection to the public.

The Classification of Odours.

LEAST cultivated of all senses perhaps is the sense of smell. There are those who contend that if the subject had received the same attention as have the senses of hearing and sight the study of odours would have reached the scientific plane of optics and acoustics. We classify sounds and colours easily enough, though the methods and results are open to criticism, but we can lay little claim to having set up a scientific division of odours. Is there anything more difficult to describe than a smell? We can say that it is penetrating, persistent, pleasing, or offensive, as the case may be, but these are all adjectives which do not necessarily single out or enable anyone to recognise the particular smell which we wish to describe. new legislation upon anæsthetics before it, will also benefit In our difficulty we dismiss the description of a smell by saying that "it is peculiar." Whilst that is true it conveys nothing, as is pointed out in a suggestive letter in another column from Mr. Morris J. WILLIAMS. The most that we can say is that a certain odour recalls the odour of another substance with which everybody is familiar. We set up, in a word, an odd assortment of smelling substances with which comparisons may be made. We must refer to a well-known smell before we can give any idea of one that is fresh to us. It reminds us, we constantly say when asked to give a description of a novel odour, of roses, of cinnamon, of rotten eggs, of camphor, of earth, of pine, of pigs, of sweat, and so forth, according to the impression which we receive. Such a description can only appeal of course to the person to whom these odours are familiar. But it would be difficult to convey the slightest idea of the smell of (say) the skunk to anyone who has not encountered the emanation of that animal, though once it has been experienced it can never be forgotten, so strong is the impression which it leaves. A sickening sweet repulsive odour is almost all we can say of it, unless we add that it is partly like bad eggs and partly like valeric acid (osmidrosis), when we at once mention a thing which need not be more familiar than the odours of the skunk. It is different in the case of colour, for no one is bound to say, to quote an example, that the sun went down the colour of yelk of eggs or of geranium blossom so long as the distinctive terms yellow and red are understood, while any shade of yellow or red can probably be compared to the colour of some familiar object like the lemon, the brick, or the tomato. The fact is that the classification of smells is rude and unscientific. There are scents more or less attractive and there are stinks repulsive, and between the lines of that broad differentiation we stand nearly still. Further, there is the difficulty that, broad as the differentiation is, there is not always a consensus of opinion to be found as to whether an odour is pleasant or offensive. The odour of turpentine, for example, is acceptable to some persons, but excites disgust in others, and individuals are known to whom such odours as those of carbon disulphide or of sulphuretted hydrogen are a delight. Such an appreciation, however, having regard to the opinions of the majority, is probably based on a perverted instinct, but who in this matter can decide what is the normal impression? It is reasonable to suppose, further, that smells are subjects of favouritism, just as are sounds and colours and their combinations.

That the sense of smell is capable of extreme refinement is evident from the perfection which it reaches in some animals, of which the dog may be quoted as a familiar example. There can be little doubt that certain animals have a remarkable power of differentiation and recognition by their keen sense of smell, but it is questionable whether the same sense, with exceptions possibly, is ever developed so highly in the human being. It is, in fact, not improbable that in the human individual the sense of smell is, as a rule, a dull one, and possibly incapable, therefore, of the scientific differentiation which has taken place in the case of hearing and sight. Nevertheless, certain attempts have been made to place the sense of smell

in the same category as the senses of hearing and seeing by assuming that odours affect the nervous system by special vibrations just as the ether vibrations effect the eye, and air vibrations affect the ear. Perfumers, for example, speak of a gamut of odours, placing the name of the odour in a position corresponding to its effect upon the olfactory sense, in the order of its amplitude of vibration; and many years ago Dr. Shptimus Piesse set out a series of odours in parallel with a musical scale, and showed how it was possible to make a bouquet correspond to a chord. Thus, "if a perfumer desires to make a bouquet from primitive odours he must take," he said, "such odours as chord together; the perfume will then be harmonious." According to this classification he found that the chord, say, G G D (bass) F G B (treble), gave a bouquet of chord G, pergelaria corresponding to the first G in the bass, sweet-pea to the next G, violet to D, tuberose to F, orange flower to G, and southernwood to B, the comparison of odour to note being made by a personal estimation of the amplitude of vibrations. Similarly a bouquet of chord C was made up of santal, geranium, acacia, orange flower, and camphor (C C E G C), and a bouquet of chord F consisted of musk (F), rose (C), tuberose (F), tonquin bean (A), camphor (C), and jonquil (F). It is evident that this classification suggests octaves of odours, and we are reminded of the law of octaves in light, sound, and chemistry. In Dr. PIESSE'S gamut of odours we find, for example, at the lower end of the scale the note B corresponding to clove, and the octave B above gives stocks and pinks, and the higher octave B cinnamon. The keen sense of smell will recognise a similarity of odours here, just as the musician recognises the musical octaves. Other examples of analogy could be given which show an interesting relationship where a keen faculty of recognition exists between odours and sounds, and we are led to wonder how far we are merely the subjects of vibrations produced in different ways which now affect the eye, now the ear, and now the nose, and so forth. Why, however, some vibrations soothe while others irritate it is difficult to say, but certain it is that sounds can be bad as can colours and odours. There are discords and harmonies, beauty and ugliness, stinks and fragrance. It is just possible that, by the further study of odours, they may ultimately receive some such scientific divisions as do sounds and colours. Mr. WILLIAMS, whose communication has prompted these observations, makes a suggestion which may afford a useful starting point. H proposes a preliminary classification of the primary odours, selecting such bodies as (1) ammonia; (2) sulphuretted hydrogen; (3) bromine; (4) valeric acid (5) ether; (6) menthol; (7) camphor; (8) artificial musk; and (9) nitro-benzol. Assuming that the category and its members are well chosen, the next thing to be done would be to find a name for each of these odours, apart from the names of the substances. This name would then be generic in character and capable of being applied to a number of substances, just as red is applied as the distinguishing colour of sunset, fire, bricks, blood, and so forth. On the ready acceptance by the unscientific public of these generic names—that is, on a widespread feeling that each generic name characterises naturally the class of smell to which it is attached, would popular adoption of such a scheme depend.

The difficulties of making a classification of odours are thus seen to be great. We know how the vibrations of sound and light are set up and how they are conveyed, but in the case of odours we do not know with any certainty the origin of the wave or the method of its transmission. Apparently, the presence of oxygen or air seems to be necessary before the sensation of smell can be experienced, and the same process of communication, whatever it may be, is probably at work when the palate is respon-There is room here for much research, and the subject is of considerable practical importance, since so many of the creature comforts of this life obtain a valuation based upon their æsthetic qualities which are chiefly that of flavour and aroma. A penny cigar may be all genuine tobacco, but it does not, as a rule, afford the same degree of gratification to a smoker that an expensive Havana cigar does, nor does the haddock give the palate the same satisfaction as the turbot. Æsthetically speaking, calves' head is an appalling substitute for turtle, but from a dietetic point of view there is probably little difference between them. Similarly, elegance is sought after in wines, but there is very little difference between the chemical composition of a vin ordinaire and a Château Lafite. We pay much for a satisfactory appeal to the eye, the ear, the nose, and the palate, and all medical men know that to do so is good sense and not sensuality. A classification of odours would be of distinct value to medical men both in debate among themselves and in their relations with their patients.

Medical Parliamentarians.

ALTHOUGH we are able to disassociate ourselves entirely from party politics, it is our duty to follow with the closest attention the doings both of the House of Lords and the House of Commons. Those Parliamentary proceedings which immediately concern the physical and moral health of our countrymen or directly affect the welfare of the medical profession may seem to interest us most deeply, but such are the ramifications of medicine to-day that there is hardly a Bill brought forward or a policy advocated in which some medical bearing may not be detected, in which medical interests are not involved. It is therefore desirable that a certain number of medical men should be returned to the House of Commons, so as to keep the legislature informed of the right scientific view on an enormous number of points, and there can be no fear that the return of such men would lead to any infringement of popular rights in deference to the views of special pleaders. A medical Member of Parliament, though the most accomplished speaker in the profession, and even in the House, can hardly hope that he will find the opportunity to persuade the legislature immediately to proceed penally against unqualified practice or to pass hastily any other measure which might have the complexion of class protection. But his presence can make itself felt, as can the influence of all earnest medical parliamentarians. By work on Committees, by personal intercourse with their of the road, he neglects to look to his right as well, he

fellow Members, and by availing themselves of proper opportunity of debate, medical Members of Parliament may diffuse a knowledge of the high ideals of preventive medicine and of the real public danger of unlicensed quackery in such a manner that men of party influence, and even Cabinet Ministers, may feel constrained to adopt at least something of the medical point of view. It cannot be doubted that the position of the President of the Local Government Board, acting as he does as the Minister of Health, is considerably strengthened by the presence of a few medical men in the House, especially when he finds it his duty to legislate against some insanitary but profitable trade. This being the case, a medical candidate for Parliament, if in other respects than in his calling he be the right sort of man, is always worthy of the suffrages of medical practitioners, and the question has to be considered seriously whether such a candidate might not well be supported by his professional brethren irrespective of his political party, and whether, provided he would give them a pledge to use his best endeavours in the House of Commons in the cause of medicine and of public health, he might not be frankly adopted by medical men. We do not put forward this view with any great approval, for medical men are citizens first and practitioners afterwards. To ask a voter, because he is a medical man, to give his vote to a medical candidate who thinks completely differently from himself on important constitutional questions is unreasonable. It can be claimed for medical men that their ideals are progressive and altruistic in a way that the ideals of no other professions are, upon which it follows that if a medical candidate is representative of professional views he is a good candidate whichever side of the House he may elect to sit. It does not follow that a voter having strong political convictions should sink them to return a medical candidate, for the general considerations must come before the particular. But where a medical man's vote as a citizen can assist a medical candidate especial energy should be put into the process.

Annotations.

"Ne quid nimis."

MOTOR ACCIDENTS IN LONDON.

WE observe that recently a medical man, Dr. T. Woulfe Flanagan, was publicly thanked by the magistrate sitting at Bow-street police court for coming forward to give evidence in a case in which the driver of a taxicab had knocked down two road-cleaners by driving recklessly on the wrong side of a street refuge. A fine of £3 was inflicted on the defendant as, apparently, there had been no previous complaint against him, and a like punishment was awarded to another man who was convicted and sentenced on the same day and by the same magistrate for a similar offence. The danger arising from drivers, and not infrequently from cyclists, passing on the wrong side of street refuges in order to save themselves from delay is obvious. The foot-passenger who in crossing a street has reached a refuge instinctively looks to the left, the side from which all traffic moving along the part of the road yet to be traversed should come, but if, trusting to drivers obeying the rule

may at any time be run into by a comparatively noiseless vehicle the driver of which is in too great a hurry to adhere to his proper course. In the case in which Dr. Woulfe Flanagan gave evidence the injured men were not ordinary pedestrians, and were not severely injured, but Mr. Curtis Bennett, in commenting on the risk attendant upon passing on the wrong side of refuges, expressed himself as fully alive to the prevalence of the practice, and announced his intention to deal severely with those indulging in it if it were not discontinued. The danger is increased by the ease with which a motor vehicle can be deflected from its course without slackening its speed, a characteristic which renders it a far greater source of risk to the public than a horsed carriage or cart, and this may be observed not only when a motor-car is dodging in and out of the traffic at a street refuge, but even more conspicuously when it turns a corner. Reckless and dangerous hurrying round corners may be seen at almost every spot in London where streets intersect, er lead into, one another. To take a well-known turning as an instance, anyone who walks up the north side of Conduitstreet on his way from Bond-street to Regent-street will find as he prepares to cross the end of George-street that motorcabs and cars travelling towards Hanover-square from Bondstreet are tempted by the angle, which happens to be greater than a right angle, to negotiate it at full speed closely shaving the kerbstone. It is quite easy and perfectly safe for them to do so, but extremely dangerous to the unwary pedestrian who may not have looked behind him and is unable to check himself on the edge of the pavement. The mention of Hanover-square reminds us that a fatal accident took place there on the night of Nov. 26th. The verdict of a coroner's jury has since exonerated from blame the driver of the taxicab which ran over and killed Mr. W. H. Stallard, a solicitor, and we therefore only refer to the death as illustrating the danger of this class of traffic generally and because on this occasion also a medical man, Dr. David Walsh, gave evidence as an eye-witness of the occurrence. It has additional appositeness, because at the inquest Dr. Walsh informed the coroner's jury that his own care in crossing where the deceased met his death was in a measure due to the fact that a few weeks previously he had himself been run over, with the result that he was still lame. His experience of personal injury and of witnessing the death of another within a few weeks from the same cause, combined with the statistics published recently by the police with regard to street accidents and commented upon widely in the newspapers, should tend to rouse public opinion to the serious and increasing danger from the abuse of their privileges by motor-car drivers. If a census of accident cases due to this cause now being treated in the London hospitals were to be taken it would add some instructive figures. On a recent date, we are informed, no less than nine beds were occupied at St. George's Hospital alone by victims of the horseless carriage, while six more were to be found in the wards at Charing Cross Hospital. It is for the public to protect itself in the matter, and one way in which it can do so is to follow Dr. Woulfe Flanagan's example and to aid the police in their difficult duty of regulating the traffic. We often see charges of all kinds in our police courts criticised as "resting on police evidence only," as if this showed that they were of a trivial character, or had escaped the notice of any but professional witnesses. Members of the public whose position would carry weight before the magistrate are sometimes those most ready to blame both magistrates and police for affording inadequate protection to such as themselves; yet they are the least willing to spend their doubtless valuable time in rendering to the executive that support which it would most gladly welcome. It was mentioned that at the hearing of the first case commented on above the of England. The many points of resemblance between the

Highways Protection League was represented by counsel watching the case, and the matter is one in which such an organisation can do much by stimulating the energy and public spirit of individuals.

THE HUXLEY MEMORIAL LECTURE.

Professor Bateson, in his address on Mendelian Heredity which he delivered on Dec. 1st last at Birmingham as the Huxley Memorial Lecture, said that on such an occasion it was natural to look back on the part which Huxley had played in the development of the theory of evolution. Though an enthusiastic advocate of Darwin's views Huxley had always retained an article of faith excluded from the orthodox Darwinian creed. To Huxley it had appeared that the importance of specific and discontinuous variationmutation, as it is now called-must be far greater than Darwin was disposed to admit. When, some years ago, Professor Bateson published evidence tending to support the mutation theory, it had been no small encouragement amongst much hostility to receive from Huxley a letter of sympathetic approval. And now, said the lecturer, time had provided abundant material justifying Huxley's expectation-indeed, the doctrine of mutation had now more to fear from its uncritical adherents than from direct opposition. The change had come about chiefly through the recognition of Mendel's work and the perception of the processes of heredity and variation thus acquired. Posterity would undoubtedly regard Mendel's discovery as one of the greatest contributions ever made to man's knowledge of nature. The essential fact of Mendelism was that the forms and qualities of living things can in numberless examples be proved to depend on the presence of definite elements or factors, and that those factors are distributed among the germ-cells according to predicable systems, which could be illustrated by reference to a variety of phenomena in plants, animals, and man. From a study of the peculiar mode of transmission of colour-blindness and other "sex-limited" conditions, the conclusion was reached that the distinction between the sexes was determined by Mendelian factors distributed on a definite system. In another respect Mendelism bore on Huxley's views. Huxley had often pointed out that the sterility of hybrids was a serious difficulty in the way of Darwin's theory. The Mendelian method was beginning to show the nature of this sterility, and further inquiry would perhaps completely elucidate it. In certain cases it was possible to suggest the chemical nature of Mendelian factors with some confidence. Professor Bateson's general conclusion that with the progress of this analysis the piological sciences were passing into a new phase will be opposed by no one. His word of warning against the too ready acceptance of violent generalisation made by enthusiasts will be noted. for any attitude of reasonable criticism is sometimes described by Mendelians as fossilised devotion to a scientific scheme laid down by Darwin.

DISCOVERY OF TASMANIAN SKULLS.

Professor R. J. A. Berry, of Melbourne University, and Dr. A. W. D. Robertson have made a very remarkable and unexpected discovery of skulls belonging to native Tasmanians. Some 33 years ago "Lalla Rookh," the last of her race, died, and with her passed out of existence not only the most primitive civilisation but the most primitively constituted people that anthropologists have any knowledge of. Last year Sir William Turner made an inventory of all the remains known of this race and was able to compile a list of 79 skulls, by far the richest collestion being in the museum of the Royal College of Surgeons remarkable people who inhabited Europe in palseolithic times—two additional examples of which have been recently discovered in France and largely discussed in the popular press—and the native Tasmanians have made clear to anthropologists that much can be learned of the very earliest inhabitants of Europe by studying the native races of Australia. Hence the importance of Professor Berry's success in collecting from various sources—former burial grounds, private collections, and museums—42 additional Tasmanian skulls, all of which he has good reason to regard as authentic. The description of his collection will occupy some time, but there can be no doubt that the publication of his investigations will provide a valuable welcome addition to our knowledge of a most interesting past race.

RESEARCH DEFENCE SOCIETY.

THE work of this society is now being widely extended by the formation of branch societies in all parts of the kingdom. The Brighton and Sussex branch have arranged for a public meeting to be held on Monday next, Dec. 13th. at 3 o'clock in the Royal Pavilion, Brighton. Among the speakers will be the Earl of Cromer, President of the Society, and Sir Arthur Conan Dovle, President of the Brighton and Sussex branch. The patrons of this branch are the Duke of Devonshire and Lord Leconfield, and the branch has already a large number of members. We sincerely hope that the work of the Research Defence Society will continue to be well supported by members of the medical profession. The society has already more than 2700 members and more than 100 associates, and is fulfilling a very useful purpose in bringing about a better condition of public opinion as to the objects and the character of experiments on animals, and as to the conditions under which they are made in this country, under the restrictions of the Act.

ERYTHEMA DUE TO THE APPLICATION OF COWS' MILK.

In the Yale Medical Journal for November Dr. H. M. Steele has reported a case in which the application of cows' milk to the infant skin produced a curious effect. The patient was a female child, aged 6 months. She was a twin whose sister had died from marasmus in the fourth month. She was nursed by the mother for six months, during which she did well except for an attack of mastitis and otitis media in the fifth month, from which she completely recovered. As the mother was worn out from the twin sister's illness and death and had two attacks of influenza, this child was partially weaned, although she was doing well and had gained 12 ounces in the preceding two weeks. She was put on modified fresh cows' milk, which was obtained from a model dairy. After taking about an ounce a bright red rash appeared about the mouth, and on the cheeks where some of the milk had been accidentally spilled. little later she vomited, but she seemed ill in no other way, and the rash disappeared within an hour. Her father took some milk from the bottle in which the milk was delivered and rubbed it on the baby's forehead. The same rash was produced in about the same time, but lasted only half an hour. Dr. Steele had the milk analysed, but received the report that its constituents were in the proper proportion and that it contained no preservatives. On his own skin it produced no effect and inquiry among many patients taking the same milk did not show any similar case. On the following day the rash was produced both by application of the same milk and of milk from another dairy, but not by the mother's milk. The rash was not produced by ingestion of milk, but only when the milk was spilled and came in contact with the face. There was only slight regurgitation of milk on this day. The lactose was

removed from the modified milk mixture, the milk was peptonised, and finally was boiled, but none of these changes made the slightest difference in the production of the rash. The rash at first appeared with perfect regularity about 15 minutes after milk touched the skin, and lasted at first an hour. Then its duration gradually diminished until after 21 days it ceased to appear. The rashwas bright red and not raised. Sometimes it was sharply circumscribed; at others it faded with a pink edge to the normal skin. It corresponded exactly to the area touched by the milk. It never resembled urticaria or appeared tocause itching. Dr. Steele does not attempt to explain thisourious effect of the application of milk to the skin. It evidently was due to idiosyncrasy to some normal ingredient of the milk. It could not have been due to an abnormal ingredient, for cow's milk from any source produced it. The gradual acquisition of immunity seems to us of considerable interest, and due to the ingestion of the milk. Evidently the administration of the offending ingredient gradually produced tolerance. Dr. A. T. Schofield has recorded in our columns a case of idiosyncrasy to white of egg in which tolerance was similarly induced.1 The patient was a boy, aged 13 years, who could not eat egg in any form without the production of salivation and profuse urticaria. He was given doses of egg so minute that they produced no symptoms, and the dose was gradually increased until complete tolerance was established to eggs in any quantity. Dr. Steele's case differs from thisin the fact that the idiosyncrasy was a local reaction due tolocal application, not a general reaction due to internal administration. Idiosyncrasy of the former type is much the rarer. Some years ago we discussed a peculiar eruption due to contact of arterial blood with the skin during operations described by Mr. Marmaduke Sheild, which he termed "blood erythema." We concluded that the erythema was an example of idiosyncrasy and was similar to the urticaria. produced in some persons by the application of yelk of egg to the skin. The analogy of blood erythema with the milk erythema is obvious.

NOVEMBER AT HOME AND ABROAD.

Ir the figures given below are compared with those for November which were published in THE LANCET a year ago, it will be seen that at all the places represented in the table except those in Italy the mean temperature was lower than during the corresponding month of 1908. The divergence was considerable nearly everywhere, and at Biarritz it amounted to as much as 8°. In these islands the weather was cold for the time of year and also remarkably dry and sunny, the records of sunshine in many localities being about 50 per cent. above the average, and at a few places in the south of England nearly 100 per cent. above. Such a bright November has not been enjoyed in some parts of the kingdom for at least 30 years. In central Ireland and a large part of Scotland the frost experienced between the 15th and 20th of the month was the most severe ever recorded in November in those localities, and the records go back to nearly 40 years. In the central and eastern counties of Scotland the thermometer exposed on the grass descended to about zero, or a few degrees below it, and at Balmoral the screened instrument four feet above the ground fell to within three degrees of zero. London and England generally were milder than Paris, Berlin, and Brussels, and also less rainy, but, as is usually the case in November, the South of France was milder than the mildest part of the United Kingdom. while the southern half of Italy was milder still. At Malta. Algiers, and Palma the mean temperature was almost

¹ THE LANCET, March 7th, 1908, p. 716. ² THE LANCET, March 20th, 1897, p. 821.

identical with that generally experienced in July and August in the south and south-east of England. Frost occurred on several occasions on the Riviera and at Biarritz, as well as in Italy as far south as Rome, and it is worthy of note that both Nice and Biarritz registered a lower minimum temperature than London, Brighton, and Weymouth. The temperature after sunset was no higher at Nice than at Scilly while at Biarritz and Florence it was lower, but those southern resorts enjoyed a warmer day temperature. especially the case during the first half of the month, when the sheltered thermometer rose to 55° or above almost every day, and on some occasions went to 60° or beyond. At Biarritz there was also a very warm period about the The mean diurnal range of temperature was small generally. At Malta and Lisbon it was no greater than 7°, and, owing to the cold days, only 8° at Berlin. At many places on the shores of the Mediterranean it was rather large, and moderate in the south and south-west of England.

MOUTH DISINFECTION AND DIPHTHERIA.

RECENTLY we drew attention to the importance of mouth disinfection. This need is particularly felt in ships where men live more closely in association with one another than they do anywhere else. Special attention is given to this risk, we learn by recent publications, in the American and German navies. Dr. J. D. Gatewood in his recent work on "Naval Hygiene," mentions this risk in relation to syphilis, tuberculosis, diphtheria, influenza, pneumonia, measles, enumps, and scarlet fever. There is a special source of danger in the American navy, as drinking cups, used by all, are attached to the ordinary drinking tanks on the living decks of their ships. To obviate risk some

of their ships keep these drinking cups lying in a formalin solution, while others have adopted an expensive mechanical device to secure that men shall always drink from running water. In the last sanitary report of the German navy 24 cases of diphtheria are reported, all but 10 of them isolated cases. These 10 occurred in certain messes in a training ship. The patients were at once removed, their plates, knives and forks, and their clothing disinfected. Still cases continued to occur. It appeared likely that the boys who returned from hospital were, in spite of careful mouth disinfection in hospital for a week after recovery, still "carriers," and that they must be infecting the mess utensils. It was decided regularly to boil these mess utensils and to make all members of these messes gargle daily, under supervision, with peroxide of hydrogen. The effect, we learn, was striking—the epidemic ceased.

THE STANDARDISATION OF DISINFECTANTS.

WE have received a number of communications from manufacturers of disinfectants and others referring to the report of our Commissioners on "The Standardisation of Disinfectants" which appeared in the issues of THE LANCET of Nov. 13th, 20th, and 27th respectively. We, of course, welcome any comments upon our Commissioners' work from those who possess either a theoretical or a practical knowledge of the subject, our single concern being to arrive at the facts of the case. We have handed the various documents to our Commissioners, who, we hope, will deal with them shortly.

FRACTURES OF THE CLAVICLE.

An immense amount of ingenuity has been expended in devising methods of treatment for fractures of the clavicle, and Gurlt has recorded some 70 different methods. The mere fact that so many devices have been invented is in itself sufficient proof that the object to be attained is difficult of realisation and it also casts doubt on the efficiency of any of the methods employed. The latest candidate for adoption has been brought forward by Dr. W. F. Westmoreland of Atlanta, Georgia. In the September number of the International Journal of Surgery he points out that the clavicle is peculiarly liable to fracture, more than 50 per cent. of a long series of fractures being fractures of this bone. The shape of the clavicle appears to be specially intended to give it elasticity, but the frequency with which the bone is broken shows that this elasticity is hardly sufficient for the purpose, while this same frequency causes us to apologise for recapitulating in the interests of clearness the well-known story of such fractures. In the very large majority of the fractures of the clavicle the injury is produced by indirect violence, the bone breaking about the middle at the junction of the two curves. The direction of the fracture is nearly always oblique, and in the more frequent forms the outer end of the sternal fragment is tilted up and overrides the inner end of the acromial fragment which is displaced inwards, giving rise to very definite shortening. Sometimes the fragments do not separate, the broken ends being turned slightly upwards and backwards so that an angle is formed at the seat of fracture. At the present time Sayre's dressing or some modification of it is the most popular treatment, but it cannot be said to be free from objections, and pain, pressure, and irritation of the skin are the chief. Dr. Westmoreland considers that in Sayre's methods the fracture is rarely reduced, and even when reduction is effected he believes the fragments slip while the dressing is being applied, and even if the reduction has been carried out and the dressing accurately applied in a few days he tells us that displacement occurs anew. Most of the text-books on surgery suggest that

the best and most cosmetic result is attainable by keeping the patient in bed and allowing the arm to fall backwards. We agree with Dr. Westmoreland that such a plan of treatment must be very difficult to carry out, for few people will submit to complete confinement to bed for such an injury, even if the reward be the healing of a fracture without deformity. The method advocated by Dr. Westmoreland is this. The patient is laid on a table flat on his back, the arm lying comfortably by the side; if allowed to remain in this position for even a few minutes the fracture usually reduces itself. The patient is then drawn over the end of the table until the scapula clears it, the patient's head being supported by one hand of an assistant and the back by the other. If the fracture is even now not reduced the arm is slightly abducted and gently pushed a little towards the head and the acromion process is pushed back approximating the scapulæ. This, he claims, always reduces the fracture. With the patient in this position a plaster-of-Paris splint is applied. Before the patient is placed upon the table a closely fitting vest is put on and over it the plaster bandage is wound. The plaster splint should come well down over the ribs so as to support the shoulder without the edge of the plaster on the opposite side of the body pressing into the ribs, which will happen if the body part of the splint is too short. The position of the arm of the injured side is immaterial, but it is better to abduct the arm just enough to allow the bandage to be passed easily under the axilla. Dr. Westmoreland has treated by this method 16 patients, and none has complained of any discomfort, though five of them were sent to him on account of their inability to wear Sayre's dressing. With this splint on children may run and play about as much as they like. The method seems to be deserving of trial.

AN OUTBREAK OF JAUNDICE WITH SYMPTOMS OF GASTRO-INTESTINAL CATARRH.

THE occurrence of jaundice with fever and gastro-intestinal disturbances in a number of persons at the same time is now well known. It presents several types, varying from simple catarrhal jaundice with fever to the most severe forms of icterus with prostration, acute intoxication, nephritis, destruction of the liver, and death. It appears to be due to an infection of the gastro-intestinal tract, possibly combined with infection of the bile-passages and even of the liver. Its bacteriology is imperfectly known. In the Johns Hopkins Hospital Bulletin for October Professor Lewellys F. Barker and Dr. F. J. Sladen have reported a small outbreak which occurred in Baltimore city jail and affected six out of 700 prisoners. Their ages varied from 21 to 29 years. The first patient was taken ill on Nov. 26th with a chill and vomiting. Headache was felt next morning and persisted for a week. During this time he suffered from pain in the abdomen, calves, and hips. Jaundice did not appear until the sixth day and the stools then became acholic and frequent. The second patient was taken ill on Dec. 1st, the third and fourth on Dec. 3rd, the fifth on Dec. 5th, and the sixth on Dec. 9th. The onset was sudden, with chill and headache in three cases. Severe muscular pains occurred in three cases. Nausea, vomiting, diarrhoa, and abdominal pain occurred separately or in combination at one time or other. The jaundice was obstructive in type and appeared on the second, fifth, sixth, and seventh days respectively in four of the cases and on the eighth day in two cases. The liver was enlarged and in some cases the spleen also. Leucocytosis was present and in one case was as high as 23,200; polymorphonuclear neutrophiles predominated. The only other abnormal condition found in the blood was bile in the plasma-Cultures were made from the stools on agar agar, but showed only the bacillus coli and the ordinary intestinal flora. On picric-acid-brilliant-green agar small opalescent colonies were

obtained in the time allotted by Conradi to the typhoid and paratyphoid bacillus, but they resembled in cultural characters the colon bacillus. Cultures made from the blood yielded no growth. The blood serum was examined for specific agglutinins; in all cases negative results were obtained with the typhoid bacillus, but positive with the paratyphoid. Some writers depreciate the value of agglutination in this disease on account of the presence of bile in the blood, to which they attribute the phenomenon. However, Conradi has recently emphasised the fact that bile does not agglutinate the typhoid or paratyphoid bacillus. Careful control experiments confirmed the conclusion that specific agglutinins were present in these cases. The patients were quartered within the same walls, but their cells were well separated. Five of them ate in the same dining-room. Evidently the source of infection was the food or the drinking water. No particular article of food was incriminated, but the meat was suspected, as many outbreaks of meat poisoning appear to be due to gastro-enteritis produced by the bacillus paratyphosus. In 1886 Weil of Heidelberg first described this form of jaundice, to which his name has been attached by the Germans, who considered it a separate clinical entity, but recent observations point to the conclusion that Weil's disease is only a form of a more general icterus infectiosus.

LEAD-POISONING FROM A SODA-WATER FOUNTAIN.

In the Boston Medical and Surgical Journal of Nov. 4th Dr. A. L. Patch and Dr. E. W. Taylor have reported a case of lead-poisoning from an unusual source. A Russian Jew, aged 55 years, was admitted into hospital on August 22nd, 1908. His wife and one daughter were ill from leadpoisoning and another daughter had recovered from the disease. For the past two years the patient's health had been failing. Two months before admission he had an attack of severe colic with hæmaturia and became very constipated, and the pain continued. For a few days his mind appeared to be affected; he was forgetful and could not complete his sentences. On admission he was semiconscious and difficult to rouse. There was the lead line on the gums. The knee-jerks were normal and there was no evident paralysis. The skin was pasty and the mucous membranes were pale. The pulse was of low tension. Fine, moist rales were heard at the bases of the lungs. The ankles were slightly ædematous. The urine contained a trace of albumin and a few hyaline and fine granular casts. It was found that 18 months previously the patient bought a second-hand soda-water fountain. In April, 1908, the block-tin piping in the fountain became leaky and he substituted lead piping for it as this was less expensive. In May he began to feel weak and his power of lifting became weaker. In the following month he had crampy pains in the abdomen and limbs. His only drinking water was obtained from the soda-water fountain. Later wrist drop and atrophy of the supraspinati and of the muscles of the arms developed. Some of the atrophied muscles gave the reaction of degeneration. Under potassium jodide and galvanism he recovered. The soda-water in the fountain gave a marked black precipitate with hydrogen sulphide. Careful examination of the patient's house revealed no other source of lead poisoning.

THE excellent collection of English coins, chiefly crown pieces, made by our late editor, Mr. Thomas Wakley, and his numismatic library, were sold by auction at Sotheby's this week. The three days' sale realised £2896.

THREE lectures on Some Problems Relating to the Evolution of the Brain will be delivered in the theatre of the Royal College of Surgeons of England on Dec. 13th, 15th, and 17th, at 5 o'clock each day, by Professor Grafton Elliot Smith, M.A., M.D., Ch. M., F.R.S. (Arris and Gale lecturer).

THE Medical School of King's College Hospital, which was by the King's College, London (Transfer), Act separated from King's College, has been admitted as an independent body to the status of a school of the University of London in the Faculty of Medicine.

A TELEGRAM from the Governor of Mauritius to the Secretary of State for the Colonies reports that 33 cases of plague with 13 deaths occurred in the week ending Dec. 2nd.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

DENTAL JUBILEE DINNER: ADDRESS BY MR. BUTLIN.

A DINNER was given by the President and Council of the Royal College of Surgeons of England at the College, Lincoln's Inn-fields, on Thursday, Dec. 2nd, at which the jubilee of the granting of the Dental Charter to the College was celebrated. Mr. Butlin, who presided, was supported by many members of the Council of the Royal College of Surgeons, and amongst the company were Mr. William Hern, President of the Odontological Section of the Royal Society of Medicine, Mr. H. R. F. Brooks, President of the British Dental Association, Sir Richard Douglas Powell, Mr. R. Bligh Wall, Master of the Society of Apothecaries, Sir William S. Church, Mr. C. S. Tomes, Mr. Morton A. Smale, and the Editors of the British Medical Journal, the Bratish Dental Journal, and The Lancet.

On the plan of the tables was printed the text of the memorial presented to the President and Council of the Royal College of Surgeons on Dec. 13th, 1855, by 18 dental practitioners asking for the institution of a diploma in dental surgery. Other information given on the same paper included the date of the charter enabling the College to grant licences in dental surgery, to wit, Sept. 8th, 1859, the names of the examiners constituting the first and present examination boards in dental surgery, and the extract from the College register showing that on August 1st last there were 2183 licentiates in dental surgery, of whom 14 hold the Fellowship and 238 the Membership of the College. Another interesting document was the menu-card, showing, as it did, a baron of beef as the pièce-de-résistance of an excellent repast.

After the loyal toasts had been given by the PRESIDENT,
Mr. BUTLIN rose to propose "The Dental Profession" in
the following terms: When it came to the knowledge of the Council of this College that 50 years had elapsed since the Dental Charter was granted to the College, it seemed to the members of the Council fit that so important an event should be celebrated. After consideration they came to the conclusion that this might best be done by offering a dinner to the members of the dental profession in the precincts of the We should have liked to entercain all our licentiates of dental surgery, but our space is limited, and we were obliged to confine our invitation to what may be called the representatives of the profession of dentistry. Our idea seems to have commended itself to you, for we have the pleasure of welcoming here a large number of distinguished members of your profession. I wish you, in the name of the Council, a hearty welcome, and I only regret that the time which has passed since the events which led to the granting of the Dental Charter is so long that we have no one here to-night who took such a share in those events as would have entitled him to tell us of them from his own personal re-

At a recent meeting of our Council Sir Henry Morris said that the condition of dentistry 50 years ago was "chaotic," and I am sure he did not use too strong an expression. For a study of the literature of the time has taught me that dentistry was practised by all manner of persons. For instance, the chemists and druggists often

collection.

associated the practice of dentistry with their ordinary business. And Clause LV. of the Medical Act of 1858 places chemists, druggists, and dentists in the same category. Mr. Walter Brindley of Sheffield writes in 1857 (British Journal of Dental Science, i, 223): "For instance, in the last Directory for the town of Sheffield there is a certain practitioner put down as 'brass-turner and dentist.'" And Mr. Donaldson Mackenzie writes to the same journal in 1859 (iii., 151) to tell how, in his travels about England, he had studied the position of dentists, and "found one sexton, one or two delectable specimens of our present system of education, who could not sign their own name, and one doing a tolerable practice who could neither write nor read." In truth, a man might serve a dentist one day in the capacity of servant or mechanic, and might set up as a rival to his master on the following day, provided he were clever enough to persuade the public of his capability. And he was free to advertise himself to what extent he chose. Even then, however, they did things better in that respect in France. For I have come across a delightful specimen of the art (in a letter from Cosmos in the British Journal of Dental Science, iii., 47), which runs as follows: "Grande Maison de Dentition. Mons. et Mad. de S. announce that they set teeth with diamond pivots and stop teeth with emeralds." And they further remind the public that "it is useless to speak much of their new mode of extraction, as the process is entirely by steam, and is consequently the most efficacious of any system practised by other dentists." No wonder that such ill conditions as these moved 18 gentlemen practising dentistry in the year 1855 to meet and consider what could be done to ameliorate them. Their consideration resulted in the composition of a memorial to the President and Council of this College. I have had the memorial printed with the 18 names attached to it, that each one of our guests may possess a copy of it if he pleases. It will be seen that two motives are expressed in the memorial-the condition of dentistry in England and the much better position of dentistry in America. During the last 20 or more years I have often heard the superiority of American dentists vaunted by rich persons in London, and I regarded this as a fashion of modern times, like the determination of such persons to consult fereign specialists in preference to their own specialists. I had no idea that American dentistry had really been so superior to English dentistry before the granting of the Charter. At the present time there is no reason to believe that American dentistry is superior to English dentistry, or that the best English dentists are inferior to the most skilful American dentists. But in 1855 there can be no doubt that America was far ahead of England in the education and position of dentists. The memorial was sent up to the College in December of the year 1855 and was presented to the Council at its meeting in January, 1856. It was referred to a committee of six members of the Council, with Mr. Green as their chairman. In February, 1857, the memorialists addressed a letter to the College asking whether anything, and if so what, was being Mr. Edmund Belfour, the secretary, replied to the effect that the legal advisers of the College had been consulted and had given it as their opinion that it was not competent for the College under its present Charter to do what the memorialists had suggested. It would, therefore, be necessary to apply for a special Charter, and the Council could not do that while legislative measures were before Parliament because they were in conference with, and pledged to, other medical corporations in respect to these

In the course of the next year these legislative measures produced the Medical Act of 1858, in which Clause XLVIII. provided that "It shall, notwithstanding anything herein contained, be lawful for Her Majesty, by Charter, to grant to the Royal College of Surgeons of England power to institute and hold examinations for the purpose of testing the Fitness of Persons to practise as Dentists who may be desirous of being so examined, and to grant Certificates of such Fitness." The earliest possible advantage was taken of this clause, and the Dental Charter was obtained in September, 1859, just 50 years and a few months ago. The first board of examiners—Mr. Lawrence, Mr. Green, and Mr. Arnott for the surgeons; Mr. Thomas Bell, Mr. John Tomes, and Mr. Arnotd Rogers for the dentists—was soon afterwards appointed, and in the following year (1860) the first examinations were held.

In that year no fewer than 111 candidates took the diploma—a remarkable proof of the earnestness of the leaders of the dental profession, for some of those who passed the examination were qualified in medicine and surgery, and some had been leading men in their profession years before the granting of the Charter. The number of those who took the Licence in the first year is the more remarkable when it is remembered that the total number of dentists practising in England at that time was estimated at from 1200 to 1500. The Dental Act, which made qualification as necessary to a dentist as it is to a medical man, was not passed until 1878.

Such is the official account of the transaction, and I would now like you to hear the human side of it. With the exception of the long delay in obtaining the Dental Charter there might seem nothing of interest in relation to the movement. In the minutes of the Council and in the official letters there is no trace of a hostile spirit. But it was far otherwise outside the College walls. no sooner did a number of the rank and file of the dental profession know of the memorial than a meeting was called, speeches were made against the proposal, the independence of the dental profession was affirmed, and an association was formed to which the high-sounding title of College of Dentists was applied. The memorialists, on their part, were not content with what they had already done. They also took counsel with their friends, and, without delay, established the Odontological Society of London, which at this moment forms the Odontological Section of the Royal Society of Medicine. Thus there was on the one side the Odontological Society with the policy of combination with the College of Surgeons; on the other side, the College of Dentists and independence. I think the College of Dentists had, perhaps, the larger number of members, but the society had the very pick of the profession. Its meetings were from the first characterised by high scientific value, and although surgeons occasionally read papers at them, the society contained so many men of ability-many of them qualified in medicine and surgery, and more than one of them a Fellow of the Royal Society—that there was no need of outside help. The College of Dentists, on the other hand, could scarcely boast of one man of high position or distinguished ability among its ranks. But, nothing daunted, it called in outside aid, established courses of lectures, and actually obtained the services of Hulme, Benjamin Ward Richardson (a host in himself), Ecichsen, and Spencer Wells. With the rise and growth of the two parties, there seen arose, also, two organs of the press, the British Journal of Dental Science, which took the part of the Odontological Society and combination with the College, and the Dental Review, which took that of the College of Dentists and independence. They went at it hammer and tongs, and a fine din there was. Every month, when the journals appeared, the sparks flew; and although no bones were, so far as I know, broken, there were furious attacks on reputations, and you may be quite sure that our College was not left out in the cold.

The long period of apparent inaction on the part of the College afforded, as you may suppose, ample opportunity to the shafts of the enemy. The College never intended to do anything or to grant the petition of the Memorialists: it held them in ridicule: the Council were far too proud to be mixed up with the dentists. Such was the burden of the opposition orators and of the Dental Review. The grant of the Charter must therefore, I think, have fallen heavily upon them. I have no doubt that some of the members of the College of Dentists consulted the Review as to the course they were to take; for that journal, in its issue of October, 1859, advises: "Do nothing." 'Then the hybrid Charter will do nothing." 'The College of Surgeons will find their work much too warm to be pleasant, &c. became apparent that the combination party and the surgeons were in deadly earnest, and that the hybrid Charter would do a great deal. Nevertheless, the College of Dentists and the opposition still kept up their tail, and the College of Dentists seemed to me, as I read the articles and communications in the *Dental Review*, to be going quite strong, when, to my astonishment, an extraordinary event occurred. For, on May 4th, 1863, the Odontological Society of London raised its head, opened its mouth, and swallowed the College of Dentists whole, so that no man saw it more. The only effect which this miraculous

performance seems to have produced upon the society was that it swelled considerably from accession to its members, and that it changed the form of its tail, for it became from that time the Odontological Society of Great Britain. I can tell you there was great jubilation that evening. rooms of the society were filled. Mr. Arnold Rogers was there, in spite of illness. Mr. Imrie, the President of the College of Dentists, was there, but not able to make a speech on account of an "affection of his throat," and so his speech was delegated to Mr. Samuel Rymer, who had fought the battle valiantly for independence, but had also been largely instrumental in conducting the negotiations between the society and the College of Dentists to a successful issue. He died only last year. There were congratulations and a great shaking of hands, and that night and in that fashion the opposition came to an end.

Between 1855 and 1860, or nearly within that period, the two great dental hospitals were founded. Two schools of dentistry were established. The Westminster General Dispensary also made arrangements for the teaching of dental students. The dental journals which I have quoted made their first appearance; and I think what must be called the first scientific treatise on dentistry was published from the pen of Mr. John Tomes. In fact, the agitation which led to the granting of the Charter and the establishment of the diploma was so strong that it produced these great results in addition to the Charter. Nor were the provinces behind in this respect. The Dental Dispensary was founded in Birmingham even earlier in the year 1858 than the dental hospitals in London. Liverpool had its dental hospital in 1860, and, where Liverpool stepped, you may be sure Manchester was not far behind. There was another foundation during that period. The Odontological Society was scarcely established when its members began to collect the material for a museum. I cannot associate any name or names with the museum at its origin, but I feel sure that no one here will feel aggrieved if I attach the name of one of our guests to the later development of the collection. I believe all those who know will admit that Mr. J. F. Colyer has had as much as, perhaps more than, any other person to do with making the collection one of the finest, if not the very finest, collections which the world can show. As you all know, it used to be lodged in the rooms of the Royal Society of Medicine in Hanover-square, but it was very little used there, not nearly so much as it deserved.

I need not enter into the history of the negotiations which culminated in its transference to our care on terms of a like kind to those on which we hold the Hunterian Museum. It suffices to say that we have gladly accepted the responsibility of guarding the collection, and that we have prepared for it a large room in the basement. and directly to it. I hope you will presently visit the odontological collection, for, although it is not yet ready for study, the energy of our conservator, Dr. Keith, and the attention of our secretary, Mr. Forrest Cowell, have made it ready for your inspection to-night. The access to the staircase is through the doorway behind the statue of John Hunter, and I would have you pay attention to the statue as you pass it by. The members of the Odontological Society have every cause to be interested in it, for, just fifty years ago, a number of the members of that society clubbed together, and sent a cheque to Mr. South for £50 towards the erection of the statue. All the matters I have referred to are of interest, but they did not quite satisfy my mind. I wanted to know whether any change had taken place in the science of dentistry itself. 50 years ago the advocates of independence based their policy on what they believed to be the actual position of dentistry. "We are clearly, by policy and by practice, a body distinct from Medicine. We are kindred to it, but not of it." So said the Dental Review (i. 20, 1859); and the same year the Medical Times and Gazette wrote (December, 1859): "That dentists may possibly be better for a surgical examination we do not possibly be better for a surgical examination we do not deny; but dentistry is essentially a mechanical art, with which surgeons are not conversant." In order to see whether such views still hold good I made some study of the earlier and later volumes of the Odontological Transactions and found that, although some of the earlier volumes contained papers of wide interest in connexion with the teeth, these were for the most past the work

of surgeons, that the later volumes contain many more communications of this kind, and that they are for the most part furnished by dental surgeons.

[Mr. Butlin proceeded to review the purpose and scope of modern dental literature, showing how it includes an increasing amount of general medical and surgical knowledge having special application to odontology and stomatology. He continued:

From the point of view of an outsider, the teeth seem to me as important in their relation to the health of the individual and of the community as the eye and ear. The early decay of the teeth and the conditions on which it depends in these degenerate times are matters of national importance. The presence of a dental surgeon is of more value to an army in the field than the presence of almost any other specialist. (Mr. Arnold Rogers, F.R.C.S., in his Presidential Address before the Odontological Society in February, 1859, said: "He believed, further, that the day is close at hand when dental surgeons will be brought into requisition in the army, or else that men specially qualified to treat dental diseases will be appointed to battalions." There had already appeared an article in the British Journal of Dental Science, iii., 46, in favour of this course, but "the question naturally arises, where can we obtain a staff of competent dentists, if called for?" &c. In those days the soldier had still "to bite the cartridge.") In truth, a great change has come over dentistry. It is no longer "the mechanical art of dentistry"; it is the art and science of odontology. And this change has been effected in the course of 50 years, by two generations of men. Seeing this change, I asked myself, What are they going to do with it? And I ask you, Gentlemen, What are you going to do with it? You have made odontology one of the great specialties of medicine, and yet the most of you stand outside medicine; in such a manner that I cannot help perceiving that the present position of odontology is a standing menace to medicine, for it presents the remarkable spectacle of a large number of men practising a specialty in medicine who are not qualified in medicine. I speak advisedly when I use these words. And I will give you a reason for them. During the last year in which I was Dean of the Faculty of Medicine of the University of London a proposition was brought before the Faculty to establish degrees in dentistry. It came, as I think, from the Board of Dentistry, and was presented in two forms—the establishment of degrees which should only be given to the holders of M.B., B.S., and of a degree of Bachelor of Dentistry to be given to persons who had not qualified in medicine. I presided over the meeting of the Faculty at which the question was discussed. The second proposition was supported by the surgeons rather than by the dentists, and was attacked by the dental members of the Faculty. The proposition to establish degrees in dentistry was rejected by 16 votes to 13. Shortly afterwards I became a member of the Senate of the University, and I had not been there long before this proposal to establish degrees in dentistry was sent up to the Senate, recommended by the Academic Council. It was nearly passed through the Senate. but was deferred on my motion. Later, it was referred to the Committee of Medical Members of the Senate. If my memory serves me true, nine of us were present at that meeting of the committee. Eight of the nine voted in favour of the degrees, and my vote alone prevented a unanimous recommendation to the Senate. Before the question again came before the Senate I had gained to my view two or three of the medical members, and had been supported by the opinion of some of the leading practitioners of odontology in London. So that when the final discussion took place in the Senate it ended in a resolu-tion, moved by Sir William Collins and seconded by Mr. Butlin, "That the next business be proceeded with." even more shocked at the arguments which were brought forward in favour of establishing university degrees of an inferior class than I was by the proposal itself. Some of them were weak, others of them were wicked.

No, Gentlemen, I am afraid the present position of odontology can only be justified on one of two grounds: that every young man who wishes to practise one of the "ologies' should be permitted to do so without qualifying in medicine and surgery; or -- but I am sure you will not accept thisthat odontology stands on an inferior plane to all the other

one nor the other of these two alternatives, I would suggest in the interest of odontology, in the interest of medicine in its widest sense, and, last but not least, in your own interest, that you should do all that lies in your power to take the next great step forward, and place your specialty on the same lines as, and in equal position to, the other great specialties of medicine.

Mr. Butlin concluded by giving the toast of "The Dental Profession," to which Mr. Hern and Mr. Brooks responded.

Mr. HERN, in replying to the toast of "The Dental Profession," said that he had no doubt been called upon to reply to this toast because the Odontological Section of the Royal Society of Medicine, of which he had the honour to be President, had played such an important part in those early days referred to by the President, when all those efforts were made to bring the dental profession into a solid phalanx. 50 years ago there was no cohesion, no pro-fessional brotherhood, and until the middle of the last century no step had been taken towards cohesion. The 18 memorialists to the College had taken the initiative in that direction, and these early pioneers must be looked upon as being the founders of the dental profession, as well as of the Odontological Society. He referred to the value in the eyes of the public of a qualification granted by such a body as the Royal College of Surgeons rather than that granted by an independent body, but thought that the opponents of the scheme of the Odontological Society and the Royal College of Surgeons had been equally successful in raising the professional status of the dental profession. To his mind the benefits accruing from the institution of the L.D.S. diploma were many: it enhanced the status of the profession, it also increased public confidence, and engendered a feeling of professional brotherhood. When the Royal Society of Medicine in 1907 was in process of formation and the various scientific bodies were being merged, the licentiates in dentistry were considered to have a qualification of their own and were considered not less worthy than other practitioners for entrance to Membership and Fellowship of that body. Dental surgery was then acknowledged as an important branch of the healing art. In conclusion, he paid a tribute to the arrangers of the odontological collection in the Museum, and thanked the College for their hospitality.

Mr. Brooks, in tendering thanks for the kind way in which the toast had been proposed, said that whilst he did not pretend to agree with all that had been said by the President, he was none the less aware of the great benefits which the granting of the charter and the institution of the licence had conferred, and was also sensible of the very distinguished honour which he shared with Mr. Hern in being called upon to speak for the dental profession at so momentous a period in its history as the "jubilee" of the granting of that charter, or as he would express it "the grafting of dentistry upon an advanced stem of surgery." He felt that as time went on and science progressed the dental profession must become more closely allied, or as the President suggested, an integral part of the whole profession of medicine, seeing that their history, training, achievements, and their aims were so closely interwoven. The association which he had the honour to represent was united, in fact absolutely united, upon their fundamental objects-viz., the common good of dentistry and of humanity. With regard to the progress of their science, it had made remarkable advances, and now the State was beginning to realise that there is a national work to do. But perhaps the most significant point of all was the evolution of the ethical idea among practitioners themselves, who had learnt that union meant strength. They would be justified in looking forward to the future with some amount of confidence, and in face of difficulties which had yet to be surmounted he had no fear as to the issue, seeing that the dental profession had the support and sympathy of

the Royal College of Surgeons.

Mr. Tomes, in proposing the toast of "The Royal College of Surgeons of England," said that in order to realise the debt which the dental profession owed to the College of Surgeons it was worth while to consider the state in which the dental profession was at the time before the memorial was sent up to that body, and referred to the part played by his father in the early days before qualification was an essential to practise dentistry. great "ologies" of medicine. If you will have neither the He recalled the fact that it was his father who sketched out the curriculum for dentistry which was adopted by the College, and the foresight which he then showed was evidenced by the fact that it had lasted with the exception of a few minor alterations until the present day and had been adopted by every licensing body in the kingdom. He said that he hoped the idea of autonomy for the dental profession would not arise in the future. He considered it a happy thing that the President of the College (with whom he coupled the toast) should at this moment be Mr. Butlin, on account of his being identified very largely with work on the more serious aspects of oral diseases.

After Mr. BUTLIN had briefly replied, an adjournment was made to the Museum where the odontological collection was inspected and deservedly admired.

SOME CONSIDERATIONS OF MEDICAL EDUCATION.

VII.1

Intricacy of Educational Problems.—One Portal System.— Extension of the Statutory Time of the Curriculum.

RETURNING from consideration of the peculiar position of the London students to the main theme, we see that the difficulties in the medical curriculum have long been recognised by the General Medical Council and by all who have had their attention drawn to the matter through practical interest in the education of the medical student. The brief accounts which have been given of the various proposals for making the educational course of the student practical as well as sufficient for the public needs can hardly have failed to show any who have read them the grave problems which lie ahead, and their intricacy, together with the magnitude of the interests involved, form a sufficient apology for not putting forward any comprehensive scheme for the general reform of a system in which there is so much that is excellent, in which so many of the apparent drawbacks can be actually interpreted as virtues, and in which every situation is shifting and tends to shift more with the general progress of our science. it will be of service to consider the course along which valuable differences might be made in the existing procedure, under the idea that with the disappearance of some admitted evils the formation of a scheme of a comprehensive nature should become possible in the future.

Here we arrive at an inevitable point—the question of the merits of a one-portal system and the probabilities of such a system, with its implied State degree in medicine, ever being instituted. These are matters which have been much discussed in THE LANCET, and in bringing them again to the front it is with the admission that there is nothing new to be said about them, and with the feeling that brevity will be excusable. But only a week ago this scheme was advocated in our columns in a letter from a well-known London consultant surgeon. The "one-portal" system has been desired ardently by most liberal thinkers as doing away with the opportunities that some students may enjoy of entering the medical profession upon easier terms than their fellows. The simple way of securing the one-portal system would be for the State to hold identical examinations in certain capitals and university towns simultaneously and to admit the successful candidates to the Medical Register under the title of M.D., or at least with the clear specification that each man admitted could call himself "Doctor." As far as the public would be concerned all medical men would then be equal, and any favour which a man enjoyed with the public would be due to his work and his character. Appointments would no longer be open only to graduates of certain universities or diplomates of surgery of certain corporations, but of course all honour qualifications would continue to facilitate election for their possessors. Every candidate for a post would then produce, as additional evidence of fitness, any testamurs that

he possessed, but the non-possession of them ought to bar no man from competing, for all men on the Register would be on the Register for the same reason—the State qualification. The London student, whose anomalous position has been considered, working in the splendid clinical field of the metropolitan hospitals with the elaborate scientific environment of a metropolitan medical school, when entering private practice would no longer find himself at a disadvantage, even though he did not avail himself of the University of London. All medical men would be equal in the eye of the public, and the substantial grievance under the present régime, that of two equally well-informed men one has and the other has not an academic right to the popular title of "Doctor, would disappear. But this simple way of making medical education uniform and of avoiding a multiplicity of examinations would probably be opposed by the medical corporations, if not by the universities, and in that case have little chance of becoming law. who preside over the corporations are aware of the difficulties ahead of them owing to the creation of new universities having the power of granting medical degrees, but the corporations have by no means exhausted their educational functions—the vast majority of the medical profession enter that profession through their portals or take their qualifications in addition to their medical degree—and such bodies are not likely to acquiesce in a system which might greatly damage their utility and prestige. governing bodies of the corporations cannot fail to see that their policy in the face of this creation of new universities is to join hands with these and the older universities, as far as they can do so without sacrifice of dignity or breach of trust in respect of their constitutions. In this way the corporations would help the medical faculties of the universities. and the universities would help the diplomates of the corporations, while considerable economy of effort and money ought to be effected by such fusions of interests. possible establishment of relations between the University of London and the English corporations becomes, it will be seen, a matter of vital importance in medical education.

However much we may regret the disappearance of an ideal deeply cherished by some of the soundest medical reformers the scheme of a State degree seems out of the range of practical politics, and we must look elsewhere for a method of dealing comprehensively with admitted defaults.

Two things are certain. If it is granted that the medical student has now more to learn in the time allotted to him than he can master (and this fact is one of the arguments upon which the one-portal system with its simplification of examinations has been based), either this overloaded curriculum must be better defined so that the student shall waste no time and shall not be exposed to great chances of rejection at the hands of a multiplicity of examiners, or the duration of the medical curriculum must be prolonged. In the brief but detailed account which has been given of the many recent debates at the meetings of the Council, having their origin in the discussion of this question or points germane to it, it appears to be admitted on all hands that the curriculum is overloaded, which indeed seems sufficiently proved by the fact that although by statute its duration is five years in practice the average time taken by the student is considerably over six years.

Considering firstly the extension of the curriculum, the tendency towards change in this direction is sufficiently indicated by two things, both of which have been alluded to in these articles. The University of London has definitely extended the statutory time from five years to five and a half which its graduates of medicine must take to obtain degrees. The other point is that the Conjoint Board of the Royal College of Physicians of London and the Royal College of Surgeons of England, which used to count a year's work in the preliminary sciences done at a recognised secondary school as counting for a year's time in the five years curriculum, will now only allow six months for such work to schoolboy students. The action of the University of London is not very likely to be imitated, or at any rate cannot be counted as any promise that all the educational bodies will take the grave step of lengthening the medical curriculum to any appreciable extent, but the departure is significant. It shows the University to be desirous not to make its degrees easier of attainment, while it supports the fact that the curriculum is overloaded. If any general movement in other Universities in imitation of the University of London is expected, it must not be forgotten

¹ Nos. I., II., III., IV., V., and VI. were published in THE LANCET of Oct. 23rd (p. 1232) and 30th (p. 1301), Nov. 13th (p. 1459), 20th (p. 1531), and 27th (p. 1616), and Dec. 4th (p. 1694), 1909, respectively.

that medical students are not recruited on the whole from a wealthy class of the community, while their period of student life is necessarily passed in the large centres where the price of living, given all economy, is none the less high. Nor must it be forgotten that a large proportion of medical men do not make big incomes, so that the compulsory addition of any period whatsoever to the time of studentship is demanding from the student an additional premium for entrance into a profession which does not hold out for him any additional prizes as compensation. And, lastly, the medical education of this country is extremely ill supported by funds, and it is unfair to add to the burdens of those who now carry on this education almost gratuitously. It is understood that a movement has been made in one place with success to secure recognition of a medical school as a technical school with a right to a Government grant. If this principle became common those responsible for the education of medical students might recognise with more complacency an extension of the curriculum. Although the easiest way of all out of the difficulties with which the Education Committee of the General Medical Council is now dealing would be to lengthen the statutory time of the student's course, and although apparently only 13.8 per cent. of the students actually complete their studies within that time, the Council is not likely to insist for the present upon the student's curriculum being longer than five years. The highly interesting debate, which is reported on p. 1750, confirms this view, though the developments of the future may make a difference in the opinion of the Council.

(To be continued.)

THE REPORT ON SCOTLAND OF THE ROYAL COMMISSION ON THE POOR-LAWS AND RELIEF OF DISTRESS.

11.1

THE subject of Poor-law medical relief in Scotland was investigated in 1904 by a departmental committee of the Local Government Board, presided over by Mr. J. Patten MacDougall, C.B. (a member of the recent Commission), and the report of the latter refers its readers to that of the committee for details of the system. The only statutory enactments with regard to Poor-law medical relief in Scotland are to be found in the Poor-law Amendment (Scotland) Act, 1845, by which it is enacted that medical officers must be appointed to poorhouses, to give regular attendance and to be paid a reasonable remuneration therefor, and that out-door medical relief is to be provided "in such manner and to such extent as may seem expedient." This enables a parish council to engage for outdoor relief a medical officer at a salary or to employ a medical practitioner as the occasion arises and to pay him a fee for the service rendered The "Board of Supervision," constituted as a central authority in Poor-law matters in Scotland in 1845, and superseded in its functions by the Local Government Board of Scotland so recently as 1894, was without representation in Parliament and was not liberally endowed with powers over the administration of relief. It was able, however, to obtain from Parliament in 1848, in order to assist in the promotion of an outdoor medical service, an annual grant of £10,000. This grant was increased in 1882 to £20,000, and in 1885, in order to encourage the introduction of trained nursing into poorhouses, the cost of such nursing was made a first charge against it. The medical relief grant was converted into a powerful agency for the improvement of Poor-law medical relief by two conditions attached to participation in it—namely, that there should be a fixed minimum expenditure on medical relief by each parish, to which a grant was made, and that a medical officer should be appointed. It also caused the establishment of a system of trained nursing in poorhouse infirmaries. The above conditions, which originally were beneficial when they were embodied in regulations made by the Board of Supervision, have since been stereotyped by incorporation in the Local Government (Scotland) Act. 1889; and as their relaxation to suit particular cases is often desirable, the amendment of Section 22 of the above Act was advised by the Medical

Relief Committee, whose recommendation is now endorsed by the Commission, the suggestion being that the Local Government Board should be enabled to make rules which would be of a more elastic character. The increase of the medical relief grant is recommended as an alternative for the introduction of the system known as "block grants. Under present conditions, as indicated above, parish councils have a very free hand in the matter of medical outdoor relief, and although the approval of rules for the dispensing and supplying of medicines in poorhouses is one of the powers of the Local Government Board, the Medical Relief Committee found that no such rules had ever been submitted to the Board. As to this, the Commission recommends the giving of powers of initiative to the Board, and advises "that the Local Government Board should be empowered to prescribe from time to time the arrangements necessary for providing the poor with medical assistance and nursing; and that the arrangements for indoor and outdoor medical relief should be periodically inspected on behalf of the Board by a medical inspector.

Indoor Medical Relief.

In the matter of indoor medical relief the Commission finds considerable cause for comment in Scotland. Glasgow only there are Poor-law hospitals erected on sites detached from the general poorhouse. "The great advance in this respect, which dates in England from 1867, can scarcely be said to have begun in Scotland." In other parishes there are well-equipped hospitals or wards suffering, in the Commission's opinion, from their direct connexion with the poorhouse; in others, again, the accommodation is worse; and in some there are no sick wards at all, healthy and sick inmates being mixed up together.

The Commissioners quote from the report of the Medical Relief Committee the statement that the medical officer of the Scottish poorhouse, who appears to be frequently nonresident, does not enjoy the position to which he is entitled, and, as an example, has no voice in the selection, suspension, or dismissal of nurses. The insufficiency of the medical staff when kept, as it often is, at its minimum numerical strength, is condemned.2 Great deficiency is found to exist in the provision of trained nursing in spite of the improvement effected through the agency of the grant. The Commissioners report that they "regret to find that out of 68 poorhouses in Scotland there are still 26 that have no trained nurses. Not only so, but pauper nursing, it appears, is permissible in all Scottish poorhouses." The following conclusions with regard to these conditions are followed by recommendations calculated to provide for their amelioration:

tions calculated to provide for their amelioration:

That, in spite of recent improvements, the provision made by Poorlaw authorities for the treatment of the sick indoor poor is inadequate because the accommodation is in many cases defective; that the sick are not properly classified; that the position of the poorhouse medical officers is administratively anomalous; that in some poorhouses the medical staff is insufficient; that the salaries of the medical officers call for revision; that the nursing staff is in many cases insufficient; and that pauper nursing should be abolished.

That much good would accrue if poorhouse hospitals were opened for purposes of clinical instruction. That there is an increasing demand on the part of the general population for hospital treatment in sickness; that the voluntary hospitals are unable to cope with the demand; that further hospital accommodation is necessary in different parts of the country; that the benefits of the hospitals are frequently abused by the well-to-do; that the Poor-law authorities are gradually being forced to provide accommodation for cases that formerly would have been treated in a voluntary hospital; and that there is overlapping and want of cooperation between the voluntary hospital and Poor-law authorities. want of co

The Commission as to these latter conditions recommends: That the sick poor should be accommodated in hospitals on sites detached from the poorhouses, adequately staffed, under the super-intendence of a medical officer, and open for the purposes of clinical

It recommends also the conversion of superfluous poorhouses into hospitals, and that arrangements should be made where necessary for the reception of patients in voluntary and general hospitals, subject to payment made on their behalf by the authorities responsible for them. It also advises the desirability of compulsory powers of removal and detention of patients being given to Public Assistance authorities and parish councils.

Outdoor Medical Relief.

Outdoor medical relief is largely due in Scotland to the operation of the medical relief grant which has secured the appointment of a medical officer or officers at a fixed salary in 800 out of the 874 parishes in Scotland. In towns it is

¹ The first article was published in The Lancer of Dec. 4th, p. 1698.

² Fuller particulars as to this, with special reference to Edinburgh are given in the Minority Report, pp. 260, 261.

largely supplemented by medical charities and by the private benevolence of medical practitioners who give gratuitous attendance, and in these circumstances it is found by the Commission to be chiefly defective through want of practical cooperation between the various organisations. towns and in the Lowland districts the Commission has received no evidence to show that outdoor medical relief is generally inadequate, but the opinion is expressed that the provision of it by the Poor-law may be largely supplemented by the gratuitous attendance of private practitioners. "But (the report continues) as regards the Highlands and islands, it is clear that the medical attendance in many parishes is deplorably insufficient, and affects not only the physical well-being of the paupers but also that of the whole population. At the same time it appears that, notwithstanding the deficiency, the paupers themselves are better off in respect of medical attendance than the class immediately above them. The problem in these parishes is to secure even a minimum of medical attendance for the inhabitants.

The following will illustrate this point. The Island of Lewis has been mentioned already. On its western side is a district with a population of 13,000, scattered in about 40 villages. It is 72 miles long by the only existing road, and villages not situated upon the road must be visited on foot. All the medical attendance available has to be given by two medical men living 50 miles apart. In four parishes of Inverness-shire, as recorded in 1900, there were respectively 70, 67, 64, and 51 per cent. of uncertified deaths, and lest percentages should be deemed to be misleading we are given in respect of others the following figures:—

		To	Total dea		Uncertified.
	Lewis Mid Ross Western Ross		390		114
Ross-shire	Mid Ross		204		57
	Western Ross		81		43
	Harris		67		34
	Shetland (landway	d)	337		114

Trained nursing as a department of outdoor poor-relief in Scotland does not appear to exist. There is no grant available for it, and it is not provided for directly either in the Poor-law Act, 1845, or in the medical relief rules. district nursing associations, however, and notably Queen Victoria's Jubilee Institute, do good work, the latter agency being represented by 248 nurses in different parts of The evidence of medical witnesses is cited by the Commission to show how great is the need for adequate nursing by women capable of undertaking it under the conditions in which it would have to be done, and according to these gentlemen it is nurses to work under their directions rather than a large supply of medical practitioners that is needed. The Commission calls attention to the deplorable conditions in respect of sanitation which prevail in the homes of the population in many districts. In discussing outdoor medical aid rendered by agencies other than the Poor-law, the Commissioners assign a prominent place to the gratuitous service rendered by medical men, and find that in large towns there are many medical charities. These, they consider, are abused in many instances by persons able to pay for treatment, and they comment on the fact that in spite of the supposed thriftiness of the Scotch there should be no provident dispensaries or public medical service on a provident basis.

With reference to phthisis, the Commission finds the Poor-law authorities to be alive to their duties but hampered in the performance of them by circumstances. In most poorhouses phthisical patients are segregated, but the objection entertained by the poor to entering the poorhouse militates against success, and as an instance of the anomalies brought about by the existing law it is mentioned that though the healthy dependents of a phthisical patient received into a poorhouse are given outdoor relief as a rule, the phthisical dependents of an able-bodied man cannot be received into the poorhouse at all. A certain amount of boarding out in private dwellings in country places and in sanatoriums takes place.

The Commission makes proposals for the amelioration of the conditions under which medical officers perform their duties; for the drawing up of a scale of fees for special operations and for midwifery cases; for the defraying of the cost of drugs otherwise than out of the pocket of the medical officer, and for the providing of housing accommodation for him where it is needed; for the appointment of additional medical officers; and for the provision of trained nursing for

outside patients. They recommend that no disfranchisement should be attached to any form of medical assistance and that the administration of the Vaccination Acts should be handed over to the sanitary authorities.

In considering the question of the great need for medical aid among the poorer classes generally—i.e., including those not otherwise in need of public assistance—the Commission

1. A better supply of hospital accommodation should be provided based upon the needs of each Public Assistance area.

based upon the needs of each Public Assistance area.

2. That a united effort should be made to prevent the abuse of medical charities by persons in a position to pay for treatment.

3. That there should be systematic cooperation between the Public Assistance Authorities, the sanitary authorities, the education authorities, and the voluntary medical institutions, based on a clear definition of their respective functions.

tion of their respective functions.

4. That a joint committee representative of these authorities and of the medical profession should be appointed for the purpose (a) of framing sohemes of cooperation to be adopted by the various bodies concerned; and (b) of considering after consultation with the Voluntary Aid Council, where such exists, the needs of each Public Assistance area in regard to hospital accommodation. That steps should be taken to organise, with the cooperation of the medical profession, a system of medical aid by some form of insurance—e.g., by the establishment of provident dispensaries or medical clubs; and that a departmental committee should be appointed to consider the means by which such a system can best be organised.

The remaining parts of the Committee.

The remaining parts of the Commission's report deal withthe Poor-law"; VII., "Miscellaneous Questions," which include the recovery of the cost of relief; settlement and removal; rating; vagrants; and the detention or continuous treatment of certain classes of cases receiving or applying for public assistance. With regard to Part VI., the overlapping and want of coordination in the distribution of a very large volume of charitable assistance is dwelt upon, and the formation of voluntary aid councils and committees for the remedying of abuses and insuring effective aid being given in suitable cases is recommended. The persons referred to in Part VII. include the feeble-minded, with regard to whom it is recommended that they should be subject to complete control on the lines laid down by the Royal Commission on the Care and Control of the Feebleminded.

We have given above a sketch of the principal matters of interest to the medical profession dealt with by the Majority Report of the Royal Commission. We have spoken of it as the report of the Commission, which, indeed, it is, and we recommend those in need of fuller information to refer to its pages, for they contain a very great deal that is of considerside with the report on England and Wales the report on the Scottish Poor-law shows the marked differences which, partly due to geographical and climatic causes, exist between two races united under one government and inhabiting adjoining territories. Like the report on England and Wales, it raises the hope that steps may be taken without delay to remedy the more readily remediable evils revealed and to initiate a new and better order of things in the matter of "public assistance.

To the Majority Report there is added, as in the cases of England and Wales and of Ireland, a Minority Report signed by the same dissentient four members of the Commission. It also contains a great deal that is interest-ing and well worthy of study, and the two reports read together form, as in the case of England and Wales (rather than that of Ireland), a most important treatise upon the subject dealt with. The Minority Report relating to Scotland makes the same recommendations that were put forward upon the two previous occasions for dividing up the subjects of public assistance between local authoritiesalready constituted and for assigning control and recovery of costs to a registrar. Lord George Hamilton, the chairman of the Commission, adds a reply to the Minority Report and (subject to our expressed opinion that the Minority Report contains important and interesting matter) we are inclined to believe that the criticism contained in his memorandum is not altogether unjustifiable. In his first paragraph he observes, with regard to the Minority Report, that the latter part of it is not a report upon Scotland or dealing with the peculiarities of the system in force in that country, but is an enlarged and varied edition of their original proposals intermingled with a new set of comments and criticisms upon the proposals of the Majority."

A memorandum by Professor Smart on the history of the Scots Poor-laws prior to 1845, published as an appendix, will be found well worthy of study.

MOTORING NOTES.

BY C. T. W. HIRSCH, M.R.C.S. ENG., L.R.C.P. LOND.

The Question of Light and Inexpensive Cars.

AT one time it was the policy of motor-car builders chiefly to cater for those to whom money was of little moment and who were indifferent not only to initial but also to running costs. Now nearly all the makers are turning their thoughts to the motorist of moderate means, and in this category the majority of the profession may, I think, be counted. Unfortunately the general tendency seems to be in the direction of the so-called light four-cylinder car. I am not disparaging, nor do I wish to disparage, this type, but for many of the chauffeurless doctors even a lighter runabout would be more useful. The lighter the car the lower the horse power, and thus less consumption of fuel and tyres. Lightness is an important factor in the matter of production and running expense; increase in dead weight not only means increase in the horse power needed to push the car along but also decrease in the real strength of the car, for the strains to which a car is subjected depend on the propelling force and the resistance of the road, and these increase in the actual ratio of the weight, and with this increase comes increased strain. It is therefore certain that the two points which the medical man, who intends to become a motorist. should consider when thinking of a car are lightness and simplicity; both spell absence of trouble—the former low

tyres, small fuel, and upkeep bills, and the latter the absence of repair accounts; in fact, on a simple car the owner should be able to do most of the repairs himself.

The General Construction of a Simple Car.

The chassis—
that is, the car

wheels, and some method by which in passing this power can be increased when more work is required of the car, as in climbing a hill. This is usually carried out by what is known as the Panhard type of change speed, and consists of a gearbox containing two shafts. One is connected by the clutch with the crank shaft of the engine, and on this spindle-toothed wheels slide. It is usually made in two parts, the end of one having a bearing in the end of the other, and by means of a dog clutch the two parts are made one and revolve together, and then the engine power is directly carried to the bevel at the end of this shaft, or rather at the termination of the cardan shaft, to which this shaft is connected, and thus to the differential and road wheels. is the direct drive; otherwise the power is transmitted by a pinion to a second or lay shaft, and then back to the second half of the first shaft by toothed wheels, which can be slid in and out of gear, and in this manner also to the differential The accompanying diagram illustrates a usual and wheels. type of gearbox. By means of a third pinion on a separate shaft, through which the first shaft drives to the second, the reverse is obtained. The differential gear is a set of wheels arranged so as to average the speeds of the two driving road wheels when the car turns a corner, and this balance mechanism, by means of satellite pinions, distributes the power automatically between the two wheels, so that the outer one can travel faster than the inner one.

In addition to these parts the chassis consists of a frame on which these members are fixed, of springs to which the carriage body is attached, steering gear, axles, road wheels.

The engine in its most elementary form is a casting in which a piston can work up and down, and of course the inside of the engine casting or cylinder is machined, so that the piston is a perfect fit. By means of a valve the vapour of petrol, from a vaporiser or carburettor, is admitted to the cylinder; the piston ascends and compresses this mixture; at the correct moment, by means of the commutator attached to the two-to-one shaft, an electric current circuit is completed, there is a spark in the cylinder, the mixture explodes and forces down the piston, and the force of this thrust-down of the piston is transmitted by the piston connecting rod to the crank shaft, which is kept revolving by the flywheel, and the crank shaft through the clutch transmits the power to the gearbox and so on to the road wheels. The momentum keeps the crank revolving, and the piston ascends once more, compresses the gases left after the explosion; another valve, the exhaust valve, opens and these gases are pushed out, thus making room for fresh ones to enter, when the piston next descends and creates a vacuum. Some inlet valves are automatic-that is, they are kept shut by a weak spring and are opened by the suction action of the piston; others are, like the exhaust valve, mechanically opened—that is, they are lifted off their seats by their spindles being pushed up by tappets, which in their turn are raised by cams or eccentrics on the two-to-one shaft, which is connected to the crank by toothed wheels, with such a proportion of teeth on each that the cam shaft rotates once while the crank shaft turns round twice. This series of operations, suction (admission of gas), compression, explosion, and, lastly, expulsion of products of explosion constitute

what is called the "Otto" cycle.

Of course, great heat is produced by the explosion, and in order to allow of lubrication of the cylinder wall and piston the cylinder has to be kept cool; this is done by surrounding cylinder with a through jacket, which water is circulated by syphon or by means of a pump, and so that the water will not quickly boil away, in its course it is made to pass through

copper tubes exposed to the air. These tubes form what is termed the radiator, and on most cars the water is further cooled by a fan rapidly revolving behind the radiator, and so sucking in cool air to further the reduction of the water temperature. The ignition or explosion of the mixture is brought about by a spark, between two metal points in the cylinder, and it is this part of a car that accounts, or rather used to account, for most breakdowns and road stoppages. The latest type is the magneto, and the high tension variety seems the most satisfactory; for single cylinders it is run at cam shaft speed for four cylinders at the speed of the engine. In these instruments currents are produced by the rapid passage of coils of copper wire wound round soft iron cores between the poles of a magnet. But the objection is that occasionally magneto-fired engines need three or four turns of the starting handle before they are set in action. With the accumulator and coil system, one pole of the accumulator is connected to the primary coil, the other to the brush of the commutator; as the engine revolves this completes the circuit, an electric current passes through the primary coil, the trembler vibrates, a high intensity current is generated in the secondary coil, jumps at the sparking plug points in the cylinder, and so the mixture is exploded. With non-trembler coils there is a positive make and break at the commutator and the contact blade acts as a trembler. The usual carburettor is of the atomiser kind; petrol supplied by gravity enters a float chamber, and on the float rests an arrangement of levers, so that they work a needle valve, which cuts off the petrol when it exceeds a

certain height in the chamber; the petrol is drawn by the suction of the engine through a narrow pipe up a fine jet into the mixing compartment, air at the same time is drawn in along a tube which opens near the exhaust, so the air comes in heated, it mixes with the petrol, and the explosive mixture that results enters the engine through the inlet valve. A contrivance is fitted by which the amount of air can be varied, either by a lever or by the speed of the engine itself.

The reader with mechanical knowledge should be able to follow from this brief summary the general construction of a simple car.

Looking Back.

FROM

THE LANCET, SATURDAY, Dec. 10th, 1831.

The practice of injecting the veins in desperate cases with substances of still more energetic properties than those which the chlorate of potash possesses, is by no means new to medicine. In an extensive and brilliant series of experiments performed on horses at the veterinary school of Alfort, Dupuy demonstrated the extraordinary success attendant on this practice, and the safety with which carbonate of ammonia and many other substances could be injected into the venous system. Again, the records of toxicology afford us examples by no means unique, of the successful injection of tartar emetic into the blood in cases of hopeless narcotic poisoning. In the Journal des Progrès, vol. 3, 1830, MM. Percy and Laurent relate the cases of three Russian soldiers cured of tetanus by injections of opium into the veins. In the same journal, the same writers also mention other cases of tetanus successfully treated by the injection of a decoction of the datura stramonium in half an ounce of water.

I trust I have now said enough to induce and justify the trial of this new proposal, at least in the fearful cases in which venesection is found impossible, and the violence of the malady devides all other means of medication. Should the method be found to succeed, it will have the advantage of fulfilling all the objects which Messrs. Bell, Kennedy, and Annesley, hold in view when they practise venesection, and that without threatening to induce the debility which the detraction of blood is thought by many to endanger.

In the performance of the operation, the circumstances of the disease must be borne in recollection. When the current of the circulation is impeded, as in the blue cholera, injection from the bend of the elbow can scarcely be efficient. I would, therefore, suggest that the tube, which should be of gold or ivory, be introduced into the external jugular vein immediately as it crosses the sterno-mastoid muscle. I would select this place as the nearest spot to the superior cara, free from the danger of the entrance of air caused by the suction force of the right side of the heart, an influence which Berard has shown to be ineffective in the introduction of air, except where the flaccid orifices of a divided vein are kept gaping and stretched by adhesions to adjacent prolongations of fascia or condensed cellular substance; as is remarkably the case with the subclavian and with the jugular in the lower third of its progress. The syringe used in the injection should contain no more than three ounces, the solvent should be distilled water heated to a blood warmth, and the syringe also equally warmed. The tube should not be more than an inch long, and curved gently for the convenience of manipulation, and it should have a marked conical form. forming the operation, after the vein is exposed, I would make a puncture with a lancet, just sufficient to permit the introduction of the tube, but I would by no means detach the vessel from its connexions. The injection should be deliberately and slowly performed. From ten to thirty grains of the chlorate might, I think, be safely employed. It would, however, be essentially necessary that before the experiment was tried, a minute analysis of cholera blood should be performed, and the effects of the oxygenated salts examined, as to the change of colour and their influence on the affinity of that blood for oxygen in its uncombined or its nascent forms. To my mind no satisfactory analysis of the blood in cholera has yet been completed. HERMAN'S, the most recent and

most minute, is still, I am prepared to prove, far from deserving implicit confidence.*

* Herman mentions irec accite acid as an ingredient in healthy blood. He also states that after coagulation of the cholera blood, the crassamentum was acid and the serum alkaline! It is unnecessary to dwell on the latter statement, as it involves an impossibility. Concerning the first, it is sufficient to observe that in the best analysis of the blood ever performed—viz., that by M. Lecanu of Paris, and for which he obtained the gold medal from the Academy (vide Journal de Pharmacie. September and October, 18:11), no statement occurs of the detection of acetic acid, though, had it been present, M. Lecanu's process must have revealed its existence.

Excerpt from "Proposal of a New Method of Treating the Blue Epidemic Cholera by the Injection of Highly-oxygenised Salts into the Venous System." Read before the Westminster Medical Society, Saturday, Dec. 3rd. By W. B. O'Shaughnessy, M.D.

Public Bealth.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Administrative County of Devon.—We have received from Mr. George Adkins of Exeter a copy of his first annual report as medical officer of health for the administrative county of Devon. Although his appointment dates only from November of last year, Mr. Adkins has already found time to study the annual reports for 1908 of each of the district health officers in his jurisdiction and to summarise them for the instruction of his county council. In Devonshire coordination has fortunately been secured between the services of public health and elementary education by entrusting the supervision of both to the county medical officer of health, under the additional title of school medical officer, the four district medical inspectors of schools acting under him. Very appropriately, in a preliminary report the county medical officer gives an interesting description of the physical and geological features of Devon, which is the third largest county in England. With the general arrangement of the technical portion of this present report we are favourably impressed. It has been framed throughout in conformity with the instructions of the Local Government Board, and, what is essential for comparative purposes, the tabular matter is arranged according to the model forms of that Board. Systematically planned and tersely expressed, it contains, in our view, just the kind of local information and of expert guidance required by the supreme sanitary authority of a mainly rural area like Devonshire for the discharge of its manifold duties in relation to the public health. Mr. Adkins is fortunate in having at his disposal comparative local statistics of birth and of general mortality relating to a long series of years. The birth-rate of Devon has generally been considerably below that of England and Wales, and in recent years has shown a decline of about the same amount, the rate in the rural districts having declined, if anything, somewhat faster than in the urban. The death-rate last year in the administrative county was as low as it had been in any year of the previous ten. Referring to the relatively higher general mortality in a few of the larger health resorts, the medical officer explains that this is due to the presence of many invalids who repair thither to die, whilst as regards the urban district shown by the tables to experience the highest death-rate in 1908 we learn that this is due to excessive local fatality from tuberculosis. The report devotes careful attention to the question of infant mortality, which last year was at the low rate of 88 per 1000, the lowest for the last ten years and 33 per 1000 below that of 1899. As in other parts of the kingdom, the loss of infant life in Devonshire is far higher in the town than in the country districts. Among disorders amenable to sanitary measures the seven notifiable infectious diseases give particular reason for comment in this report. For, although their aggregate mortality was lower in 1908 than in any previous year, the reported attacks by several of them were far above the average in number. Of small-pox 3 cases were imported, the patients arriving at Plymouth from South Russia and being treated at the hospital ship in the Sound. With respect to one large town, the disquieting statement is made that 50 per cent. of the children are unvaccinated. Scarlet fever was present last year in more than half of the 52 districts of the county, more than 700 cases,

with 11 deaths, having been reported. In one borough a considerable outbreak occurred in connexion with school attendance, but none of the cases were fatal. Mr. Adkins remarks that the control of scarlet fever is difficult to maintain because of its mildness of type in recent years. The disease is generally spread in recent years. through school attendance; indeed, many of the infected children, not feeling ill enough to discontinue attendance, are found in the schools desquamating, or discharging infectious matter from the nose or ears. Diphtheria was prevalent last year in 36 of the districts, more than 500 cases having been reported, 10 per cent. of which ended fatally. The worst outbreak occurred at a favourite health resort, where immunity from this disease had been enjoyed for several years. Many of the attacks were related to school attendance. In a neighbouring town, in which 65 cases occurred, the spread of infection was traced to "carrier cases" among school children. Devonshire is by no means free from enteric fever, as many as 112 cases, with 18 deaths, having been reported there last year. The disease was distributed over 25 districts. Many of the cases are believed to have been caused by contaminated shell-fish. In this case also the influence of "carrier cases" is believed by the medical officer to have been concerned in the propagation of the disease. He mentions an instance in which a woman communicated infection, having herself suffered from attack by enteric fever nine years previously. Among other conditions that are admittedly amenable to sanitary influence considerable space is devoted to the subject of tuberculosis. The pulmonary form of this disease caused 479 deaths, and other forms 142. Mr. Adkins makes some vigorous remarks concerning its prevention and its area of distribution. Of administrative action for the prevention of disease the report contains satisfactory account, but the county medical officer regrets that the district medical reports are presented in manuscript only, and he points out the advantages that would accrue to all if they were in every case available in printed form. In all rural areas the danger of pollution of drinking water is a constant source of anxiety to sanitary authorities. We read that in Devonshire the liability to pollution is much in evidence in certain districts, but that in several instances improvements are in progress. Considerable attention is devoted to the maintenance of a pure milksupply. In some districts the regulations respecting registration and other sanitary precautions are not complied with by dairymen and in others the cowsheds are filthy and the cows and milkmen are anything but clean. Serious attention to these important matters is very properly urged in the report upon the district councils. Mr. Adkins gives interesting particulars respecting the methods of dealing with infectious disease in his jurisdiction. Only 13 of the urban and 4 of the rural districts have made hospital provision for isolation. In the remaining districts the patients have either to be sent to distant hospitals or else to be isolated as well as possible at home. With the object of securing timely information of outbreaks of infectious disease the county medical officer is provided with a weekly list of such occurrences within the administrative county, and by the courtesy of the medical officers of Exeter, Plymouth, and Devonport this list is supplemented by returns for those county boroughs. In many of the districts of the county the councils have provided antitoxin serum for the treatment of diphtheria, and the general purposes committee of the county council has recently sanctioned the provision of free bacteriology for use throughout its area in dealing with infectious diseases.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 76 of the largest English towns 7056 births and 5196 deaths were registered during the week ending Dec. 4th. The annual rate of mortality in these towns, which had steadily increased in the five preceding weeks from 12.0 to 16.4 per 1000, further rose to 16.5 in the week under notice, and exceeded the rate recorded in any week since the middle of April last. During the first nine weeks of the current quarter the annual death-rate in these towns averaged 13.7 per 1000, and in London the mean rate during the same period was 13.5. The lowest annual rates of mortality recorded in the 76 towns last week were 7.7 in East Ham, 8.0 in Walthamstow, 8.4 in Hastings, and 9.1 in

Croydon; the rates in the other towns ranged upwards, however, to 23.1 in Brighton, 25.5 in Swansea, and 28.0 in Hanley and in Oldham. In London the recorded death-rate last week was equal to 16.0 per 1000. The 5196 deaths registered in the 76 towns last week showed a further increase of 29 upon the numbers returned in the five preceding weeks, and included 297 which were referred to the principal epidemic diseases, against 281 and 278 in the two preceding weeks; of these 297 deaths, 65 resulted from whoopingcough, 58 from diarrhoea, 53 from measles, 48 from diphtheria, 41 from scarlet fever, and 32 from "fever" (principally enteric), but not one from small-pox. The annual rate of mortality from these epidemic diseases last week was equal to 0.9 per 1000, corresponding with the rate in each of the two previous weeks. No death from any of these epidemic diseases was registered last week in Bradford, East Ham, Brighton, Tottenham, or in nine other smaller towns; the annual death-rates therefrom ranged upwards, however, to 2.7 in Blackburn, 2.9 in Burnley, 3.8 in Hanley, and 4.0 in South Shields. The deaths from whooping-cough in the 76 towns, which had been 69 and 61 in the two preceding weeks, rose again to 65 last week, and caused the highest annual rates, 1.1 in Oldham and 1.4 in Ipswich. The 58 deaths attributed to diarrhœa exceeded the number in the previous week by 3, and showed the greatest excess in Blackburn and South Shields. The 53 fatal cases of measles exceeded the number in any recent week, and caused annual rates equal to 1.2 in York, 2.0 in Burnley, and 2.3 in Hanley. The 48 deaths from diphtheria showed a decline of 10 from the number in the previous week; they included 9 in London and its suburban districts, 4 in Liverpool and Bootle, 3 in Manchester and in Newcastleon Tyne, and 2 each in Bristol, Hanley, Leeds, South Shields, and Gateshead. The 41 fatal cases of scarlet fever corresponded with the number in the previous week, and included 14 in London and its suburban districts, 4 in Birmingham and King's Norton. 7 in Liverpool and Bootle, and 2 in Blackburn. The 19 deaths referred to "fever" exceeded by 13 the number returned in each of the two preceding weeks; 3 occurred in Liverpool and in Manchester, and 2 each in Smethwick, Bolton, and Oldham. The number of scarlet fever patients under treatment in the Metropolitan Asylums and London Fever Hospitals, which had declined during the seven preceding weeks from 2810 to 2518, had further fallen to 2488 on Saturday last; 281 new cases of this disease were admitted to these hospitals during last week, against 308 and 264 in the two preceding weeks. The Metropolitan Asylums Hospitals contained 3 cases of small-pox on Saturday last. Of the 1484 deaths registered in London last week, 432 were referred to pneumonia and other diseases of the respiratory system, against numbers increasing from 167 to 387 in the seven preceding weeks; these 432 deaths exceeded by 10 the corrected average number in the corresponding week of the five years 1904-08. The causes of 41, or 0.8 per cent., of the deaths registered last week in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death registered last week were duly certified in Leeds, Sheffield, Bristol, West Ham, Bradford, Hull, Nottingham, Leicester, Salford, and in 44 smaller towns; the 41 uncertified causes of death in the 76 towns last week included 7 in Liverpool, 5 in Birmingham, and 3 both in Manchester and in Sunderland.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 800 births and 797 deaths were registered during the week ending Dec. 4th. The annual rate of mortality in these towns, which had steadily increased in the five preceding weeks from 12.9 to 24.2 per 1000, declined again to 22.3 in the week under notice. During the first nine weeks of the current quarter the annual death-rate in these Scotch towns averaged 16.5 per 1000, and exceeded by 2.8 the mean rate during the same period in the 76 largest English towns. The annual death-rates last week in these Scotch towns ranged from 12.0 and 13.4 in Aberdeen and Leith, to 27.3 in Glasgow and 33.9 in Perth. The 797 deaths from all causes in the eight towns last week showed a decline of 69 from the high number in the previous week, and included 88 which were referred to the principal epidemic diseases, against 66, 77, and 98 in the three preceding weeks. These 88 deaths were equal to an annual rate

of 2.5 per 1000; the mean rate from the same diseases last week in the 76 English towns did not exceed 0.9 per 1000. The 88 deaths from these diseases in the Scotch towns last week included 43 from measles, 17 from whooping-cough, 11 from diarrhoea, 9 from scarlet fever, and 4 both from diphtheria and from "fever," but not one from small-pox. The fatal cases of measles, which had been 22, 36, and 49 in the three preceding weeks, declined again to 43 last week, of which 40 were returned in Glasgow. The fatal cases of whooping-cough, which had been 12 and 9 in the two previous weeks, rose to 17 last week, of which 8 occurred in Glasgow, 3 in Edinburgh and in Dundee, and 2 in Greenock. The 11 deaths attributed to diarrhœa showed a decline of 5 from the number in the previous week, and included 4 in Glasgow, 4 in Edinburgh, and 2 in Dundee. Of the 9 fatal cases of scarlet fever. 5 occurred in Glasgow and 3 in Edinburgh; and the 4 deaths from diphtheria included 2 both in Glasgow and The 4 deaths referred to "fever," of which in Dundee. 3 were certified as enteric and 1 as cerebro-spinal meningitis, included 2 in Glasgow and 2 in Aberdeen. The deaths referred to diseases of the respiratory system in the eight towns, which had increased in the five preceding weeks from 68 to 298, declined again to 265 last week, but exceeded by 151 the number registered in the corresponding week of last year. The causes of 23, or 2 · 9 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 76 English towns the proportion of uncertified causes of death last week did not exceed 0.8 per cent.

HEALTH OF IRISH TOWNS.

In 22 town districts of Ireland, having an estimated population of 1,142,308 persons, 568 births and 441 deaths were registered during the week ending Dec. 4th. mean annual rate of mortality in these towns, which had steadily increased in the six preceding weeks from 14.8 to 21.0 per 1000, declined again to 20.0 in the week under notice. During the first nine weeks of the current quarter the annual death-rate in these Irish towns averaged 17.7 per 1000, whereas the mean death-rate during the same period did not exceed 13.7 in the 76 largest English towns, and 16.5 in the eight principal Scotch towns. The annual death-rate last week was equal to 22·1 in Dublin, 19·8 in Belfast, 25·3 in Cork, 23·0 in Londonderry, 13·7 in Limerick, and 19.5 in Waterford; the mean rate last week in the 16 smallest of the Irish town districts was equal to 18.2 per 1000. The 441 deaths from all causes in the 22 town districts last week showed a decline of 19 from the number returned in the previous week, and included 22 which were referred to the principal epidemic diseases. against 18 and 21 in the two previous weeks; these 22 deaths were equal to an annual rate of 1.0 per 1000; in the 76 English towns the mean rate from the same diseases last week was 0.9, and in the eight principal Scotch towns was 2.5 per 1000. The 22 deaths from these epidemic diseases in the Irish towns last week included 10 from whooping-cough, 8 from diarrhea, 2 from diphtheria, and 2 from "fever" (enteric), but not one from measles, scarlet fever, or small-pox. The 10 fatal cases of whooping-cough showed a further increase upon the anumbers in recent weeks, and included 6 in Belfast and 2 in Limerick. The 8 deaths from diarrhoea also showed an increase, including 3 in Belfast and 2 in Dublin. Of the 2 fatal cases of diphtheria one each occurred in Dublin and in Belfast; and the 2 deaths from enteric fever included 1 each in Dublin and in Cork. The deaths referred in the 22 towns to pneumonia and other diseases of the respiratory system, which had been 110 and 101 in the two preceding weeks, rose to 157 last week. The causes of 14, or 3.2 per cent., of the deaths registered in these Irish towns last week were not certified by a registered medical practitioner or by a coroner; in the 76 English towns the proportion of uncertified causes of death last week did not exceed 0.8 per cent., while in the eight Scotch towns it was equal to 2.9 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Fleet-Surgeons: J. A. Moon, to Royal Marines, Portsmouth; E. B. Pickthorn to the Prince of Wales; M. C. Langford to the Medical Department, Admiralty; J. E. Coad to the Renown, on recommissioning. Staff-Surgeons: W. S. H. Sequeira to the President, additional, to be lent to Yarmouth Hospital, temporarily; A. Woollcombe, to the Charybdis, on recommissioning; R. F. Clark to the Brilliant, on recommissioning. Surgeons: H. W. W. Townsend to the Pembroke, for Royal Naval Barracks; N. P. Hingston to the Euryalus; J. C. F. D. Vaughan to the Haulbowline; H. C. Devas to the Cornwall; and J. Bourdas to the Pembroke, additional.

The following qualified candidates for the Naval Medical Service have been appointed Surgeons in His Majesty's Fleet:
—Martyn Henry Langford, Roderick Joseph Graham Parnell, Arthur Gordon Valpy French, Charles Dowall Bell, Archibald Fairley, John Parton Berry, Frank Lewis Smith, Walter Everard Lloyd, Francis Charles Searle, Albert Christoph Rusack, John Harding Baynes Martin, Cecil Gordon Sprague, and Thomas Charles Patterson (dated Nov. 5th, 1909).

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel H. Marks, on arrival in India, has been appointed to command the Station Hospital, Ferozepore. Lieutenant-Colonel W. Swabey assumed command of the Station Hospital, Aden, on Dec. 1st. Captain J. B. Cautley, Station Hospital, Cawnpore, has been directed to proceed to Bhamo for permanent duty in the Burma Division. Lieutenant-Colonel M. W. Russell has been appointed staff officer to the Principal Medical Officer, Eastern Command, vice Lieutenant-Colonel C. R. Tyrrell. The undermentioned officers, who are serving in India, are appointed specialists in the subjects stated: Captain J. H. Campbell, Brigade Laboratory, Allahabad, prevention of disease, from Sept. 14th; Captain A. H. Safford, Brigade Laboratory, Fyzabad, prevention of disease, from Sept. 16th; Major M. P. C. Holt, D.S.O., 3rd (Lahore) Division, advanced operative surgery, from Oct. 11th. Lieutenant-Colonel J. B. Forrest, returning from Burma, Major R. C. Thacker, from Karachi, and Captain W. MacDowall, from Ambala, have been appointed for duty in the Cork District; and Major E. S. Clark, from Nowshera, and Captain B. G. Patch, from Mooltan, to the Belfast District.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Supplementary List: Lieutenant Wilson Ranson to be Captain (dated Nov. 26th, 1909).

TERRITORIAL FORCE.

Royal Army Medical Corps.

2nd Home Counties Field Ambulance: James Dundas to be Lieutenant (dated Oct. 20th, 1909).

Lowland Mounted Brigade Field Ambulance: Lieutenant Robert B. Carslaw to be Captain (dated Oct. 7th, 1909).

2nd London (City of London) General Hospital: Major William H. White to be Lieutenant-Colonel (dated Nov. 9th, 1909). Captain Herbert P. Hawkins to be Major (dated Nov. 9th, 1909).

Attached to Units other than Medical Units.—Lieutenant Alfred A. Beeks to be Captain (dated May 26th, 1908). Lieutenant-Colonel John W. Ellis resigns his commission and is granted permission to retain his rank and to wear the prescribed uniform (dated Nov. 7th, 1909). Lieutenant John Hobbs to be Captain (dated Nov. 7th, 1909).

Hobbs to be Captain (dated Nov. 7th, 1909). For attachment to Units other than Medical Units.—Lieutenant Charles Henry Bullen, from the 3rd North Midland Field Ambulance, Royal Army Medical Corps, to be Lieutenant (dated Oct. 1st, 1909). Captain (Honorary Lieutenant in the Army) Edmund William Herrington, from the 3rd London (City of Lendon) Field Ambulance, Royal Army Medical Corps, to be Captain (dated Oct. 18th, 1909). Kenneth Mackinnon to be Lieutenant (dated April 1st, 1909). Percy Bertram Spurgin to be Lieutenant (date Nov. 16th, 1909).

DEATHS IN THE SERVICES.

Deputy Inspector-General Frederick William Blake, R.N.,

UNIVERSITY COLLEGE (UNIVERSITY OF LONDON).

—The new botanical laboratories will be opened on Dec. 17th at 4 o'clock by Mr. D. H. Scott, LL.D., Ph.D., F.R.S. The Vice-Chancellor will take the chair.

aged 85 years, on Dec. 4th. He entered the service as surgeon in 1846, became staff-surgeon in 1855, fleet-surgeon in 1870, and retired with the rank of deputy inspectorgeneral in 1879. He was assistant surgeon on the *Leander* during the Russian war in the Black Sea, 1854 (Crimean and Turkish medals).

Major Espine Charles Robert Ward, A.M.S. (retired), at his residence in Ireland, aged 61 years, on Nov. 28th. He entered the service in 1871 as assistant surgeon and became surgeon in 1873, surgeon-major in 1883, and retired in 1887. He served in the Zulu war in 1879 and in the subsequent operations against Sekukuni, including the storming of the stronghold (medal and clasp). He also served in the Boer war of 1881 and was present in the engagement at Madder Spruit, where he was slightly wounded (mentioned in despatches).

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

The December issue of this journal, which contains the index to Vol. XIII., opens with a short biographical appreciation of Sir John Pringle, Bart., from the pen of Major H. A. L. Howell, R.A.M.C. John Pringle was intended for a commercial career, but while on a visit to Leyden he attended a lecture by Boerhaave, which so deeply impressed him that he determined to become a pupil of that celebrated physician. He afterwards went to Paris, and subsequently returned to Edinburgh. In 1742 Pringle became private physician to the Earl of Stair, who at that time commanded the British forces in Flanders, and was also appointed physician to the military hospital there. He retired from the army in 1758. From a list of his writings Major Howell shows that Sir John Pringle was "unquestionably the father of modern military hygiene," and a study of his works "proves that he was aware of many facts in connexion with military bygiene which most of us have considered as of comparatively recent discovery."
"In conclusion," says the writer, "it is believed that to
Pringle is due the first foreshadowing of the Geneva Convention of our own day." In the same issue Lieutenant-Colonel R. J. S. Simpson, C.M.G., R.A.M.C., continues his medical history of the South African war; and the address on Some Modern Views concerning Heredity and Variation, by Brevet-Colonel R. H. Firth, R.A.M.C., which was recently delivered before the Aldershot Military Medical Society, is reprinted. Major P. J. Freyer, I.M.S. (retired), makes some practical observations on the operation for total enucleation of the enlarged prostate.

NURSES IN THE TERRITORIAL FORCE.

On Dec. 3rd Miss Haldane, sister of the Secretary of State for War, presented the badges to 110 nurses who have enrolled themselves in that force. The ceremony took place in the Royal Victoria Infirmary, Newcastle-upon-Tyne, under the presidency of Sir George Hare Philipson, consulting physician to the infirmary. After the presentation Miss Haldane gave an address on the Territorial Force scheme as it would apply to nurses, and outlined their duties and responsibilities. She congratulated the matron of the Royal Infirmary, who is the organising matron in the counties of Durham and Northumberland, on the success which had attended her efforts, and trusted that the full complement of nurses (120) from this district would soon be forthcoming. To this ceremony was added the presentation of prizes to the nurses of the infirmary as the result of their various test and certificate examination.

ATTACK ON AN INDIAN MEDICAL SERVICE OFFICER.

A Reuter's telegram from Lahore, dated Dec. 19th, states that Captain J. E. Clements, I.M.S., superintendent of the Central Jail, Montgomery, has been stabbed in the back and seriously wounded by a Pathan prisoner. The chief gaoler was also wounded in the stomach by the same prisoner. A later telegram states that Captain Clements has rallied and is going on well.

THE ARMY MUDICAL ADVISORY BOARD.

The Army Council has approved of the appointments of the following gentlemen as members of the Army Medical Advisory Board being renewed for a period of three years:—Dr. J. Rose Bradford, F.R.S., Sir C. Cameron, C.B., Dr. L. C. Parkes, Dr. M. S. Pembrey, and Sir F. Treves, Bart., G.C.V.O., C.B.

"Audi alteram partem."

ABDOMINAL CRISES IN DIABETES.

To the Editor of THE LANCET.

SIR, -- In THE LANCET of Nov. 27th is an annotation on the above subject recording two cases of diabetes in which an abdominal crisis occurred simulating acute intestinal obstruction, and it is mentioned that, although similar cases do not appear to have been reported previously, Grube has described in diabetes attacks resembling the gastric crises of tabes. The rarity of the condition leads me to think that a few notes of a recent case under my observation may be of interest. The patient was a lady, aged 25 years, who had been under my care during the last two years with severe diabetes. At first there had been marked improvement with alteration of diet and with the administration of sodium salicylate. The glycosuria rapidly diminished and there was great increase in weight. For 12 months she was able to resume carbohydrates, while continuing to take sodium salicylate. Then sugar reappeared, and she again came under my care in April, 1909. On this occasion, although similar precautions were adopted, there was not the same rapid improvement. The weight increased from 8 stones 4 pounds to 8 stones 11 pounds in three months, but the sugar never disappeared from the urine, diacetic acid and acetone were frequently present, and there was marked increase of the daily percentage of urea. To all outward appearance, however, she seemed well; she was always bright and cheerful and did not complain of fatigue. She returned to her home in the country in July, and I heard good reports of her progress until Oct. 30th, when she had sudden severe abdominal pain with slight sickness. pain was located in the lower part of the abdomen, and was suggestive of colic due to appendicitis, but it was not associated with rigidity of the abdominal walls, and it yielded in the course of 24 hours with the use of warm applications. As she had recently been exposed to cold it was hoped that the trouble might be merely a severe attack of intestinal spasm. Four days later, however, vomiting returned and became persistent; the diacetic acid and acetone increased, and the patient rapidly lost flesh and strength. When I saw her on Nov. 6th she was bright and cheerful, there was no localised pain over the abdomen, though there was a general sense of discomfort. She told me that the vomiting occurred suddenly without being accompanied by nausea. There was some headache, not severe, and the pupils were both moderately dilated and did not react to light on ophthalmoscopic examination. Within a few hours, however, she became comatose and gradually sank.

In view of the readiness with which patients with diabetes suffer from tuberculosis, the peculiar type of the vomiting at first led me to think of tubercular meningitis, but the optic discs did not support this hypothesis, there was no indication of paralysis beyond the sluggish nature of the pupils, and the ending was far more rapid than is customary. Vomiting has been mentioned as a precursor of coma, but it is not a frequent symptom, and when, as in this case, it appears to be primarily associated with severe abdominal pain, it is easy to understand that an erroneous diagnosis of appendicitis may readily be made.

To compare such cases with the gastric crises of tabes is, I think, rather unfortunate. The symptoms are, to my mind, far more suggestive of vomiting of toxic origin affecting the central nervous system.

I am, Sir, yours faithfully,

Harley-street, W., Nov. 29th, 1909.

NESTOR TIRARD.

THE VACCINE TREATMENT AND THE NEGLECT OF CLINICAL SIGNS.

To the Editor of THE LANCET.

SIR,—It appears to me that the system upon which the vaccine treatment of disease is being established gives cause for regret in that it asks but slight attention to clinical signs, though in the out-patient departments and in the wards of the hospital, physicians and surgeons have, till now, at any rate, been constantly urging their great importance before the

student. In some institutions, indeed, this modern treatment is being carried on somewhat independently of, or apart from, hospital work. In some cases the vaccine-therapist may scarcely have set eyes upon the patient. "Only let me have," says he in another case, "a sample of his blood, and I will treat his disease." This almost suggests the practice of the man who engages to supply the character of a person after merely studying a specimen of his handwriting. I deplore this neglect of the clinical method, and give herewith a marked instance of it.

Last week a lady was brought to me because of a glandular swelling beneath the upper part of her sterno-mastoid muscle, for the treatment of which she had previously been under the care of a highly accomplished vaccine-therapist. He had examined her blood, and at intervals had given her three injections of what I suppose was tuberculin, as, much to her alarm, he had told her that he thought her trouble was of tubercular origin—though appaswelling was slowly increasing in size, and she was now fearing lest an operation should be necessary. The case may well have been tuberculous, and she may have been ill-advised to leave the vaccine therapist to go to a general surgeon. But the point of my remarks is this, that whilst she was under his care he did not (as I was assured) examine the teeth or look into the mouth. On my making an inspection, however, I found a chronic abscess about the stump of the first lower molar tooth of that side, for which I advised immediate extraction. In my opinion this was the actual cause of the trouble, though I think it quite likely that the septic adenitis may have been followed by tuberculous invasion of the damaged tissue.

The time surely has not yet arrived that the vaccinetherapist can rise superior to those methods of investigation which are taught as the A B C to students as soon as they begin clinical work. It is far more important in such a case to examine the teeth than the blood, and a neglect to do so is apt to bring the newer methods into disrepute-methods which at present are still upon their trial.

I am, Sir, yours faithfully,

Great Cumberland-place, W., Dec. 6th, 1909. EDMUND OWEN.

THE THERAPEUTIC VALUE OF LIQUID AIR AND SOLID CARBON DIOXIDE.

To the Editor of THE LANCET.

SIR,—We have read with interest the paper by Dr. Reginald Morton in your current issue on "The Treatment of Nævi and other Cutaneous Lesions by Electrolysis, Cautery, and Refrigeration." To his main thesis we do not wish to take any exception, but we beg to differ from him as to the usefulness of liquid air. He says: "It is extremely difficult, even impossible, to use it in an efficient manner. Its liquid form is responsible for this, making it difficult to control, and impossible to make use of that most important adjunct—pressure." We have made an extensive use of this agent during the past two years in the treatment of lupus erythematosus, nævi, and "port-wine stains" with very gratifying results, and have not found that difficulty in using it which Dr. Reginald Morton indicates. We apply it by means of a piece of absorbent cotton-wool wrapped round the end of a small cane about 10 inches in length. This is immersed for about a minute in the liquid air in a Dewar's bulb, and on withdrawing it the wool is found to be saturated with the fluid. The wool is then pressed firmly against the part to be treated and no difficulty is found in graduating the pressure to the required degree. For superficial cases we have found solid carbon dioxide very good, but the action of liquid air is, in our experience, superior. - We are, Sir, yours faithfully,

Liverpool, Dec. 6th, 1909.

STOPFORD TAYLOR, R. W. MACKENNA.

THE INFLUENCE OF DIET ON THE THYROID GLAND.

To the Editor of THE LANCET.

SIR,-I should be very sorry indeed to think that I had allowed an inaccuracy to appear in my letter of Nov. 22nd, but even after reading Dr. Chalmers Watson's comments I cannot admit that this has happened. The words I used were that "excessive meat-eating is a subject that has attracted a

whole host of investigators," but they are now repeated by Dr. Watson as "a whole host of investigators have made a special study of the direct influence of diet on the thyroid gland." This elaboration and qualification do not come from me, and if, in its revised form, the statement is misleading the responsibility is not mine.

Dr. Watson clearly wishes to maintain that his experiments must be compared only with those undertaken subsequently to his own and with the special object of ascertaining the direct influence of a protein diet on the thyroid. They must not be compared with any of the earlier work dealing with the effects of a protein diet from any other standpoint. Can Dr. Watson have forgotten his own writings? He has told us that his "research was primarily an experimental investigation into the nature of avian gout and the changes in the thyroid and parathyroid glands were, so to speak, an accidental finding." I do not wish for one moment to minimise the interest of his researches, but it would be incorrect to suppose that the effects of protein diets, whether in excess or the reverse, received no attention until he began to write his papers. For more than half a century this subject has been under investigation, and he need go no further than the ordinary catalogues and indexes of scientific literature to find the references for which he

To the second part of my statement, that no other investigator has produced the enlargement and microscopical changes in the thyroid, I must also adhere. Again I cannot do better than quote Dr. Watson himself who, in recording his results,2 claimed that "this is the first time that there has been induced experimentally in animals an enlargement of the thyroid gland." He now brings this statement up to date by the addition that I am the only investigator who since 1904 has experimented on the subject. He forgets that in the discussion that followed his paper before the Pathological Society in 1906, Mr. Edmunds brought forward a series of his own in which he fed rats on a purely protein diet, but failed post mortem to find any change in the thyroid gland.

I am, Sir, yours faithfully, DAVID FORSYTH. Queen Anne-street, W., Dec. 6th, 1909.

CIVILISATION AND THE CORSET.

To the Editor of THE LANCET.

SIR,-The tendency to-day to abandon artifice and live more naturally has always appeared to me to be a most hopeful feature of modern civilisation. This is especially so in dress, a field in which artifice abounds, often to the detriment of health. As one therefore who has for some years supported the crusade against corsets, I wish respectfully to protest against the views expressed by Mr. Heather Bigg in your issue of Nov. 27th. That the corset may be of great remedial value I should be the first to admit, and, in fact, could hardly deny in the face of such an authority as Mr. Arbuthnot Lane. I gather, however, from his article on the subject that he urges its therapeutic value rather than its general use.

Mr. Bigg in his letter begins by saying that women have found by experience that corsets are indispensable. How then does he explain the fact that the experience of many women to-day is that they are better in health, and far more comfortable, for having abandoned them, and that those who are brought up from childhood without them never feel the necessity for them? He gives the extra abdominal organ as a special reason for women needing corsets; but if a corset is effectively to drive out waste blood from the abdominal viscera, surely it would divert the pressure produced by the downward movement of the diaphragm, from its general distribution forwards and downwards, to a direction entirely downwards, and so be an increased strain on the extra organ in question. Mr. Bigg says that nature has ordained women to breathe pectorally, but surely artifice, not nature, is responsible for this. Modern physiology uphoids the view that the corset is the cause of pectoral breathing in women. Hutchinson, in his "Applied Physiology," p. 195, makes the following statement:—"It is now generally admitted that this type of breathing in women is due to the wearing of corsets." The breathing of women who do not wear corsets bears this out, for it is as much abdominal and as little pectoral as in man.

¹ THE LANCET, 1907, vol. ii., p. 254. ² THE LANCET, vol. i., 1905, p. 347.

For healthy women to wear corsets habitually for the purpose of driving stagnant blood from the abdominal viscera seems to me to be an advantage entirely outweighed by the disadvantages of impeded respiration and restricted movement; and I cannot but think that the support of natural muscles, aided, if necessary, by suitable exercises, attains this end quite sufficiently. That a corset, however wellfitting, does impede breathing can be easily tested. Let any woman attempt to fasten her corset in its usual dimensions while holding her chest in a position of deep or even moderate inspiration and she will usually fail to do so. If she can do so, which is unlikely, the corset is useless for the purpose of increasing abdominal pressure.

In conclusion, I would ask at what age Mr. Bigg considers it advisable to begin wearing a corset. If the erect posture demands it, then we should be wise to put our babies into stays as soon as they begin to toddle. God forbid!

I am, Sir, yours faithfully,

West Worthing.

CECIL E. FISH, M.B. Cantab., Vale of Clwyd Sanatorium, N. Wales.

SACCULI NOT DIVERTICULA.

To the Editor of THE LANCET.

SIR,—It was my good fortune to be present at a demonstration by Dr. W. H. Maxwell Telling on the disease of the colon with which you have associated his name in THE LANCET of Nov. 27th. After his demonstration I explained my views of the condition, and I believe that they met with his acceptance. They were expressed in the "Medical Annual" (Wright), 1909, p. 210, as follows:—

met with his acceptance. They were expressed in the "Medical Annual" (Wright), 1909, p. 210, as follows:—

"Diverticula" of the colon, especially of the sigmoid, have been long known to pathologists. Only recently has their surgical importance been recognised, and chiefly as a cause of left-sided intra-abdominal suppuration or as "tumours" of the sigmoid which have been mistaken for cancer. More obscurity than probably belongs to the subject has arisen from the use of the term diverticulum as applied to these protrusions from the bowel, and small consideration shows that between them and the recognised diverticula there are many points of difference. It seems probable that all diverticula are of congenital origin. All coats of the intestine enter into their composition. All have a special vascular supply of their own. They are seldom if ever multiple, and are found at any age. The vermiform appendix is representative of this type in the normal subject. Meckel's diverticulum, due to arrested involution of the omphalomesenteric duet, has long been recognised as of surgical importance, and the existence of diverticula at different portions of the gastro-intestinal tract associated with small panceratic outgrowths has been recently added to our knowledge of these interesting conditions. Of the traction diverticula due to the drag of a limited adhesion, nothing more needs to be said than that they ought to be classed separately from any other form.

The swellings observed on the colon do not answer to our description of a diverticulum at all; indeed, their origin is so different that the confusion caused by calling them diverticula should cease. They differ from diverticulan that they are never of congenital origin, and have consequently not been found in youth; are multiple; thin-walled, because the muscular coat of the intestine is usually absent in them; they are counted in shape, do not attain to large size, and are practically limited to advanced life. In the urinary blaider, other parts of the gastro-intestina

ANNUAL MEETING AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

To the Editor of THE LANCET.

SIR,-In your report of this meeting an inaccuracy so serious appears that I am sure you will correct it in your next issue either by inserting a correcting paragraph or this letter, as you may think the better thing to do. I refer to the following: Dr. W. G. Dickinson asked the President

report of the College at page 9. Your report states that the President replied that "the body corporate" consisted of the past, present, and future Fellows and Members. As I was present I can vouch that what the President actually said was "the body corporate consists of the past, present, and tuture Members of the College." This is the reply also reported in your medical and lay contemporaries. There is a vital difference between your report of what the President said and his real reply.—I am, Sir, yours faithfully,

SIDNEY C. LAWRENCE, M.B., D.P.H., M.R.C.S.,
Honorary Secretary, Society of Members of the
Royal College of Surgeons of England.

Lower Edmonton, N., Dec. 7th, 1909.

THE HARD CASE OF THE LONDON STUDENT.

To the Editor of THR LANCET.

SIR, -- After reading your excellent articles on medical education one feels that, indeed, the medical world is "out of joint." Main issues are so often missed, and as regards Main issues are so often missed, and as regards the question of "degrees for London students" the main

issue is usually passed over.

The M.D. degree of most universities involves only a medical training. The degree is considered academic because it is conferred by a university. The arts and science training required are practically the same as for a licence. No degree in arts is taken in most instances, and excepting for preliminary work the whole training is technically medical. "There's the rub." With similar conditions of curriculum and examination there is a difference in title and in name which leads to jealousy and confusion. I place our great London medical schools on an equality with the medical departments of most universities, and I hold that those of us who took respectable positions in the class-work and examinations of those schools, and also took our licences to practise, are in no sense the inferiors, either in training or position, to the graduates of medical departments of universities. That the examinations of some universities go beyond the ordinary grade is true, and men holding those degrees are credited with the position their work has gained, but that any invidious distinction should be made in title or otherwise between the graduates and diplomates of approximately equal standing is absurd and unreasonable. The question stands thus. Is it just that London students who have passed through the training and examinations of a medical college equal in every respect to the constituent medical colleges of most universities, who have also passed examinations for qualifying diplomas recognised by the General Medical Council as sufficient to ensure registration on equal terms, shall be allowed to suffer under a technical disability in the eye of the public? It is not just! There can be no other answer.

The remedy is not far to seek. All that is required is the mill to remove the evident injustice, and a disposition to sink small jealousies and petty self-seekings.
I am, Sir, yours faithfully,

Loughborough, Dec. 4th, 1909.

J. B. PIKE.

THE INFLUENCE OF MIND AS A THERAPEUTIC AGENT.

To the Editor of THE LANCET.

SIR,-In his remarks on Dr. Morison's views concerning the influence of mind as a therapeutic agent Mr. J. Foster Palmer would seem to condemn hypnotism entirely. The sentence, "when hypnotic suggestion takes the form of inducing the patient to believe what sound reason tells him to be impossible," might be taken as an admission that this is not always the case, but other passages, in which hypnotic suggestion is termed "induced insanity," "criminal offence," "the more execrable" because enfeebling the already feeble-minded, leave no doubt that the condemnation is intended to be absolute.

I will not enter into doctrinal considerations, but it may be pointed out that hypnotism does not always mean enfeeblement of will. A patient may, with the sane part of his mind, desire a healthy ideal, but may be kept, nevertheless, in hopeless degradation by a morbid obsessive idea. In such a case—chronic alcoholism, for example—rational persuasion, as we all know, may fail utterly, whereas the interwho were "the body corporate" referred to in the annual mental influence of hypnotic suggestion may strengthen the mind against unhealthy impulse, and often cures such cases definitely, twice in my experience in the course of five minutes. Such a result can scarcely be termed "parting with reason." In Dr. Morison's excellent letter there are, it is true, as in Mr. J. Foster Palmer's, sentences which read separately contradict one another, but taken as a whole the meaning of the writer is quite clear. Rational persuasion is to be preferred, but "for those in the portice of the lunatic asylum" any kind of make-believe is better than insanity. Delusive methods are, however, seldom necessary, for an intermediate plan which is neither simple rational persuasion nor make-believe deception is available. This is the elimination of error and the credencive induction by hetero-influence of the right and the reasonable. But I cannot see what objection there can be to inhibiting absolutely by hypnotic cambriolage the impulses of a hopeless inebriate, if he cannot be rescued from slavery by any other I am, Sir, yours faithfully,

Paris, Dec. 5th, 1909.

MORAL ORTHOPÆDIST.

APPRENTICESHIP.

To the Editor of THE LANCET.

SIR,—The discussion by the County Council of the report of its education committee on the extent to which the scholars at London's elementary schools drift into unskilled labour, coupled with the interest of Sir John Knill, the new Lord Mayor of London, in the matter of apprenticeship points to a serious effort being made towards the organisation of apprenticeship under Government auspices. As you have given space to the debate at the London County Council I think you may be willing to publish a few words from one who is interested in the movement as a practical worker. There is a risk lest what is being really aimed at, which, by the way, has a large medical side, should be misunderstood.

The Lord Mayor seems to be in favour of a revival of apprenticeship under old conditions, when apprentices "lived in," but the public does not appreciate that by these words the modern sense of the term "living in" is not implied, under which adult shop employees are housed together on the premises of the shop or in dormitories in neighbouring buildings. The revival of the old apprenticeship system would make a lad a member of his master's family, sharing the family life and meals. Surely a revival of this system is impossible, and it would be a pity that anyone should confuse a very modern movement towards technical education with impossible medievalism. No apprentice would in these days either consent to or be allowed to sleep under the shop counter or in any odd corner of the premises. Decent sleeping accommodation would have to be provided for him, and where the master lived over his place of business sufficient space would as a rule be unavailable, while where the master lived in a suburb the whole principle of such "living in" would be altered, if only because the expense to the apprentice of travelling to and fro would not be compensated for by his "living in." In the olden days of apprenticeship, the lad, being a veritable member of his master's family, received the same moral guardianship as the members of that family, but this would not now be possible for numerous reasons, one being that the employer of labour often delegates his responsibility towards his own children in this direction to a schoolmaster. It is probably desirable that boys and girls just leaving school should continue to live with their parents; it is wrong that they should live anywhere where they are not under supervision.

Let us, then, leave "living in" out of the question. Apprenticeship in London in the future cannot as a rule be associated with any such practice, but must be a system under which the boy or girl beginning business is placed during working hours, with some arrangement about premium, for a definite time with an employer. It has been urged by some interested in this matter that trade schools are a better solution of the question how to increase the amount of skilled labour in this country than any attempt to revive apprenticeship, and the hygienic conditions under which children are taught in these schools are certainly superior to those existing in the average factory or workshop. The large factory run by a limited liability company, where no interest would, or could, be taken in individual apprentices, is not under consideration; at such places the

hand is only taught one process and never learns a complete The fact that general education is continued in the trade schools, so many hours per week being given to it, is an important point in their favour. Here we have something to replace the interest in the general welfare of the apprentice that was manifested by the old-time masters. trade schools could become a complete and full organisation I grant that the system would be ideal; but expense alone makes this impossible, and some form of apprenticeship must go hand-in-hand with trade schools. As an alternative to the general education in trade schools we have evening classes, but they require cooperation on the part of the master, and also a great deal of care is called for from the parents, so that overwork may be guarded against. Also at these schools there is always a temptation to work at subjects connected with the apprentices' trade and not at general education. Mr. Cooper, speaking from the labour benches in the County Council debate on the subject, urged that a larger supply of skilled labour will not create the demand seems unfortunate for two reasons. First, the foreigner is often to be found in London in positions of trust as the foreman or the skilled workman performing the more highly-finished and difficult processes in a workshop, pointing apparently to the fact that there does not exist a sufficient supply of Englishmen to fill such posts. I do not know how far this is general, but two trades occur to me where British workmen are found in inferior positions—viz., that of the optician and the ladies' tailor. Second, if the young skilled workman cannot find work at home, surely he might seek it in many colonies. The ranks of unskilled labour may there be as overfull as they are at home, but the master of his trade should surely have a better chance of finding a market. It is because so many of the unemployed become a medical charge on the community that I address this letter to you. So many of the unemployed unfortunately become sooner or later "unemployables," filling our infirmaries and hospitals and putting a heavy burden on the shoulders of the skilled and thrifty among the community. authorities, those of the Poor-law and those of the charitable organisations and hospitals alike, which deal with such problems feel that every year it becomes of more importance from the public health point of view that a greater security of return should be enjoyed by the wage-earning classes. The apprenticeship movement is towards a better equipment. mentally and morally, of the youth of this country, and medical men might well give it their support and sympathy. Both properly run trade schools and properly organised machinery for apprenticing children on their leaving school are desirable from a public health point of view.

I am, Sir, yours faithfully,

A WORKER ON THE APPRENTICESHIP AND SKILLED

Dec. 1st, 1909.

EMPLOYMENT ASSOCIATION.

NURSING ASSOCIATIONS AND MIDWIVES.—At the annual meeting in London on Dec. 1st of the Sussex County Nursing Association Mr. A. G. R. Foulerton, medical officer of health of East Sussex, stated that instead of losing 10 infants out of 100 in East Sussex last year they had lost 6 or 7, and he attributed this low mortality to the good nursing of the maternity nurses from the association. Further, out of 1800 women of the working classes attended in confinement only 4 died, death being absolutely unpreventable in 3 cases. These figures point to the good work of the Nursing Association, and those boards of guardians who do not, as they are legally empowered, subscribe towards the association are to be urged to make a contribution. Boards of guardians will probably find in the near future that it will be far more ecomomical to support these nursing associations than be compelled to make provision for innumerable maternity cases, for in April next, when the Midwives Act of 1902 comes fully into operation, no untrained women will be permitted to practise. Dr. F. H. Champneys, chairman of the Midwives Board, who was present, said the great difficulty in the question of midwives was in the rural districts, but of the 1408 successful candidates since April last 33 per cent. intended practising in the rural districts. That showed, he added, a steady influx of the women they wanted, who were prepared to practise among the poor. There was no reason to fear a serious shortage until April next, but a redistribution might be necessary and should be

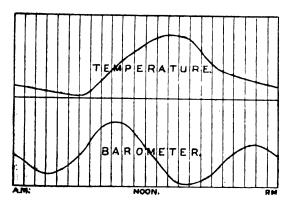

THE PRESERVATION OF DRUGS AND INSTRUMENTS IN THE TROPICS.

(FROM A BOMBAY CORRESPONDENT.)

THERE are certain things which the medical man who has never lived in the tropics can hardly realise, but these things should be known to our colleagues at home, that they may appreciate the difficulties under which some of our work is done.

We cannot open a bottle of compressed drugs without being reminded, by the care bestowed in sealing it, of the risks to which the contents are exposed in tropical countries. Metallic capsules, paratin-soaked corks, and absorbent cotton-wool within the bottle, would appear to ensure safety, but it seems to be only a matter of time for moisture, the great enemy, aided by heat, to modify, and in some cases to destroy, the value of the contents. The packing is doubtless performed with every known precaution and the drugs are freshly dried; still damage occurs in a period which varies with local conditions. Bombay, Colombo, and Singapore may be taken as typical of the worst localities where heat, light, and moisture combine to produce the most destructive effects upon all organic substances. Vegetable drugs in the form of leaves and roots, although compressed tightly in bales, cannot be stored for many weeks during the monsoon without being attacked by fungi which destroy the parts affected. Deliquescent salts by the absorption of moisture alter their weight value and compounded drugs in time lose their value by the chemical interaction of their constituents.

The penetration of moisture into closed vessels is due to two principal causes. The daily fluctuation of temperature in the air produces an alteration of volume, which passes from a minimum just before sunrise to a maximum between half-past 2 and 3 o'clock in the afternoon. If we assume a daily range of temperature equal to 15° F. the alteration in volume of the free air would be almost 3 per cent., but if enclosed in an air-tight and rigid vessel it would produce a pressure equal to 60.42 pounds per square foot of internal or external pressure, according to the hour at which the vessel The other cause is due to changes of barowas sealed up. metric pressure that take place twice daily, having their maximum at about 10 o'clock, morning and evening, and their minimum at about 4 o'clock, morning and afternoon. The ordinary range is one-tenth of an inch, but it extends to half an inch at times, and when the barometer falls to that amount the internal pressure on a box, a glass case, or bottle, if tight and rigid, is increased by 35.2 pounds per square foot. The enclosed air, if allowed to expand, would increase by 2.8 per cent. The subjoined curves represent the mean diurnal fluctuation of temperature and barometric pressure at Bombay; the vertical lines, representing hours, enable the reader to observe how they act in relation to each other

The two influences of temperature and pressure act in opposition to each other from about 6 in the morning in Bombay until 9.30. From this time until 3 P.M. their joint influence is in favour of expansion, and afterwards until 10 P M. their joint action causes reduction of volume. After this and until 6 A.M. they act in opposition. They rarely balance each other, and the result is an almost constant | The result is a flexible cylindrical cap fitting on to a rigid

change of volume and temperature throughout the 24 hours. and with these a constant change of atmospheric humidity. A movement of air is thus set up in all imperfectly closed vessels that carries water vapour in and out, and if any absorbent material lies within the vessels it is likely to absorb moisture to some extent. The same influence that carries in moisture introduces dust, but whilst some of the moisture may be carried out again the dust remains as it falls in the still atmosphere within. Absolute and permanent airtightness seems only possible when the vessel is of metal and closed with solder. The extreme changes to which goods sent from England may be exposed in the tropics is indicated in the subjoined table, which shows how much water in a state of vapour may be contained in a cube of air with a side of 10 feet when saturated :-

In London the mean annual temperature is 49 · 2° F .. while that of Bombay is 79 · 13°. The mean relative humidity in these places is 82 and 77 per cent. respectively. By reference to the above table it will be found that the corresponding weights of water vapour are 0.57 and 1.135 lb., the latter being 2 · 22 times the former. On August 3rd of this year the moisture in the air of Bombay weighed 1.56 lb. per 1000 cubic feet.

The various modes of closing bottles and other vessels with wax, paraffin saturated cork, rubber rings or washers. are all affected by changes of volume, temperature, or humidity of the air, that swell, shrink, crack, or decompose them. The evil effects of air leakage are most apparent in vessels that are not full. A vessel whose contents leave 50 per cent. of air space would be liable to a leakage of 1.43 per cent. of its contents under a change of temperature equal to 15° F., and, in the rainy season, when the air often contains 1.2 pints of water in vapour form per 1000 cubic feet, it is not difficult to imagine how the breathing action of any imperfectly closed case may affect its contents. Stores in India may, for many days together, contain an atmosphere of this kind, and the only mitigation possible is the admission of ample light with free ventilation as soon as the outer air is found to have become less moist. Absolute dryness in the air of a closed package may be left out of practical consideration on account of the extreme difficulty of obtaining it, but as all materials may be preserved in good condition for a certain time in an atmosphere containing some moisture it will suffice to consider the available means for this purpose. And as a soldered tin case is recognised as the most completely closed vessel, attention will be mostly directed to vessels having lids that must be opened occasionally, even if at long intervals. The tightness of barrels is far from complete in India. If filled with water or with any watery liquid there is a steady evaporation through the wood unless it is kept in a very damp atmosphere; if filled with oil and exposed to the sun or to a dry wind the oil will begin to leak owing to evaporation of moisture from the wood which the oil does not replace. Boxes built of wood, whose grain lies in different directions, cannot be kept airtight owing to shrinkage and swelling, due to changes of atmospheric humidity. grain of the lid and the sides of a box do not all lie in the same direction, and as paint or varnish are no complete protection against the penetration of moisture the movement of shrinkage and swelling in time causes air leakage.

Tin and other rectangular boxes of metal always leak at the joint of the lid, whatever may be said to the contrary. The tightest metallic cover joint, setting aside those that are closed with the aid of screws, is made like that of a tea or coffee canister, but with the following difference. The neck, about 13 inches high, is tapered with a slope of one-sixteenth in two inches. The cap or cover may be four inches deep and is cylindrical in shape. The edge of the mouth is not stiffened by folding. It must fit tight over the neck when pushed down to within half an inch of the shoulder of the box. The joints of the sides of neck and cap that come in contact must be quite smooth and even.

conical neck, forming a true contact joint all round which may be closed tight without sticking. A little oil or vaseline facilitates the use of this lid. Within the lid is a small hook of wire on which may be hung a bag with quicklime to absorb moisture from the contents of the box, which may be made square or round. The lid may be made up to 9 inches in diameter. This box has seen many years of service in Bombay for the preservation of the most diverse materials.

Although rectangular tin boxes do not close well, and wooden boxes have the faults already mentioned, a very useful combination may be made of the two materials, the one supporting the other. A useful dry chest may be made from a good packing case of suitable size. The case is put in good repair and closed. The lid is then cut off, along with three or four inches of the body to form a ledge. The sawn part of the body is then planed true and level, and rubbed with chalk. The lid is similarly treated until when rubbed on the body the chalk mark is transferred all round. The hinges are applied from the outside and screwed in place while the lid is pressed down with weights. The interior of the box and lid are lined with tin-plate or zinc, which is tacked round the edge of the lid-joint, but does not encroach upon it. Hooks are added on the outside to keep the parts in close contact when shut. A small amount of quicklime in a box or bag placed near the top of the box will keep the air dry enough for the protection of books, papers, instruments, and other things. Protection against the white ant may be obtained by painting the exterior of the box with mineral spindle oil, which is worth about 20 pence a gallon. This oil sinks into the wood and imparts such a bitter, unpleasant taste to it that vermin avoid it.

The preservation of instruments, especially if made of steel, has of late years received attention in India, as may be seen in the use of nickel plating and of metallic racks for holding them. Leather, velvet, and cloth linings for instrument cases are still much used, and as these materials are all very absorbent they communicate moisture readily to all unprotected steel surfaces and to cutting edges, such as lancets, knives, and hypodermic needles. From information obtained among operative cutlers it appears that surgical instruments are very much neglected in India, especially among medical men trained in the country. The dirty condition in which they often arrive for repairs indicates gross carelessness which may have caused many an unrecorded disaster, and as leather- and velvet-lined cases are the most commonly used the exposed steel surfaces are often pitted with rust. The people of India, who will make any sacrifice for the sake of creemonial purity, are very indifferent to many of the requirements of cleanliness and sanitation.

Next to plated metal the best material for cases seems to be wood that has been soaked in paraffin wax by immersion in the hot material, and stoving until the surplus drains off. Bay-wood so treated gives good results either for the case itself or for linings and trays. It must be dovetailed, nailed, or screwed together, as glue will not adhere to it. Vaseline has been found to offer less protection to fine instruments than what is known as neutral oil, which would seem to imply that the vaseline has not been properly washed after refining.

Preservation of goods by cold storage has made little progress in India, although the 30° increase of average temperature above that of England renders it so much the more desirable, but it is, for the same reason, more costly than in a temperate region. Cold stores will become a necessity in India as soon as the fish supplies of our large sea-coast cities are obtained in a modern and systematic manner, and then the importers of drugs and instruments that suffer deterioration may insure their property against loss while in stock.

PROPOSED ADDITIONAL ASSISTANT MEDICAL OFFICER FOR THE LONDON COUNTY COUNCIL.—At the meeting of the Education Committee of the London County Council on Dec. 8th, the general purposes sub-committee presented a report upon the work of the medical department (education), and recommended that to meet the increasing pressure an additional assistant medical officer in the public health department should be appointed at a commencing salary of £500 a year, rising by annual increments of £50 to £700 a year. The consideration of the report was postponed.

DISPOSAL OF SEWAGE IN TORONTO.

(FROM A CORRESPONDENT.)

TORONTO is situated on the northern shore of Lake Ontario, facing south, on a plateau gently ascending north for a distance of three miles, when an altitude of 220 feet above lake level is reached. It extends for a total distance about eight miles along the lake. The topography is fairly uniform, with an even slope to the shore. The most populous portion of the city extends for a distance of about two miles along the shore of the harbour. This harbour is a natural basin formed by a sand ridge known as The Island, which encloses it on the south and partly on the west. The mainland on which the city stands is its northern boundary, while the eastern part of the harbour is bounded by marshy land through which flows the river Don. The harbour is roughly semicircular and about one and a half miles in diameter. It has two openings, one on the west between the mainland and the island, a distance of less than half a mile, and a considerably smaller entrance to the east, named the Eastern Channel. Owing to the narrowness of these channels the water is practically stagnant.

Since the year 1833 or thereabouts, when Toronto was known as York, its sewers have emptied themselves into the harbour. In 1834 Sir R. Bonnycastle, who made a report concerning the state of the harbour, advised that the sewers should not be constructed so as to discharge into it. Mr. K. Tully, previncial surveyor, wrote as follows on the same subject in 1855: "The deposits from the sewers of the city into the harbour are much more considerable than would at first be supposed. From experience in the construction of wharves, &c., it has been found that from Conge-street, on the west, in distance about midway of that part of the city fronting the harbour, to the river Don on the east, the end of the harbour, the average depth of deposits from sewers alone is not less than two feet; taking the distance to be 5000 feet, with an average breadth of at least 300 feet, we have a quantity equal to something like 100,000 cubic yards, a very serious amount considering it only extends over a period of 20 years." Mr. Tully also recommended that the sewers should no longer be led into the harbour. Matters, however, remained as before, and when the fact is taken into consideration that during these 70 years Toronto has immensely increased in area and that its population has advanced by leaps and bounds the condition of the harbour at the present time may be easily imagined.

The sewerage system of Toronto is fairly complete for collecting sewage and rain water. It is what is known as the combined system, with the exception of an outlying suburb, which has a separate system and which will be described at the conclusion of this paper. Most of the sewers run in a southerly direction at right angles to the shore of the lake and harbour, but a few run east and west. The general result is that two-thirds of the sewage is discharged into the harbour. Those sewers which run at right angles to the lake are generally kept well cleansed by storms, but those on the east and west streets have gradients too flat to cleanse themselves, and have to be flushed more or less by artificial means. Two large sewers discharge into the lake to the west of the harbour, the larger one of which was originally a creek (Garrison Creek), but has been converted into a sewer. There are about 290 miles of sewers which are admittedly well kept and excellently supervised by the city engineer and his staff. Gaugings taken of the dry weather flow in the main sewers in 1908 showed the quantity to be about 73 gallons per head.

There are, then, two valid reasons why the harbour should not be utilised for the disposal of sewage. One is that it is in close proximity to the most populous part of the city, being in the summer time traversed by steamers and boats, the routes of which are marked on the map and to whose passengers the odour alone is offensive. The other and by far the more important reason is that which concerns the water-supply. A considerable part of the water-supply of Toronto is derived from the lake by means of pipes laid on the bottom of the harbour which cross the island, the intake being at a distance of nearly 2000 feet from the southern or outer shore of the island. As already mentioned, the bottom of the harbour is covered to a depth of some feet with sewage

deposit; it is therefore always possible that the contents of the pipes may become contaminated by accidental leakage, and in any event the intake of the water is too near the

deposits of sewage.

In 1907 there was a good deal of agitation in connexion with the water-supply, and the medical officer of health, in addition to making the usual bacteriological examination of the water, also had it analysed during the three autumn months. The results were not satisfactory, and he advised that the citizens should boil the water before using it for drinking purposes. This warning further alarmed the inhabitants, who demanded filtration of the water-supply, and from that date no strong objections have been brought against providing money for schemes calculated to ensure as pure a water-supply as possible. But action in Toronto, I am glad to say, did not have its origin in a scare. The movement for securing better conditions than those existing took practical shape about 20 years ago, for in 1889 Messrs. R. Hering and S. Gray, well known civil engineers of New York, were called in by the city authorities of Toronto to advise as to an extension of the water-supply and the disposal of the sewage. They naturally said that if it were desired to continue the water-supply from the lake the sewage must be removed to a location so far distant from the intake that there could be no possible fear of contamina-

tion from this source. They pointed out that there were two alternative methods of dealing with the sewage. One was land treatment, which they dismissed as being too expensive and as requiring too great an area of land. The other alternative was discharge of the sewage into the lake at a point outside the harbour either in a crude state or after artificial treatment, and they decided in favour of discharging the sewage in a crude state into the lake at a somewhat considerable distance from the citv. They re-

commended for this purpose that two large intercepting sewers should be into the lake to a distance of 3500 feet from the constructed, the first of which, or high level sewer, should intercept the drainage of the greatest area that could be economically conducted to the outfall by gravity, while the second, a low level sewer, should intercept those sewers which did not run into the higher one.

With certain modifications these plans are to be closely followed, and it was decided some few months ago that the work of constructing the high level sewer should be commenced. The present plans provide for the building of two intercepting sewers which will run parallel to the shore from Garrison Creek sewer, slightly to the west of the western end of the harbour to a point nearly at the eastern extremity of Ashbridge's Bay, a distance of two miles from the harbour. The departures from the plans of Messrs. Hering and Gray are that the sewage is not to be discharged into the lake in a crude state, but is to be treated in the vicinity of the outfall which will be nearer the city than that suggested by Messrs. Hering and Gray, for which purpose sufficient land has been purchased. Owing to this fact the intercepting sewers will not be so long as those proposed by the New York engineers, but in all other essential details the plans are practically identical.

Calculating somewhat roughly, the high-level intercepting sewer will be placed at an average distance from the lake shore of between 2500 and 3000 feet. This sewer will receive

the drainage of the whole of the district to the north, that is to say, the sewage of by far the greater part of the city. low level sewer is to be situated at a distance of 2000 feet or so from the high level sewer, and is intended to intercept the drainage between the two intercepting sewers, largely trade waste, for although factories are not numerous in Toronto as yet, the city is developing and no one can set bounds to the directions or extent of its progress. The intercepting sewers are to be constructed of brick and concrete, and will receive only the dry weather flow, plus a small quantity of rainfall; the excess during heavy rains will be allowed to continue its natural course. No house connexions will be taken into the interceptors, all sewage entering at street intersections, where the main sewers meet the interceptors. The high level intercepting sewer will vary in size from 6 feet to 10 feet in diameter, and will be so laid that the contents will have a velocity of 4 feet per second. The maximum diameter of the low level intercepting sewer will be 5 feet. Both the intercepting sewers will be five and a half miles in length, and in their course will pass under the stream at the east end of the harbour, named the Don. The low level intercepting sewer will be pumped into the channel at the disposal works near the outfall, the channel carrying the drainage from both intercepting sewers into a small basin, when

treatment will follow. First, the sewage will be run through screens, which will remove the coarser matter in suspen-sion, and will be then passed into sedimentation tanks, which are to be built "hopper' shaped, somewhat after the style of the "Dormund" tanks, and similar to some of the sedimentation tanks now installed in Birming-ham. The liquor after remaining in the tanks for the usual period of three hours will be discharged over weirs into effluent carriers and will flow by gravity into the main carrier which will convey the sewage thus treated

RIVER DON SWI MI ESTERN CHANNEL ₽O!H 0 В R 0 LAKE ONTARIO

Sketch map of the harbour and island of Toronto.

shore. It may be stated that the lake at this point is 30 feet deep. The part of the lake from which Toronto derives its water-supply is distant about five miles to the west of the site of the proposed sewage disposal works, and observations have shown that the trend of the lake current is chiefly in an easterly direction—that is, in a direction away from the intake. It is considered that the high level intercepting sewer, which will be completed, it is estimated, in two years' time, will be capable of conveying the sewage of the greater part of the city to the disposal plant, thus relieving the harbour to a very large extent. When both sewers have been built and are in working order the entire mass of the sewage will be removed beyond the danger zone. The above is a broad description of the sewerage system which is to be introduced into Toronto. It should be stated that Mr. R. Hering of New York and Mr. J. D. Watson of Birmingham, England, visited Toronto some few months ago to consult the city engineer and to advise on the proposed system for disposing of the sewage, and that both cordially approved of the plans about to be carried out.

Owing to the impossibility of connecting the Woodbine district to the East of Toronto, which had no drainage system, with the city sewers, and owing to the rapid increase of population in the district, it was found to be absolutely

necessary that something should be done to improve its sanitary conditions. The municipality of East Toronto procures its water-supply from a point three-quarters of a mile east of this district and as the board of health objected to crude sewage being deposited in the lake, it was decided to lay a sewerage system and to construct septic tanks and bacteria beds to treat the sewage. The drainage area of the district is 185 acres and the population in the summer is in the neighbour-hood of 11,000 persons. 18,000 feet of sewers were laid to convey an estimated sewage of 550,000 gallons daily. The disposal works consist of 3 septic beds and 12 bacteria beds. When treated the effluent is discharged into the lake.

From the foregoing description of the alterations designed and in progress it will be gathered that in the course of a few years the city should have a satisfactory system of sewage disposal.

By the courtesy of Mr. Charles H. Rust, city engineer of Toronto, and of Mr. A. C. D. Blanchard, assistant engineer in charge of the drainage department, I was afforded every facility for acquiring information with respect to the sewerage system of Toronto.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The University.

THE annual dinner of the past and present students of the Medical School was held at the Grand Hotel on Nov. 25th. Professor J. T. J. Morrison presided. After the toast of "The King" had been honoured, Mr. Charters J. Symonds, senior surgeon to Guy's Hospital, proposed that of "The Medical School." Professor H. Gilbert Barling, Dean of the Medical Faculty, in responding, referred to the many changes which had occurred in the staff, and especially to the death of Dr. A. Foxwell and the appointment of Professor A. Robinson to the chair of anatomy at Edinburgh. Dr. O. J. Kauffmann, senior physician to Queen's Hospital, proposed the toast of "The Guests," and this was responded to by Sir James Barr and Professor Peter Thompson, the newly appointed professor of anatomy. Musical items we rendered by Mr. B. A. Lloyd, Dr. Walsh, and Dr. Aitken. Musical items were

The Huxley Lecture.

This lecture, which is open to the public as well as to friends of the University, is delivered annually by an eminent investigator in biological science. This year Professor Bateson, F.R.S., gave a masterly exposition of "Mendelian Heredity," a subject peculiarly appropriate for a Huxley lecture.

Priestley Relies.

A valuable collection of Priestley relics has been presented to the University library. They have been continuously in the hands of the Priestley family, and the donor is Miss S. P. Wainwright, a great-great-granddaughter of the discoverer of oxygen. The gift includes about 70 books from Priestley's own library and bearing his book-plate, most of them being volumes of his own works. Among them may be noted "The History and Present State of Electricity, with Original Experiments by Joseph Priestley," published in 1767 and dedicated to the Earl of Morton, P.R.S., and "The History and Present State of Discoveries Relating to Vision, Light, and Colours," dedicated to the Duke of Northumberland and published in 1772.

The Hospitals of Birmingham.

A special course of lectures on Birmingham institutions is being given in the University under the auspices of the Workers' Educational Association. On Nov. 25th Alderman Lloyd lectured upon "The Hospitals of Birmingham," the chair being occupied by Professor Priestley Smith. oldest institution is the General Hospital, promoted by Dr. Ash in 1765 and opened with 40 beds in 1779. expenditure on hospitals now amounts to £96,125 a year. Much attention was paid by the lecturer to the right use of hospitals and the possibility of rate aid at some future time.

Birmingham Medical Mission.

The thirty-fourth annual report of this institution shows that 7413 cases were treated in the past year, in respect of

of the institution, medical, evangelical, and social, is carried on at an expenditure of less than £1300.

Guest Hospital, Dudley.

At the annual meeting of subscribers to this hospital it was stated that, having regard to the improved financial position of the hospital owing to the munificent bequest of the late Mr. Hugh Lewis, the committee felt that greater completeness and efficiency should be aimed at, and the following improvements were recommended: (1) the reconstruction of the lavatories and bathrooms in the men's wards; (2) a new detached building for surgical and ophthalmic outpatients, and possibly a dental department; and (3) a new boiler for the laundry and supply of hot water to the hospital. An enlargement of the children's ward is under consideration

Crick District Council and the Medical Officer of Health.

The medical officer of health for the various councils comprised in the Mid-Warwickshire joint sanitary district has officiated in that capacity for the Crick rural district council. Owing to the withdrawal of Yardley from the combination, and the resignation of Mr. A. H. Wilson, the Crick council has to make a fresh appointment. The Local Government Board urge the appointment of a whole time medical officer by the mid-Warwickshire joint sanitary committee. There is, however, a strong feeling in the district in favour of the appointment of a local practitioner, and the council has written to the Local Government Board asking if it would continue as now to pay half the salary of a local man.

Dec. 6th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Hospital Sunday.

THE collections on Hospital Sunday do not do credit to any claims to, or assumptions of, philanthropy that Manchester may put forward. This must be said, even after allowances have been made for the fact that many of the wellto-do live out of town and that the churches and chapels may also suffer from "the week-end" habit. It would be so very easy for those who live away, and those who go away, to arrange that their contributions (which they would have been so delighted to add to the collections, only unfortunately they were out of town) should be given by proxy that it is quite unaccountable that that little arrangement was not carried out. In the meantime the old custom holds that the few, those whose names are to be found among the subscribers to most of our institutions, are supporting the hospitals rather than the many. The many may not be able individually to give much, but if they gave a little, just what they could well afford, there would be a rich harvest for the hospitals. At the annual meeting the other day the Lord Mavor (Mr. Charles Behrens) said he was thoroughly dis-satisfied with the result of the fund, and also with the cost of its working—over £200 to collect £3600. He said that during his year of office he intended to do all he could to make the fund more effective. He should be extremely sorry to see the municipalisation of charitable institutions as he believed they could be managed more economically and sympathetically by voluntary workers. The Mayor of Salford (Alderman Snape) agreed with the Lord Mayor that the sum was beggarly, and suggested that there should be a small committee in connexion with every church where the collections were made. The treasurer said he had been distressed about the fund for many years. The Dean (Bishop Welldon) questioned whether February was the best time of the year to make the collections, as many others have done before him. He spoke somewhat severely about the insufficient sense of public duty on the part of influential citizens, some of the richest of whom did not discharge their public duty at all, and "the only reason that he should desire that the hospitals should come on the rates was so that these citizens should not escape the burden of their upkeep altogether. It remains to be seen whether the people of Manchester and Salford will be persuaded or shamed into an increased sense of their duties to those less fortunate than themselves.

Treatment of Canoer.

At the annual meeting of the Manchester Christie Hoswhich 32,421 attendances had been made. The whole work pital (Cancer Pavilion and Home), which was held on

Dec. 3rd, some interesting work was reported. During the last year 110 in-patients and 68 out-patients were treated, as against a total of 156 in the previous year. Of the 93 new cases, 37 were males and 56 were females; 9 of them were recurrent after previous operations when first admitted to the hospital. During the past year a permanent abode was provided for 63 patients who could not be properly treated at home. All of them were admitted in an advanced stage of the disease, too late to allow of any chance of very much benefit, to say nothing of cure, but with the hope of alleviating suffering as much as possible during the remainder of their lives. All died in the hospital, and so the death-rate is much higher than that of any general hospital. The Lord Mayor, who was in the chair, and Sir Edward Donner, in moving and seconding the adoption of the report, spoke feelingly on the subject of cancer, and the former said, "the only consolation was that the whole medical profession was bent on the discovery of the causes of, and the cure for, cancer," while the latter paid a well-merited tribute " to the matron and nurses who took charge of the cases, which must often be of an extremely trying nature." Professor R. B. Wild made some valuable observations on cancer research, and "wished that the other hospitals in Manchester would join in inaugurating a fund for the purpose of coordinating research as to cancer, because he believed that in that way only could they obtain any real value from the study of cases of cancer." During the last 17 years they had tried every method of treatment that had a reasonable basis of probability that it might do good, some 20 or 30 methods, without the anticipations of the inventors being realised, but they had gained much experience of the utmost value for the relief of patients and the prolongation of their lives. He thought that if there were a committee to coordinate the work they would obtain more valuable information than by simply looking at one aspect brought out by one hospital. Professor G. A. Wright thought that it would be better to have a research centre in Manchester than to trust to the work done elsewhere. As regards the hospital, they wanted to assure people that cancer was not always hopeless if advice was taken in the early stages. Of course, with cancer, as with "consumption," delay is fatal, but there is the great difficulty that the patients are for a long time unaware of their danger. Professor Wright spoke also of the danger from "quacks." He knew of one scoundrel, living not far from them, he said, who let a woman with nothing more than a wart on the tongue go about with a bottle of "cancer lotion," and of course live in dread of cancer. "They had to get people to realise the folly of dealing with quacks. The cruelty of quacks and the speculative hopes that lead so many to trust in the divine inspiration of anyone who is called an irregular practitioner are mutually supporting.

The Fight Against Tuberoulosis.

The question of the best way of dealing with tuberculosis among the poor becomes more and more pressing. Boards of guardians are in great difficulties, for in many unions the numbers to be dealt with are alarmingly great. The matter recently came under discussion at a special meeting of the Chorlton board. As always, the special difficulty was the late period at which most of the cases come under observation and treatment. In the Withington Hospital 300 or 400 cases are admitted every year, of whom not more than 12 or 15 are fit to go to sanatoriums. There is no power of detention, and many hopeful cases, driven by the need to work, leave prematurely. At present the board has 11 patients in sanatoriums at a cost of £1100 a year, and the Manchester corporation pays £2000 a year for 20 beds at the Delamere Sanatorium. These numbers, however, are but as a drop in the bucket, as the chairman said. Where the head of the family is ill with phthisis, his wife and children cannot be allowed to starve, so that it is easy to understand the enormous expense involved in even the most economical methods of dealing with this scourge. The medical officers of the union were present and agreed generally that when first seen the cases were, as a rule, too far gone for sanatorium treatment, but if it were known that it was available there would be many applications. Dr. J. S. Orchard, who had been for many years resident at Withington Hospital, was not very sanguine as to the permanent effect of sanatorium treatment, for though the patients were practically well while in the sanacorium, "after six months of hard work and insufficient food

in unhealthy surroundings they relapsed." In the end it was decided to ask the Manchester board to join the Choriton board in approaching the health department of the Manchester corporation and request it to provide sanatorium accommodation for consumptives. This is a formidable but a very desirable undertaking. It shows how severe the struggle must be if consumption is to be banished from our midst.

Dec. 7th.

WALES.

(FROM OUR OWN CORRESPONDENT.)

Housing in Wales.

The reports which have been issued in recent years, not only of the medical inspectors of the Local Government Board but also of the district medical officers of health, have revealed conditions of housing in various parts of Wales which can only be described as deplorable. In no part of the kingdom is there greater need for efficient administration of those Acts of Parliament which refer to the housing of the working-classes, but it is to be feared that the sanitary authorities whose duty it is to initiate reforms will not be stirred to activity unless the pressure of public opinion is brought to bear upon them. A first step towards the concentration of that opinion has been taken in the formation of a Welsh Housing Association for the purpose of investigating the facts relating to housing conditions in Wales and for bringing within reach of the people the means of reform upon the most modern lines.

School Dentistry in Cardiff.

Arrangements have been made with eight dentists in Cardiff to attend to the teeth of the children attending the public elementary schools upon the same terms upon which they attend members of the Provident Dispensary. The education committee will thus pay them 6d. for each tooth extraction and 2s. for each stopping.

Collicry Surgeons in South Wales.

Although for the most part the relations between the colliery surgeons and the workmen employed in the South Wales collieries are of a satisfactory character there are instances here and there where some change is desired either by the men or the surgeons. At a meeting of miners held in the Rhondda valleys on Nov. 29th it was stated that a ballot of the men had decided in favour of the establishment of medical committees, by whom the colliery surgeons should be appointed and under whose supervision they should be placed. Those who have watched the development of the colliery districts during the past 25 years cannot fail to have noticed the admirable manner in which Mr. W. Abraham, M P. (Mabon), has used his influence with the workmen when conflicts with the masters have been imminent, and it cannot be denied that disputes between the surgeons and the men would have been of much greater frequency had it not been for the restraining influence which he has been able to exercise at the proper moment.

Damages against a Dairy Farmer.

An action lasting nearly four days has been tried at the Liverpool Assizes in which the proprietor of a boys' school near Conway claimed damages against the executors of a dairy farmer on the ground that typhoid fever had been introduced into the school through the agency of the milk supplied from the farm. The farmer's housekeeper and her daughter had been attacked with the disease and he himself subsequently died from it. The outbreak at the school began early in April about a fortnight after the housekeeper had returned to the farm from the isolation hospital. Several of the poys were attacked and later the schoolmaster, his daughter, and wife were infected, the illness of the last terminating fatally. Cases occurred in other houses besides the school where milk was supplied from the same farm, altogether about 24 cases being reported. was some conflict of evidence as to the cause of the school outbreak. Sir James Barr and Dr. Meredith Young maintaining that it was due to the milk-supply, while Mr. A. G. R. Foulerton, Dr. T. R. Glynn, and Dr. Nathan Raw contended that the milk was not responsible and that the primary cases became infected indirectly through the condition of the foreshore of the river Conway. In the course

of the evidence it transpired that the proprietor of the school had taken the precaution to obtain a certificate to the effect that the drainage of his house had been found after examination to be in a satisfactory condition. He had also secured a favourable report as to the water-supply of his own house and as to the sanitary condition of the dairy farm. When summing up Mr. Justice Bray stated that there was an implied warranty that the milk supplied to the school was reasonably fit for consumption. The jury gave a verdict in favour of the schoolmaster, and assessed the damages at £500.

Dec. 6th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

An Edinburgh Cremation Society.

Dr. W. G. Aitchison Robertson, who has been a consistent advocate of cremation in Scotland, on Dec. 3rd delivered a lecture in the Goold Hall, Edinburgh, in which he expounded the sentimental, sanitary, and economical advantages of disposing of the dead by cremation and the corresponding disadvantages attaching to earth burial. He was followed with attention and at the close of his address a resolution was passed unanimously to the effect that an Edinburgh Cremation Society be formed to promote the practice of cremation. A committee has been already appointed to adopt a constitution and elect officers for the society.

High Death-rate in Glasgow.

The five continuous days of dense fog which prevailed in Glasgow in the third week of November are apparently responsible for the great increase in the death-rate. For the week ending Nov. 13th the death-rate was 18.0, and for the next week, during which fog constantly prevailed, 24.9 per 1000. This latter rate is greatly in excess of the average, which is 17.5 for the fourth quarter of the year. The number of deaths of infants under one year rose from 106 to 149, of children under five years from 191 to 279, and of persons over 60 years from 118 to 150. As is to be expected, the largest increases occurred in deaths attributable to the various forms of lung disease, and the rate from these diseases rose from 4 to almost 8 per 1000. The number of deaths from all causes, which had been 283 in the first week, was 395 in the second. Deaths attributable to acute disease of the lungs, which had been 82 in the first week, were 134 in the second week; deaths from consumption increased from 16 to 31, and from measles, which most commonly proved fatal through lung complications, from 20

Railway Conveyance of Milk.

The public health committee of the Glasgow corporation has been in touch with the various railway companies as to the question of allowing milk-churns and milk-butts to be sealed so as to prevent unauthorised persons at the stations or in the course of transit opening the lids of the churns or taking the cocks out of the milk-butts, thereby causing contamination. The subject was discussed before a meeting of the associated railway companies, but they declined to concur in the proposal. They were of opinion that the seals would be very liable to be broken in the ordinary course of transit, and, further, that under the conditions of the form of Milk Risk Note signed by the senders of milk traffic the officials of the companies had power to open any cans during transit in order to ascertain if the quantity of milk therein agreed with the quantity declared.

Addition to the Western Infirmary, Glasgow.

At the thirty-fifth annual meeting of qualified contributors to this infirmary held last week one particularly gratifying feature in the report submitted was the progress that is being made in bringing the hospital still more up to date, both as regards accommodation and appliances. A new pavilion to hold 90 beds is in course of construction. Also, through the generosity of a donor who wishes to remain anonymous, a sum of £5000 has been received for the erection and equipment of a clinical laboratory, which should prove a very desirable adjunct to the medical school, and also of great use in the diagnosis and treatment of disease. Also, it is worthy of note that the Provisional Order promoted by the directors of the Skin Hospital has received the Royal Assent,

and the work carried on by that hospital for so many years is now being carried on in the dispensary of the Western Infirmary.

Death of Dr. James Stevenson, Clydebank.

One of the best known and most highly respected residents in Clydebank passed away last week in the person of Dr. James Stevenson. He had been ailing for some time but was still able to go about, and his death in the end occurred somewhat suddenly. Born in Dunfermline 58 years ago, he was at first apprenticed to a trade, but by his own energy and perseverance he entered the University of Glasgow, where he graduated M.B., C.M. It is some 30 years ago since he went to the district which is now Clydebank, just about the time when it began to be a great shipbuilding centre. As the place grew he acquired an extensive practice, which he worked almost to the end. He was medical officer for the burgh and for the central portion of the parish of Old Kilpatrick. He took an active part in public life. Elected to the school board, he was chairman for a term, and at the time of his death he was a county councillor for Dumbartonshire. He leaves a widow and family including two sons who are members of the medical profession.

University of St. Andrews: 500th Anniversary.

The general committee which has in hand the arrangements for a fitting celebration of the 500th anniversary of St. Andrews University held its first meeting on Nov. 27th within the hall of the United College. After a few opening remarks by the Principal, Professor Lawson, convener of the provisional committee, gave an account of its work. It was resolved that the President should be the Chancellor, Lord Balfour of Burleigh. Subcommittees of the general committee were also constituted. On the motion of Professor Herkless it was agreed that the celebrations should take place in September, 1911, having in view the fact that Bishop Wardlaw had recognised the existence of a University of St. Andrews in 1411. On the question of a permanent memorial of the celebration, it was suggested that this should take the form of a new students' union. It was resolved to refer this, as all proposals dealing with this question, to the convener's committee.

Sidlaro Sanatorium : Financial Position.

In connexion with the Sidlaw Sanatorium financial crisis a public meeting was held on Dec. 3rd in the Burgh Court Room, Dundee. Fully an hour's discussion took place, when all the facts were disclosed, and in the end the Lord Provost, who presided, undertook to lay before the town council a modified scheme of municipalisation, while a committee was appointed to make a systematic canvass for subscriptions to support the institution in the meantime.

Infantile Mortality in Inverness and Elgin.

The public health committee of the Inverness town council at a meeting on Nov. 29th discussed at length the Notification of Births Act. In the course of the discussion it was stated that Inverness was one of the few burghs in Scotland with a very high death-rate among infants. It was eventually agreed by 7 votes to 2 to recommend the council to adopt the Act. The Elgin town council met on the same day in order to discuss what might be done in order to lessen the high rate of infant mortality in the town. It was decided to appoint a third nurse for Elgin to advise mothers and assist in nursing their children.

Dec. 7th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Health, Food, and Cookery.

ONE of the most significant features of the hygienic advancement which has been secured for this country by the efforts of the Women's National Health Association was displayed to the public eye by the recent Irish Food and Cookery Exhibition at the Rotunda. The exhibition had been organised by the Hotel and Tourist Association of Ireland, and the ceremony of declaring it open to the public was carried out by the Countess of Aberdeen, who said that the relection of proper food and the right preparation of it had a very great effect upon the national health and character. The inevitable effects which must

result from a deficiency of proper food for the infant members of the community—of a want of proper, clean, healthy milk, or the defective qualities of that of the mother which necessarily resulted from insufficient nourishment-were also pointed out by the speaker, and also the fact that from that cause alone arose very much of the bad health and the bad temper with which they had to deal from time to time, while it was also productive of great collective loss to the nation. An exhibition of that kind, by drawing attention to the importance of food from every point of view, must help to secure the health of the nation by building up the health of the home. Considerable applause was elicited by Her Excellency's statement that: "Owing to the exertions of the Women's Health Association the children in various parts of the country were now always asking for stirabout. All medical readers will admit that no more appropriate sequel to the Tuberculosis Exhibition could be provided than a Cookery Exhibition. Bad air was treated at full length by the former; bad food will be thoroughly exposed by the latter; while bad drink is being deliberately and unsparingly dealt with by the leaders of the present temperance crusade. These are the true "grievances" of the home life of the Irish poor, and this fact makes the present position all the more auspicious.

The Dublin Milk-supply.

It is hopeful to see that our corporation has recently been waking up to the importance of the supply of pure milk in Dublin, seeing that the tenement room and the milk van are chiefly responsible for the preparation of the soil most suitable for the germs of crime and insanity, and when moistened by stimulating beverages and continuously tended by bad company the yield of its harvest may be calculated on with confidence. On one day last week in one of the Dublin police courts a dairyman was fined £2 for selling margarine, of which the label was not clearly visible to the purchaser; a dairy-keeper was fined £5 for the sale of milk adulterated with 16 per cent. of added water; and another £3 for the sale of milk containing 10 per cent. of added water. Such records, which are repeating themselves every week in the Irish metropolis, display a condition of mercantile morality which can only be dealt with effectively by the most stringent measures, and it is encouraging to find the Recorder has thrown all his influence into the scale in the weighing of this question-a step which has also been followed by our police-court magistrates.

Rathmines Urban Council.

At the meeting of the urban district council of Rathmines which was held last week the report of the Local Government Board auditor was read, with the enclosed certified abstracts of the accounts of the council for the year ending March 31st, 1909. The general receipts amounted to £56.334 18x. 2d., and the poor rate receipts to £29,663 1s., making a total of revenue receipts of £85,997 19s. 2d. The sum expended on private works had amounted to £1259 16s. 2d., and the surplus, which represented the accumulation of some years. having been added to the general fund, a balance of £918 0s. 10d. was left for the carrying out of other works under the same headings. The medical officer's report for the five weeks ending Oct. 30th stated that the total birthrate was 15.9 per 1000, while the total death-rate had been 10.9. During the same period the total annual death-rate in 33 of the largest English towns was 12.3 (that of London being 11.8); in eight of the largest Scotch towns, 12.8; in 23 of the largest towns of Ireland, 15.5—in Dublin, 18.1; Clontarf and Howth (No. 1 district), 15.7; Donnybrook, 12.1; Blackrock, 20.3; and Kingstown, 13.0.

The Public Health of Belfast.

At the monthly meeting of the corporation of the city of Belfast held on Dec. 1st it was reported that the Tuberculosis (Ireland) Prevention Act came into operation on Nov. 1st, and that during the three weeks following 102 cases had been reported. The death-rate from all causes for the four weeks ended Nov. 20th was 16.7, while it was 5.9 from chest diseases and 1.1 from zymotic affections. The number of cases of infectious diseases notified is greater than in the preceding month, but less than in the corresponding period of the previous year. Great objection was expressed at the action of the Local Government Board in refusing to give the corporation the necessary powers to supervise outside dairies for the reason that the Act was a comparatively new one, and that outside authorities should,

they said, get a chance of seeing to the condition of things. Owing to this action of the Local Government Board in reference to the largest city in Ireland (where two-thirds of the milk-supply comes from outside sources), it has been decided by the Belfast local authorities to instruct their medical officer of health to prepare for the information of the public health committee a list of the dairies outside the city from which milk is supplied for consumption inside the city, distinguishing those who permit an inspection of their premises and those who do not. Permission was given at the meeting of the Belfast city council on Dec. 1st to bring in a scheme for clearing away the insanitary areas of the city which could not be dealt with in any other way, and it appears that in all 1159 houses will be affected and about 3000 to 4000 persons will be unhoused. It was also intended to widen streets which were at present narrow, to open out streets which were not thoroughfares, to allocate portions of grounds for open spaces, and to utilise some as playgrounds for schools. The scheme is valued to cost about £90,000, and in addition £20,000 for model buildings to replace those removed. The scheme will not go through until there is a sworn inquiry into its provisions by the Local Government Board. A special meeting of the council is to be called shortly to consider the whole matter. Dec. 7th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Alleged Immunity of Arabs to Enterio Fever.

It is a generally accepted view that Arabs possess a considerable degree of immunity to typhoid fever, and that when persons who have lived in France proceed to Algeria they are attacked by the disease about 100 times more readily than the Arab natives. M. Moty, M. Toussaint, and M. Billet called attention to this subject at a recent meeting of the French Society of Military Medicine when M. Billet did not accept the above-mentioned view. He said that this immunity was merely relative, and he quoted several cases in support of his opinion. He remarked that conclusive evidence in this respect was supplied by an epidemic which broke out at Sfax in 1899, for among 32 cases of typhoid fever occurring in the garrison there were 22 native patients-i.e., a proportion of 68 per cent. The infection was brought into the garrison by the natives, and the 11 first patients were native tirailleurs who were enrolled as volunteers and had been in the army only a few days. It was therefore unquestionable that Arabs might be attacked by typhoid fever in certain circumstances which were as yet rather obscure. The cases were generally severe and their real nature was often misunderstood; the seizures might be sudden and violent and were then liable to be mistaken for pernicious forms of malaria.

Adulteration and Fraudulent Misdescription of Food and Beverages.

In his report on agricultural finance M. Noulens has dealt at considerable length with the prevention of various kinds of fraud in connexion with the preparation of food and beverages. In one year the officials employed in this work have been increased from 931 to 1068. During the year 1908 there were 67,726 samples examined, of which 14.4 per cent. were unsatisfactory. Samples of all kinds of beverages and food products were taken indiscriminately and usually at random. At the commencement of this preventive work it was found that oil, milk, vinegar, and wine were the articles most liable to be tampered with. The average for the year 1907, which showed 20 per cent. of unsatisfactory samples, was reduced in 1908 to 14.4 per cent. and in the beginning of 1909 to 14.1 per cent. Frauds in connexion with mineral waters have become exceptionally prevalent of late years, both in the actual factories which supply retailers and also in a great many restaurants. Samples of mineral water were not collected for analysis until the end of 1907, when it was found that a restaurant was selling common water in bottles labelled Evian-Cachat. In 1908 many restaurant keepers were detected selling ordinary water as the produce of well-known mineral springs (Evian, Vittel, Baudoit). Visits were paid to wholesale dealers, and four important seizures were made on the premises of persons who manufactured spurious mineral waters chiefly by the use of bicarbonate of sodium.

Baoteria on Fruit.

M. Sartory and M. Fillassier have been making bacteriological examination of fruit exposed for sale in shops open to the street and also in costermongers' barrows and baskets. The fruit consisted of grapes, strawberries, red currants, and cherries. In giving an account of their results at a meeting of the Biological Society they said that the sterilised water in which the fruit received its first washing was afterwards found to contain staphylococcus, streptococcus, bacillus termo, bacillus subtilis, and micrococcus candicans, the number of organisms varying according to the condition of the fruit as regards cleanliness from 68,000 to 3,200,000 per cubic centimetre. On the second washing these numbers ranged from 7000 to 120,000, and on the third washing they ranged from 3000 to 27,000.

Prophylaxis of Typhoid Fever.

At a meeting of the Academy of Medicine held on Nov. 16th, M. Delorme continued a discussion in the previous portion of which M. Vincent, professor at Val de Grace, had mentioned a number of ways in which typhoid fever might be propagated. M. Delorme said that in his opinion the quality of the drinking water was the point on which sanitarians ought to concentrate their attention. It was by providing an abundant supply of good water that municipalities which were desirous of improving the health of their towns put an end to epidemics of typhoid fever. Much still remained to be done in this respect, especially in certain districts of the east and south of France. Even in garrison towns where the barracks had a good water-supply provided at great expense the town's supply was unsatisfactory, and soldiers who drank it during their visits to places where liquor was sold afterwards suffered from typhoid fever. It would be remembered that an outcry was raised not long ago because in a garrison town where typhoid fever was prevalent the military authorities wished to forbid soldiers resorting to refreshment houses the water-supply of which was derived from notoriously polluted wells. He was not without fear lest the establishment of laboratories and systematic inspection and the publication of pamphlets would tend to give municipalities an excuse for not proceeding with the only true prophylactic measure, the providing of an abundant supply of good water with supervision of the sources. An army medical officer in a garrison town was in some respects more favourably placed than a laboratory specialist, because he witnessed the earliest stage of an epidemic, he could investigate the causes which led to it, he was acquainted with the local conditions, and he could suggest measures for preventing its extension and its possible recurrence in the future.

Anti-tuberoulous Vaccination of Cattle.

After investigations extending over many years Professor Arloing, director of the Veterinary School of Lyons, has discovered, he says, a method of vaccination for the protection of cattle from tuberculosis. The vaccines which he employs are derived from definite kinds of bovine bacilli; they are obtained by a special process of culture, and are capable of unlimited transmission. These modified bacilli cause no appreciable lesions, and the treatment cannot injure the cattle. The vaccination may be either intravenous, subcutaneous, or by way of the alimentary canal. travenous method has given the best results -namely, 75 per cent. of successful cases, and introduction by way of the alimentary canal came next with 50 per cent. of successful Professor Arloing says that improvements in the details of the method may be expected, but the results already attained warrant its employment, together with ordinary prophylactic measures, for the prevention of bovine tuberculosis. At a meeting of the Academy of Sciences held on Nov. 29th Professor Chauveau said that he had been able to corroborate the conclusions at which Professor Arloing had arrived.

Dec. 7th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The late Duke Carl Theodor of Bavaria.

H.R.H. Duke Carl Theodor of Bavaria, M.D., died at his country seat at Kreuth in Upper Bavaria on Nov. 29th. The members of reigning families in Germany or elsewhere. As a syphilis. He mentioned that by the Wassermann reaction

youth he entered on a military career like the majority of other princes, but exchanged it for more congenial pursuits -namely, the study first of philosophy and afterwards of natural science and of medicine. In 1872, on the occasion of the fourth centenary of the University of Munich the honorary degree of M.D. was conferred on him. He now became greatly interested in diseases of the eyes and worked at this specialty under the late Professor Rothmund of Munich and Professor Arlt of Vienna. In 1880, having passed the State examination and thereby become qualified as a medical man, he not only commenced practice in Munich as an ophthalmic surgeon, but also established private clinics in Munich and Tegernsee, where he used to reside during the summer. A dexterous operator, he very soon acquired, both in his own country and abroad, such a reputation for surgical skill that his practice in diseases of the eye was one of the largest in Germany. His patients for the most part belonged to the poorer classes as he never charged fees, but he was also consulted by well-to-do people and especially by the royal personages who were his relatives and friends. It may be remembered that when the present Emperor of Germany suffered a few years ago from an injury to one of his eyes caused by an accident he consulted the late duke, who came from his residence at Munich to the port of Kiel where the accident had happened. The number of the operations performed by him especially for cataract was enormous; in fact, he was in this respect surpassed by only a very few Notwithsurgeons in the same department of practice. standing his exalted rank and social position he identified himself with the interests of the rank and file of the profession, loyally cooperating in whatever steps had to be taken for the assertion of their privileges and for the reform of abuses connected with the existing legislation on sick-clubs. According to the Voss-Zeitung, he was a member of the Munich Free Choice Society and willingly acquiesced in the control of club practice exercised by the committee of this society. He was also one of the early members of the great medical union, known as the Leipziger Verband, to which allusion has been repeatedly made in these columns. The late duke was the author of numerous works in several branches of medicine. His first contribution was published as early as 1871 in the Zeitschrift für Biologie and dealt with the influence of the atmosphere on the metabolism of respiration; in 1877 he wrote an account of experiments on the accumulation of leucocytes in the cortex of the brain, and in the following year he published microscopical researches in certain diseases of the spine. His first work in diseases of the eye was devoted to the anatomy and pathology of the vitreous humour; in 1882 he wrote an essay on myopia from an anatomical point of view; and in 1887 one on the pathological condition of the eyes in diseases of the kidney. For the annual reports of the Munich municipal hospital he contributed an essay on growths of the orbit, and for the Festschrift on the occasion the seventieth birthday of the late Professor Helmholtz, he wrote a description of a case of callosity of the superior evelid. Duke Carl Theodor was born in 1839, his father being Duke Maximilian of Bavaria. He was twice married, his first wife being the Princess Sophia of Saxony who died in 1867, and his second the Princess Maria Josefa of Portugal, who took an active part as an assistant in her husband's clinical work. Of his sisters two came by their death in very tragic circumstances-namely, the Empress Elizabeth of Austria, who was murdered at Geneva by an Italian anarchist, and the Duchess of Alencon, who perished. together with so many other French notabilities, at the great fire at the Bazar de Charité in Paris. The death of Duke Carl Theodor has caused great sorrow everywhere, especially among the dwellers in the Bavarian Alps, where he had his favourite residence. At Possenhofen he had a model farm, and he was much interested in the retention of their picturesque national costume by the Bavarian peasants, giving prizes to families who conformed to his ideals in this respect. It may here be mentioned that another member of the Bavarian royal family, Prince Louis Ferdinand, a cousin of the late duke, is a qualified medical man too, but does not practise. Idiooy and Syphilis.

Dr. Lippmann, an assistant to Professor Wassermann, has published in the Munich Medicinische Woohenschrift an

syphilis has recently been ascertained to be one of the causes of progressive paralysis, and the existence of a similar connexion between idiocy and syphilis has been suggested by various clinicians, the estimates varying from 11 to 23 per cent. Dr. Lippmann has applied the Wassermann reaction to idiots in two asylums—the provincial asylum of Uchtspringe in Westphalia for children of the rural population and the asylum of Dalldorf, which belongs to the city of Berlin, and therefore has for its inmates children coming from an urban population. As a control he first used the Wassermann reaction for a series of epileptic children, and found it to be positive only in a few instances in which the patients also showed other symptoms of syphilis. Of 78 idiots in the Uchtspringe asylum the reaction was positive in seven (i.e., 9 per cent.), but among the idiots in the Dalldorf asylum it was positive in 13 2 per cent. By examination of the patients and by the anamnesis Dr. Lippmann, however, found syphilitic symptoms in about 40 per cent. of the idiots, so that there is probably some connexion between syphilis and idiocy. He alluded to the researches of Dr. Baisch, who found in lying in hospitals that in syphilitic women the disease is latent in about 75 per cent. of the cases, the Wassermann reaction being positive and spirochetæ being present in the placenta, but the woman not showing manifest symptoms of the disease. He therefore recommended the use of serum diagnosis in lying-in hospitals for the purpose of disclosing latent syphilis. The children born of mothers who gave a positive reaction should, if necessary, be subjected to antisyphilitic treatment. He further suggests that this method of diagnosis might be advantageously given an extended trial in cases of idiocv. Dec. 6th.

NOTES FROM INDIA. (FROM OUR OWN CORRESPONDENTS.)

Piague.

For the week ending Oct. 30th plague seizures and deaths throughout India numbered 4287 and 3456 respectively. The mortality in the different provinces was as follows: Bombay Presidency, 946: Madras Presidency, 94; Bengal, 53; the United Provinces, 634; the Punjab, 476; Burma, 14; the Central Provinces, 837; Mysore State, 166; Central India, 212. The figures for Rajputana have not been received. Nagpur city reported 561 deaths.

Malarial Fevers and the People.

The interesting and suggestive paper by Sir Herbert Risley in which he summed up the work and results of the Malaria Conference at Simla is especially worthy of attention, because it was written with the object of inviting popular cooperation in the prevention of malaria. He truly says that to combat effectively this ancient, widespread, and destructive scourge is a task which cannot be accomplished by any official machinery that can be devised or even contemplated. The cost of the huge cofficial machinery which would be required would be prohibitive. Secondly, every rupee spent on the official staffs would be so much less available for the actual measures needed to cope with the disease. And, finally, the various operations which must be carried out to remove conditions productive of malaria would possibly and even probably rouse hostility unless they were so explained as to convince the people that they were intended for the benefit of the community. We may go further and affirm that these processes will never be thoroughly worked until they become as much a portion of the routine of village life as the healthful daily bath, which is properly considered one of the most wonderful institutions in India. The cooperation of the people is therefore absolutely necessary. Can it be secured?

The Proposed Research Institute for Maymyo.

The Secretary of State has declined to sanction the scheme for establishing a research institute in Maymyo, of which the Pasteur Institute was to form a part. The ground for his refusal is that in the present state of provincial finances it is inadvisable to embark on an ambitious undertaking of this description, and with this cautious policy few

will be disposed to cavil, seeing that the estimated expenditure on building alone was close on 6 lakhs of rupees.

Health of the United Provinces.

The sanitary report of the United Provinces for 1908 deals largely with "the deplorable epidemic of malarial fever which swept through the greater portion of the provinces between August and September." The mortality was the highest ever recorded: about one-twenty-fifth of the whole population perished from "fever," while the deaths from all causes amounted to 2,514,767, or one-twentieth of the population. At the same time the birth-rate fell from 41.18 to 37.46 per 1000. Apart from malaria, the year, despite famine conditions, was by no means abnormally unhealthy. It is a noticeable feature of the malarial epidemic that the districts where famine was worst were not, as a rule, severely attacked by malaria, but where it appeared it attacked all classes of the population alike-rich and poor, Europeans and Indians. In the four months from September to December the fever death-rate was 23 92 per 1000, as compared with an average of 10 71. Quinine was distributed in far larger quantities than in any previous year, much of it being given free of cost, and excellent results are reported to have been achieved; but there are, of course, great difficulties in the way of placing sufficient quantities of quinine to check an epidemic within reach of the mass of the people. The question of improving the system of distribution of quinine is now under consideration, and a special inquiry is being conducted by Major J. C. Robertson, I.M.S. There was excessive mortality among infants owing to malaria, famine conditions, small-pox, and measles. with the general population the infant mortality was the highest ever recorded, and reached the appalling figure of 345 · 1 per 1000, so that one infant perished out of every three born. This question of infant mortality has been receiving serious attention, and an inquiry into its causes is being commenced at Cawnpore by a lady doctor assisted by two trained midwives. Despite unfavourable financial conditions the year was one of much activity in sanitary matters. There was a sanitary conference in September, and the recommendations made at it. many of which have been approved and are being carried into effect, will, it is hoped, improve the sanitary conditions of towns and villages. municipalities, having been relieved of police charges, are now able to devote over 5 lakhs per annum, formerly spent on the police, to sanitary and other improvements, and these additional resources should enable many necessary works to be carried out.

A New Hospital for Meerut.

The Lieutenant-Governor of the United Provinces (Sir John Hewett) laid the foundation-stone of a new general hospital at Meerut on Oct. 29th. At a durbar held so recently as February last his honour mentioned that the existing General Hospital at Meerut has inadequate accommodation and indifferent equipment, and that the female hospital, although its buildings are modern, stands on a most unsuitable site. The Lieutenant-Governor complimented Meerut residents upon the public spirit and alacrity with which they had taken action on his remarks, for in so short a time the large sum of Rs.77,000 has been collected in subscriptions towards the cost of the new buildings. In addition to these voluntary contributions, Rs. 30,000 have been provided by local bodies and Rs. 63,000 will be realised by the sale of the sites of the old buildings, a sum of R: 1,70,000 having, therefore, been secured by local effort towards the total of Rs.2,15,000 required for the buildings. As a substantial proof of the sincerity of his compliments and on the principle that the Government should readily help those who help themselves, Sir John Hewett promised the Rs. 45,000 balance of the cost. thus redeeming a promise he made in March last to the people of Meerut. He congratulated those responsible on the excellence of the proposed buildings, and hoped that their equipment would be made sufficient and the wards bright and comfortable. With characteristic thoughtfulness he suggested that the hospital should be named the "Ludovic Porter" Hospital, to commemorate the interest which the Collector of Meerut has taken in the project, as well as in all other schemes for the benefit of the city and district.

Nov. 10th.

Gbituary.

ROBERT MARCUS GUNN, M.A., M.B., C.M. EDIN., F.R.C.S. ENG.,

SENIOR SURGEON, ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS, ETC.

Robert Marcus Gann, whose loss we have to deplore, came of an old Scandinavian stock settled for many generations in the north and north-east of Scotland. He was born at Culgower in Sutherlandshire in 1850, the youngest of a family of four, consisting of two sons and two daughters, none of whom survive him. Educated for a year at his native village school, and afterwards at a larger school in Golspie, he went at the age of 14 to Edinburgh, where later he graduated with distinction, taking the M.A. in 1871 and the M.B. and C.M. in 1873. He was contemporary there with Robert Louis Stevenson, whom he knew slightly. His teachers included Syme and Lister, and on the ophthalmic side Walker and Argyll Robertson.

In 1873, having an introduction to Mr. Couper, he began to attend at the Moorfields Eye Hospital, and in the early months of 1874 worked at the comparative anatomy of the eye under Professor Schäfer at University College, London. During the summer vacation of this year, and for some time in the following year, he was in residence at the Perth District Asylum, Murthly, work which he undertook with the object of examining the fundi oculorum of a large number of lunatics. He was attracted to the subject by the recently published work of Professor Clifford Allbutt, and found the duties congenial. From December, 1874, to June, 1875, he studied in Vienna, chiefly under Jaeger, whom he considered greatly superior to Arlt or Stellwag as a teacher. On his return to London he resumed work with Mr. Couper at Moorfields, where he was appointed junior house surgeon in August, 1876. He became senior house surgeon in December of the same year, retaining this post until November, 1879. His work as a resident medical officer coincided with noteworthy improvements in various directions in the hospital, such as reform of the nursing, a higher standard of notetaking, and better results in the operations for cataract. His influence made itself felt in these matters, and the lastmentioned is perhaps to be attributed in no small degree to his early adherence to Listerian principles. A remark of Syme, in commenting upon one of Lister's cases at Edinburgh, "We are told of pus, we fear pus, we expect pusbut we see no pus," made a great impression upon him as a student, and in Mr. Couper he found a chief who was enthusiastically sympathetic to the new principles.

In December, 1879, he made a voyage to Australia with the special object of collecting the eyes of marsupials and monotremata for microscopic investigation. His work on the comparative anatomy of the eye, which early attracted the attention of Sir William Bowman, appeared in part in the Journal of Anatomy and Physiology ("Minute Anatomy of the Retina," 1877, "The Eye of Ornithorrhynchus," 1884), and elsewhere ("The Embryology of the Retina of Teleosteans," 1888). He assisted in examining the zoological material collected in the Challenger expedition. Much of this work was embodied in his Arris and Gale lectures before the Royal College of Surgeons of England, which were unfortunately not republished. Taking the F.R.C.S. Eng. in 1882, Mr. Gunn wase lected assistant surgeon to the Moorfields Eye Hospital in August, 1883, on the resignation of Mr. Wordsworth, becoming full surgeon in 1888. also appointed ophthalmic surgeon to the National Hospital for the Paralysed and Epileptic, Queen-square, in 1886, and to the Hospital for Sick Children, Great Ormond-street, at about this time. At a later period he held the post of assistant ophthalmic surgeon to University College Hospital. In 1906 he was invited to deliver an address before the American Academy of Ophthalmology and Oto-Laryngology. He chose "Certain Affections of the Optic Nerve" as his subject, putting forward the view that the initial cedema of the disc in cases of cerebral tumour is due to pressure on the small veins of the pial sheath by fluid in the intervaginal space. His death occurred on Nov. 29th, after a painful and distressing illness, which commenced nearly a year ago. He was an early sufferer from influenza and had several attacks; it is probable that his health was seriously undermined by this

complaint. At the time of his illness he was senior surgeon to the Moorfields Hospital, ophthalmic surgeon to the National Hospital for the Paralysed and Epileptic, Queen-square, president of the Ophthalmic Society of the United Kingdom, and a visitor for the King's Hospital Fund. Mr. Gunn leaves a widow and two daughters to mourn their loss.

If the attempt is made to form some appreciation of Mr. Gunn's work for the advancement of ophthalmology a review of his life, such as has been set forth here, shows how early he was attracted to the retina, its anatomy, embryology, and functions. His interest in ophthalmoscopy and in the neurological side of ophthalmology never faltered, but grew stronger as years went on. He was facile princeps in the use of the ophthalmoscope; his descriptions and interpretations of minute changes in the fundus oculi were accepted as the ipse dixit of a master, even by his colleagues at a hospital where, it has been said, ophthalmoscopic examination has gained the position of a fine art. Probably his best known and most quoted contribution is that relating to the ophthalmoscopic evidence of vascular degeneration, the importance of which, not only to ophthalmic science but also to medicine in general, is universally acknowledged. He was among the first, if not actually the first, to realise the gravity of the prognosis as regards life in cases of albuminuric retinitis. In 1886, two years before the publication of Miley's paper on the subject, he wrote: "In my experience it is most exceptional to see an old case of albuminuric retinitis; this latter affection seems to occur at a late stage of the general disease, so that death supervenes before the retinal changes have existed very long." As an authority on the ophthalmoscopic signs of nervous diseases his opinion was undisputed. His enormous experience at Queen-square, utilised to the full as it was by the extreme care and accuracy of his observations, rendered his position in this branch unique, and it will be long before his valuable services to his neurological colleagues can be adequately replaced. His interests, however, were by no means confined to these somewhat narrow channels. He was one of the first to insist upon the value of studying minute changes in the cornea and iris with the strongest available simple microscope, and the lens used by him served as a model for the corneal loupes now in common use. When in Vienna he was impressed by the systematic teaching there, and soon after his appointment to the Moorfields staff he was the means of initiating those courses of study which have led to the establishing of one of the foremost schools of ophthalmology in the world. Nor were his interests confined to ophthalmology. From boyhood he was devoted to outdoor pursuits, especially shooting, botany, marine zoology, and geology. For many years he collected fossils, chiefly fishes and plants of the Jurassic and Old Red Sandstone systems from Scotland to Dorsetshire. It is satisfactory to know that a large number of his most valuable specimens have recently been acquired by the British

Mr. Edward Nettleship, to whom we are indebted for much of the information contained in this notice, writes as follows: "Marcus Gunn's character might be described as little removed from that of the perfect knight—courageous and pure in mind and body, modest, but clear and strong in his convictions, sweet of temper, ready always to see the better side, scrupulous in giving credit where credit was due, but sensitive and quick to resent without respect of persons whatever he judged unworthy in motive or act. He was a man of considerable intellectual gifts and brain power, and an exceedingly keen and accurate observer; his mental grasp was strong, his judgment careful and well balanced; a certain matter-of-fact simplicity was set off by a ready sense of humour. His influence depended largely on the conviction that he was true and loyal to the core and never satisfied with slipshod methods or imperfect knowledge. Himself singularly guileless, he was a good judge of character and motives in others."

Professor Seward of Cambridge writes: "I have never met a more whole-hearted student of nature than Marcus Gunn. During the last 30 years he had spent most of his summer holidays in collecting fossils at Culgower and other places on the coast of his native country, with the result that data are now available of the greatest geological and botanical importance. Marcus Gunn was no mere collector: he regarded nature with the keen scrutiny of a well-trained man of science. The smallest fragment was carefully preserved, and no effort was spared to obtain every available.

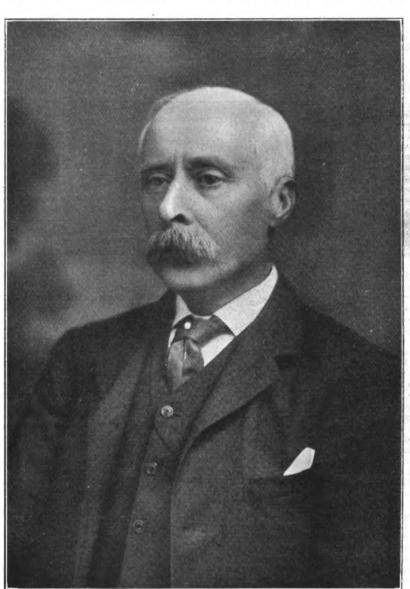

piece of evidence. His aim was to accumulate material which could be used in the interpretation of the records of the rocks, if not by himself by others with more opportunity for paleontological research. His energies were by no means confined to one locality: the collection includes a considerable number of fossil animals; among these may be mentioned a new species of fish which Dr. Traquair named after the discoverer. It is, however, of the plants that I am better able to speak. Thanks to his untiring devotion, it is possible to reconstruct from the fragmentary records the vegetation which flourished in the Upper Jurassic period in the North-West of Europe. Short as my acquaintance with

Marcus Gunn has been, the impression which he made is that of a friend of long standing, whose loveable personality remains as an ennobling recollection. In him were commodesty and high intellectual attainments. The words of one of George Meredith's characters, 'Men of science are always the humanest,' find a striking exemplification in Gunn's life. The courage and patience with which he faced the inevitable are the expression of a true nobility of character and a precious legacy to those who mourn

his loss."
Mr. Percy C. Bardsley writes: "It has been my privilege to work week by week for the last 16 years under the late Mr. Marcus Gunn at Moorfields. His loss to ophthalmology will be recognised all over the ophthalmic world, but it is to express a still greater loss that I write. During these 16 years a vast number of surgeons from Great Britain and Ireland, from our colonies, and from America come to Gunn is the most perfect gentleman I have ever met.' His kindness to his hospital patients was as great as that to his students. His death has created a void in many of our hearts that will never be filled again in this life. Descended from an old Viking family and the last of his name, he was to us the model of a calmly judicious English gentleman."

The Rev. R. C. Gillie writes from Eastbourne: "Perhaps the prevailing impression made on those who knew him best was that of fineness, using the word in all its senses. In manner he was sensitively courteous in a very simple and understanding way, with a touch of Highland distinction blending oddly with his unassuming carriage. In his thinking

he was singularly alert and transparently sincere. Whatever he knew, he knew with perfect clearness, so that a mere layman could delight in his scientific explanations. There was never the slightest concealment of the limits of his knowledge. One felt instinctively that his was a mind from which the last veil of unreality had been lifted and the last trace of evasion removed. Always considerate, even tender to the feelings of others, he was only wrathwith the ful charlatan. with what seemed to him either trickery or pretentiousness politics or science. For such he had no mercy. Speaking of his mental attitude, it is impossible not to touch on his character, for his life was in a marked degree a unity. There was no closed compartment in it. In all his professional and scientific work, his remarkable purity of thought and feeling were as present as in his family and social relations. His patients felt instinctively that

ROBERT MARCUS GUNN, M.A., M.B., C.M. EDIN., F.R.C.S. ENG. (Photograph by Messrs. Elliott and Fry.)

Moorfields to study ophthalmology under Mr. Gunn. I believe that every one of these men will feel, as he reads your obituary notice, that he has suffered a great personal loss. For Mr. Gunn was a friend to all who worked under him. We look back and remember his unfailing urbanity as a teacher; the most junior student could ask him the most elementary question and be sume that he would not be rebuffed, while the older student would receive a lengthy explanation of a difficult case, as lucid as it was complete. He was always ready to give the best out of his wast clinical experience to those who sought for knowledge. Students have remarked to me over and over again, 'I think

they were dealing with a man wholly trustworthy, who was incapable of deception. Trained in the Presbyterian Church, he retained to the end a deep conviction of the reality of the Father of Spirits. His faith had small use for formulas and the ordinary exercises of religion scarcely appealed to him, but humility and reverence were the unmistakeable accompaniments of all his thoughts of the unseen. He rarely broke through the reserve which lay behind the friendly and accessible demeanour. When he did, it was to reveal unconsciously the same clear thinking and lowly minded truthfulness so characteristic of all his life, joined to a wholly beautiful childlikeness. His was the blessing of the pure in heart."

CHARLES ROBERT BELL KEETLEY, F.R.C.S. Eng., L.R.C.P. LOND.,

SENIOR SURGEON TO THE WEST LONDON HOSPITAL, ETC.

By the death of Mr. Charles Robert Bell Keetley our profession has lost a skilful and eminent surgeon, whose life was a good example to all of us of honourable hard work and of devotion to hospital practice. He was the son of Mr. Robert Keetley, a ship-builder, of Grimsby, and was born at Grimsby on Sept. 13th, 1848. He received his medical education at the Hull Infirmary and at St. Bartholomew's Hospital. From the first an able and industrious student, he was awarded a gold medal in anatomy at the University of London. He qualified in 1873, and in 1875 was house surgeon at Queen's Hospital, Birmingham. In 1876 he obtained the Fellowship of the Royal College of Surgeons of England and for some years was assistant demonstrator of anatomy at St. Bartholomew's Hospital. But the true beginning of his surgical career came when he was appointed assistant

surgeon to the West London Hospital. It is not too much to say that no hospital ever had a more zealous and faithful servant. From the day he first went there to the time of his last illness he gave his mind and his strength, often with a sort of extravagance, to its advancement and welfare. During his 30 years of service the West London Hospital grew from a suburban venture to a great general hospital for a million people, to which is affiliated a great post-graduate school. Keetley's name will ever be associated with this development of the place that he loved. He worked incessantly for it, and was often over-worked. On committees, at board meetings, on his operation days he would not leave till the very last thing of all had been done. He disliked having any of his work done for him. Even when his health, a few months ago, began to fail, he still would not take care of himself or hand over a part of his duties to a younger colleague. It is, for example, but a few weeks since he was down at Hammersmith all night undertaking three emergency operations, and there is little doubt that he might have lived longer if he could have been persuaded to allow himself more rest.

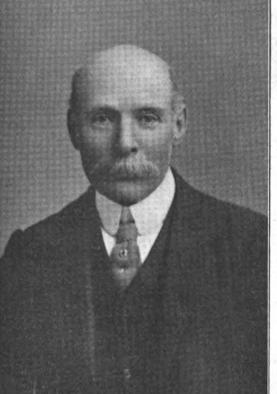

In his treatment of his hospital patients he gave deliberate

and prolonged attention to each case, and, further, was always putting his hand in his pocket for their needs. It will never be known how much money went that way in small sums, but there is not a house-surgeon who has ever served under Keetley who cannot recall his ready sympathy with the material needs of those who came beneath his professional eye. He was far more careful of other people's wants than of his own; and his high place in our profession would have stood even higher if he had been more business-like in his private practice. Often his great experience in operative surgery and his wise judgment in consultation were rated below their value by some colleague whom he had kept waiting, while it was not unknown for a patient to guess rightly that Keetley would soon forget whether he had, or had not, been paid for his attendance It was with him, in this regard, as it was with John Hunter: both men alike were thoroughly methodical in the actual practice of surgery, at the bedside or in the operating theatre, but were inclined to be neglectful of their

work. It would be easy to trace the further likeness between them, for they were men of the self-same temperament, of singular tenacity of purpose and force of will, able to go forward over all kinds of obstacles, and in the end to be successful. Each of them, also, was emotional: readily moved either to anger, or to pity, or to generosity. "All of us, who were Keetley's friends," writes a colleague on the staff of the West London Hospital, "remember that he was quick to take offence, and to show that he was offended, and then, in a moment, he would be no less quick to say something kind and friendly, or even to apologise, in the most delightful way, to a man 20 years his junior. It was not difficult, now and again, to have the sense of a grievance against him; but it was impossible to abide in that most unprofitable of all feelings; the whole thing ended off hand in a better understanding. We found always under the passing vehemence of his manner the steady goodwill of a true friend. He was no more able than Hunter to smile and edge his way through life. he wanted he fought for, with plain speaking, without

hedging or trimming. what he wanted, at the West London Hospital, was always the good of the hospital." Two of its institutions have become inseparable from his memory. One is the West London Medico-Chirurgical Society; he was its founder and its first president; and he received a great part of the happiness of his life from its rapid increase and from the crowded attendance at its meetings. The other is the Ladies' Association. Of this he may truly also be called the founder; and it would be hard to say too much about the admirable, wise, and valuable work which that association has done for the West London poor. These two institutions are of his making, and he lived to see his reward in their great and extending success. The post-graduate school, also, owes much to the loyal support that he gave to Mr. Bidwell in all the hard work of establishing and extending the school to its present membership.

Keetley made a real name for himself both by his practical work in surgery and by his literary work. Many of the profession are familiar with what he did in orthopædic surgery; but in all operations he was no less experienced, independent, and ingenious. In the later years of his

CHARLES R. B. KEETLEY, F.R.C.S.

practice he was especially interested in the operation of appendicostomy, and took a chief part in establishing it in this country. Among his writings, the chief are his book on "Orthopædic Surgery," his very useful "Index of Surgery," which is already in its fourth edition, and his "Student's Guide to the Medical Profession." He was also one of the editors of the first 15 volumes of the "Annals of Surgery." He published many papers of very real value on surgical subjects, his Harveian lecture on Plastic Surgery and his Cavendish lecture on the Conservative Surgery of the Appendix Vermiformis being among the best known of his writings. He was a frequent contributor to The Lancet.

waiting, while it was not unknown for a patient to guess rightly that Keetley would soon forget whether he had, or had not, been paid for his attendance. It was with him, in this regard, as it was with John Hunter: both men alike were thoroughly methodical in the actual practice of surgery, at the bedside or in the operating theatre, but were inclined to be neglectful of their own advantage and of the well-earned payment of their for they are full of the very best kind of humour, while the

very little time that he ever gave to more ambitious painting served to show that he could have excelled here had he chosen. He was an honoured member of the Savage Club, and was an original member, and a President, of the Lincolnshire Society of London. He married the daughter of the late Mr. Henry Holmes Long, of the East India Company, and leaves to her the name of a man of honourable, indomitable mind, generous, warm-hearted, an excellent surgeon, and an excellent friend. She may feel assured that a very large number of persons in all classes and in all parts of the country are sympathising with her in her loss.

Mr. Rickard W. Lloyd writes: "Having enjoyed the friendship of Mr. Keetley for over 30 years, and having received many kindnesses at his hands, I may be excused perhaps for writing of him at this sad moment. Keetley always engaged in his work from a love of the science and a determination to practise it as skilfully and successfully as surgical records showed possible, and to improve upon those records if he could. The courage, thoroughness, ingenuity, and resource which he always displayed was especially shown in the 'eighties' and 'nineties,' when operations were increasing in magnitude and variety almost every day. He was one of the first to adopt Listerian methods, and in his operations he always from the beginning of his hospital career insisted upon thoroughness in antiseptic preparations and precautions. And though so bold a surgeon he was a very careful one. He allowed as little blood as possible to be lost, and he liked his patients to have the minimum of the anæsthetic administered, preferring ether to chloroform. I saw him on the day before he last went to Brighton (where he hoped to throw off a harassing cough, and where, alas! he died) open a knee-joint and remove a large thick fringe from its interior. Elsewhere he performed an operation for radical cure of a very large scrotal hernia. Those cases were in private practice. Afterwards, on the same day, I saw him at the hospital excise a malignant growth involving coils of intestines. Such is an ordinary sample of the operations he had been performing on several days a week for so many years, and the general verdict upon Keetley's mass of varied, bold, and ingenious operative work must be that the results were extraordinarily good. Keetley's social talents were great, despite his infirmity of deafness. He was exceedingly interesting, original, and generally amusing in his speeches, and a very clever artist. Many years ago in the dissecting room at St. Bartholomew's Hospital when he was a demonstrator, I remember the enlightening drawings in coloured chalks that he made in explaining dissections, and the kindliness and the readiness with which he always assisted us as students. I have since seen him illustrate his surgical work scores of times with clever drawings which he made with amazing rapidity and exactness. I have seen many humorous and caricature drawings that he has made when out of the range of some speaker-and unfortunately deafness, his great misfortune in life, often placed him there.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Marcus P. Hatfield, professor of pediatry in the Chicago College of Physicians and Surgeons.—Dr. Theodor Sümisch, formerly professor of ophthalmology in the University of Bonn.—Dr. Max Jordan, extraordinary professor of surgery in the University of Heidelberg, at the early age of 45 years. He was for many years assistant to Professor Czerny, and had published a number of researches and encyclopædic articles on surgical subjects.—Dr. Kell, oberarzt of the Plauen Municipal Hospital, from blood-poisoning contracted in the performance of his hospital duties.

ROYAL MICROSCOPICAL SOCIETY.—At a meeting of the Royal Microscopical Society held on Nov. 17th Mr. Edward Heron-Allen read a short paper on the Recent and Fossil Foraminifera of the Shore Sands of Selsey Bill in Sussex, many hundreds of foraminiferous shells being at the same time exhibited as lantern pictures. Mr. Conrad Beck showed for Mr. J. W. Gordon a microscope lamp possessing several novel features, one of them being that when the light was focussed on an object the image of the incandescent filament or other source of light was not visible in the field. Several ladies were present, this being the first meeting which the rules permitted them to attend.

NOTES FROM CHINA.

(FROM OUR OWN CORRESPONDENT.)

Climatic Bubo.

A7 the Budapest meeting of the International Medical Congress in the section of Tropical Medicine a discussion was raised by Professor Gabbi of Rome on the subject of climatic bubo, and though the account given in your issue of Sept. 18th was necessarily a brief summary, it was not difficult to see that there was considerable doubt in the minds of almost all the speakers as to whether the disease is a specific and separate morbid entity. For some years past I have been puzzled by this complaint, and having been fortunate to meet with a series of eight cases during the past year I may perhaps be allowed to add a few notes concerning it. The cases occurred among Europeans; five of these belonged to a regiment which had arrived a little over a year ago from South Africa. The other three were foreigners who have been resident in Peking for several years. None of the cases showed signs of venereal disease, though six had from time to time exposed themvears. selves to the chance of infection. As in the case of tuber-culous joints, the patients usually give a history of having injured themselves, remembering an instance where they felt a sudden pain on some occasion, but none of the incidents mentioned were such as would cause mischief in glands not already inflamed. The groin glands were swollen, hard, painless, and in six of the cases suppuration took place. In the other two there was no raised temperature throughout, nor was there any leucocytosis, filariasis, or malaria. Beyond finding staphylococci, and, in one case, streptococci in the pus, there was no trace of other bacterial organisms uniformly present which could be accounted etiological factors. There are cases of gonorrhoa in which long after the gonococcus has disappeared one can still find staphylococci in the urethral mucus, and it is necessary to pay particular attention to the clinical history and to look for any possible signs of venereal disease. The health otherwise of these cases was unaffected, and the general physique was good. One inclines to the opinion that this disease is due to inflammation caused by some toxin rather than direct invasion by bacteria. It awaits a more than direct invasion by bacteria. It awaits a more particular investigation, as the view held that it is due to a lessened resistance to microbic infection does not in any way advance matters. As for treatment, complete rest is the most prudent course, and two weeks in bed will sometimes, but not always, tide over the chance of suppuration, but where this does take place simple puncture by a bistoury and application of a Bier's suction glass renewed three or four times, once daily, will be found a more expeditious treatment than by extirpation or scraping. In employing the last method small glands which are not touched by the spoon take up the burden of the scraped glands and considerably lengthen the period of recovery. Internally, iodferratose or the syrupus ferri iodidi of the Pharmacopecia are useful. The tissues surrounding the glands are free from inflammation; in fact, there are absolutely no other clinical symptoms beyond the localised groin glandular swelling. Climatic bubo is a diagnosis of comparatively recent date, but from the experience of other medical men in China who have met with cases of it the general feeling is that it is a distinct and separate pathological entity the etiology of which is still unknown.

Research Work in China.

The above paragraph deals with only one of many medical problems which await detailed investigation on the spot. A short time ago the leading Shanghai paper, the North China Daily Ners, drew attention to the wide scope for research work locally and invited the ratepayers to take up the matter and secure the services of an expert pathologist to work in the municipal laboratory. The administrative duties of the medical officer of health and his assistants leave them scant time for devoting themselves to research. The causes of variation in virulence of small-pox vaccine; cholera antitoxic serum: the suitability of fruits and vegetables as media for the growth of certain pathogenic organisms; preventive inoculation against cattle plague; the causation of beri-beri; the incubation period of rabies in China; the prevalence of Malta fever, sprue, and dysentery are but a few

of the questions which require elucidation. The paper suggested that the schools of tropical medicine in England, America, and the Continent should be invited to avail themselves of the use of the well-equipped municipal laboratory by sending out experts to undertake research along certain defined lines. There can be no doubt of the field for such work, and a hint might be dropped here to our English tropical schools of medicine to look to their laurels in this matter, for it appears that American universities have already formulated plans for establishing research laboratories in China. The University of Pennsylvania has already undertaken, in Canton, the establishment of a medical school that shall have well-equipped research laboratories and whose staff shall consist of men fully qualified to conduct investigation. Harvard, Yale, and Virginia Universities have also formulated plans. One of the outline schemes is as follows:—

Research Department.—Investigation concerning diseases peculiar to China. All the instructors to be men engaged in such study, and capable of imparting the spirit of inquiry to their students. The training of men who shall be the leaders in research in China. Study of methods for improving the hygiene of the population. Emphasis on preventive medicine, with inaugurations of campalgns of education regarding infectious diseases. Exact studies regarding the principles of hygiene for Westerners in the tropics, emphasising especially diet and clothing. While wishing every success to the fulfilment of this scheme, the would be a pity if the responsibility for medical research and education and all the opportunities it offers should be allowed to be assumed by American universities alone. There is plenty of room for all, and, as far as England is concerned, the good work at present being so conscientiously carried out by British doctors at Shanghai, and at medical schools such as those at Peking, Hankow, Hangchow, &c., shows that up to the present moment England is in the forefront

Oct. 27th.

of the movement.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Medical Privilege.

The Full Court of Victoria held last year that under Section 55 of the Victoria Evidence Act a medical man could not disclose communications made to him by a patient nor disclose any knowledge acquired from his professional observation. A case has just been brought forward in which the National Mutual Life Assurance Company declined to pay a death policy on the ground that the holder had suppressed facts as to her health on taking out the policy. The company relied for their case on the evidence of Mr. E. T. Thring, of Sydney, but according to the previous decision his evidence could not be taken. The matter is to be taken to the High Court on appeal.

Melbourne Medical School.

The annual report of the Dean of the Faculty of Medicine sets out that the number of medical students on the Register was higher than in any previous year. The figures given for students taking full courses were in 1908: males, 302; females, 21; total 323; 1909: males, 311; females, 15; total 326. The recognition of St. Vincent's and the Alfred Hospitals as clinical schools was completed, and there was reason to believe that facilities for teaching would be much increased in the new Melbourne Hospital. The proposals made by the faculty and approved by the council under the Stewart bequest should greatly stimulate the teaching of anatomy, physiology, pathology, medicine, and surgery, and a new department of neurology was contemplated. A committee has been appointed to revise the curriculum. At the last Australasian Medical Congress, out of 800 members 300 were trained in the Melbourne school.

Veterinary School, Melbourne.

Professor Gilruth, the recently appointed professor of veterinary medicine in the Melbourne University, reports that the Research Institute, to which is attached a dissecting-room, is nearing completion. Plans for a general veterinary hospital and operating theatre were being prepared, and everything should be in readiness for the opening of the session of 1910.

Private Hospitals in Melbourne.

A statement has recently been made that a number of socalled private hospitals in Melbourne are in reality places of

doubtful, or more than doubtful, repute. The chairman of the Board of Health states that he has found that only 12 private hospitals are legally on the register. The Act requires registration to be renewed annually, but has hitherto apparently been ignored by all concerned. A report was being prepared, but the town solicitor advised that the existing regulations only gave power to supervise the structural requirements, and did not permit of any objection to the character of the persons in charge.

Melbourne Hospital Elections.

A scheme has been prepared by the staff of the Melbourne Hospital with the intention of abolishing the present system of staff election by vote of subscribers. Under the proposed scheme the members of the present staff remain in office until the age of 60 years, and changes from the outdoor to indoor appointments are to be made in order of seniority. Future appointments to the staff are to be made by the hospital committee acting on the advice of a special board, to be composed of representatives of the University, of the staff, and of the committee. This advisory board would examine the credentials of candidates and make a selection, so that practically it holds the power of appointment. The general committee has not yet finally dealt with the proposal, but so far it has not manifested any keen sympathy. Only two or three members of the staff are adverse to the scheme, which will in all probability be eventually adopted, though possibly with some modification as to the automatic succession from outdoor to indoor appointments. It is not contended that the present system has resulted in any notable faulty appointment, but the scenes connected with the election have rendered existing methods distasteful to the majority of those called in to take part. A strong point has been made of the fact that five or six of the most promising younger practitioners have refused to face the election ordeal for the Melbourne Hospital, and have joined the staff of another institution.

Hospital Sunday, Melbourne.

The Hospital Saturday and Sunday collection in Melbourne just taken has resulted in a larger total than that of any year since 1888, when the "boom" was at its zenith. The amount received is £7372, an increase of nearly £300 on the previous year. The largest individual collection was made by the police and totalled £935. The denominational collections as usual seem to show the Presbyterian adherents as much the most wealthy.

Dental Congress.

The second congress of the dental profession in Australasia was opened on Oct. 25th at the Wilson Hall of the Melbourne University by the Governor-General. The president of the congress was Mr. J. Iliffe of Melbourne, and vice-presidents were appointed from all the other Australian states and New Zealand. Many papers have been contributed by leading practitioners in England and the continent.

Tuberculosis in New South Wales.

At a gathering in aid of the Consumptive Home at Strathfield Sir P. Sydney Jones stated that the loss of life from tuberculosis in New South Wales during the last 33 years amounted to 42,912 persons. Assuming each of these meant a loss of £200 to the State, it represented a total loss of £8,500,000 out of a total population which did not amount to 2,000,000.

Insanity in Australia.

Dr. Eric Sinclair, Inspector-General for New South Wales, reports that the number of officially insane under cognisance in that State on Dec. 31st, 1908, was 5705. The increase for the year was 98, which was below the average of the last 20 years. The proportion of insane to the general population was 1-281. The average cost per patient was £30 17s. 10_2d . per annum. In Queensland the number of insane under control on Dec. 31st, 1908, was 2189, an increase of 111 on the previous year, which is more than double the average annual increase for ten years past. The proportion of insane to population is given as 3.92 per 1000. The cost per patient was £22 2s. 9d. Dr. J. B. Cleland reports the number of insane in South Australia as 1051, an increase of 32, and the proportion to population about 2.50 per 1000.

Oct. 26th.

Medical Rews.

UNIVERSITY OF OXFORD.—The following have passed the examination for the Diploma in Public Health:—

Part I.—C. V. Ascrappa, M. N. Balsara, H. M. Crake, J. Fortune, S. K. N. Kabriji, J. B. Mama, W. S. Stalker, L. R. Tosswill, and W. F. J. Whitley.

Part II.—J. Fortune, I. C. Keir, W. S. Stalker, and L. R. Tosswill.

Foreign University Intelligence.-Albany Medical College: Dr. Victor C. Myers has been appointed Assistant Professor of Chemistry and Toxicology. —Cairo: Dr. Engel Bey, Director of the Statistical Department of the Board of Health, has been granted the title of Professor by the Prussian Ministry of Education.— Genoa: Dr. A. Morselli has been recognised as privatdocent of Psychiatry. - Göttingen: Dr. Hans Doering, privat-ducent of Surgery, has been granted the title of Professor. - Grat: Dr. Otto Loewi of Vienna has accepted the chair of Pharmacology and Pharmacognosis. -Königsberg: Dr. Hans Strehl, privat-docent of Surgery, has been granted the title of Professor.— Memphis Medical College: Dr. E. S. Cain has been appointed Lecturer on Medicine and Pharmacology; and Dr. A. D. West as Lecturer on Surgery and Orthopædics.—Naples: Dr. Francesco Accordini has been recognised as privat-docent of Internal Pathology.—Palermo: Dr. N. La Meusa has been recognised as privat-docent of Dermo-syphilo-pathology. Rome: Dr. Angelo Isaia has been recognised as privat-docent of External Pathology; Dr. Alfonso Neuschüler as privatdocent of Ophthalmology; and Dr. F. Laureati as privatdocent of Pediatry. - Rostock: Dr. Th. Geis is retiring from his Professorship of Surgery. - Tübingen: Dr. Karl Schlaver, Oberar:t of the Medical Clinic, has been awarded the Karl Faber prize for his researches on the pathology of the kidneys. -Turin: Dr. E. Martini has been recognised as privat-docent of Surgical Pathology.

A STUDY IN THE HEREDITY OF JEWISH SCHOOL CHILDREN.-Professor Karl Pearson has written to the Education Committee of the London County Council stating that recent work at the Francis Galton Laboratory of National Eugenics, University College, seems to indicate that heredity is far more closely related than environment to the physique and mentality of the child, and asking for permission to conduct an investigation, as regards their vision, of the parentage and home conditions of Jewish children in certain schools in the East-end of London. The mode of procedure would be to examine the eyesight of all the children in the schools selected, and to make inquiries at their homes, where the extent of Hebrew character-reading and the size and lighting of the rooms would be noted, as well as other indications of good or poor environment, and the opinion of the teachers would be obtained as to the state of the clothing, &c., of the children. The astigmometer would be the only instrument used and the home inquiries would be conducted by persons of wide experience of Jewish families. mission asked for has been granted provided that the experiments are conducted under the supervision of the medical officer.

LONDON POST-GRADUATE ASSOCIATION.—We are informed that the London Post-Graduate Association is enlarging its scope. As is now well known, the association issues cards which admit to any part of the clinical instruction at the several institutions which is open to their own students, including operations and post-mortem examinations, for a moderate fee. For those practitioners who desire to see as many cases as possible within a short period the association supplies a very real need; but the time has now come when it is felt that London should take a more important place as a centre for post-graduate study, and with this end in view special classes for qualified medical men only are being held at the following hospitals: University College Hospital, the Westminster Hospital, the Brompton Hospital for Consumption and Diseases of the Chest, the National Hospital for the Paralysed and Epileptic, and the Medical Graduates' College and Polyclinic. For these classes a small additional fee is charged, and information concerning them can be obtained at the individual hospitals. The office of the London Post-Graduate Association

is now at 20. Hanover-square, London, W., where the secretary may be seen daily between the hours of 10.30 and 1, except on Saturday. Particulars may also be obtained on written application.

UNIVERSITY OF LONDON.—At a meeting of the Senate on Nov. 17th the following were added to the panel of lecturers in physiology:—Mr. W. B. Hardy, M.A., F.R.S., Professor A. F. Stanley Kent, M.A., Dr. V. H. Veley, D.Sc., M.A., F.R.S., and Professor Swale Vincent, M.D., D.Sc. Sir T. Lauder Brunton has been appointed chairman of the Physiological Committee, and Professor H. R. Kenwood, M.B., D.P.H., and Professor W. J. R. Simpson, C.M.G., M.D., F.R.C.P., D.P.H., have been appointed representatives of the University at the Third International Congress of School Hygiene to be held at Paris in August, 1910

GUARDIANS AND TUBERCULOSIS.—The Treatment of Consumptives Committee of the Eastbourne board of guardians has circularised the 12 boards in the county of East Sussex, stating that it was of opinion that consumptive patients should be removed from the workhouse infirmary and provided for in a special building arranged on sanatorium principles, and asking each board to send delegates to a conference to consider a proposal to secure the combination of boards of guardians in the county for the purpose of providing separate accommodation for the isolation and treatment of patients suffering from phthisis. Ten of the 12 boards have offered to send delegates, and the conference, it is proposed, shall be held at Lewes early in the new year. A similar conference to that proposed in East Sussex was held at Croydon earlier in the year representative of boards of guardians in the county of Surrey.

RELIEF OF DESTITUTE CHILDREN IN BRIGHTON.-The work of the Brighton Police-aided Scheme for Clothing Destitute Children is to a certain extent explained by its title, but some figures and facts presented at the annual meeting on Nov. 30th still further unfold the splendid character of the work. While on their beats policemen become accustomed to seeing young children day after day perhaps going to, or returning from, school. If they think they are insufficiently clad inquiries are made, and if the parents are deserving the child participates in a periodical share-out of clothing during the winter months. This year 851 children-487 boys and 364 girls-were relieved in this manner. But the work has not ended here. In the last 12 months the same scheme has also supplied 60 girls between 14 and 19 years of age with complete outfits for domestic service; situations were found for all of them, and nearly all of them are now earning a livelihood. Seven cripples were also supplied with crutches. It is noteworthy that a good deal of the clothing distributed is made by the policemen's wives at the Police Institute.

THE COTTAGE BENEFIT NURSING ASSOCIATION AND THE STATE REGISTRATION OF NURSES. -On Dec. 7th Lady Ancaster presided at the half-yearly meeting of the general council of the Cottage Benefit Nursing Association at Denison House, Vauxhall Bridge-road. The secretary, Miss Broadwood, having read the report which appealed for more subscribers, the Hon. Sydney Holland addressed the meeting on the subject of the State registration of nurses. He said that he opposed registration because it would tend to deteriorate nursing and not improve it. The supporters of registration claimed that if nurses were registered the public would have a guarantee that a nurse had had a proper training and was a suitable person for the work. No one had ever suggested that registration should be compulsory. Character and suitability were as important as technical knowledge, and character could not be tested by examination. Too much was made of examinations nowadays. From his own experience he knew that many nurses, who passed examinations did not make the best nurses, and some who came out at the top could never make good nurses. If registration were adopted the standard of examination would have to be low in order that the necessary number of women might pass the test. Nurses would not submit to a hospital training if the State said that only registration was necessary to become a good nurse. Examination would lower the standard of technical knowledge. Hardly any medical man would be so stupid as to recommend a nurse simply because she was on the Register. He would want to know something about her character. With regard to the public, the question only concerned the rich. The poor had such nurses as the Queen's Jubilee Nurses, the nurses of an association such as the Cottage Benefit Nursing Association, and the Poor-law and infirmary trained nurses. Registration would not even be a guarantee of technical fitness, for the methods of treatment were constantly changing and the physical capacity of the nurse might also change. In order that the public might judge of the training which a nurse had had, Mr. Holland suggested the publication of an official directory.

ROYAL COLLEGE OF PHYSICIANS OF LONDON: THE WEBER-PARKES PRIZE AND MEDALS.—The next award under this foundation will be made in 1912, and the adjudicators have selected as the subject of the essay for that occasion: "The Influence of Mixed and Secondary Infections upon Pulmonary Tuberculosis in Man, and the Measures, Preventive and Curative, for Dealing with Them." All essays, together with any preparations made in illustration of them, must be transmitted to the registrar of the College during the last week of May, 1912, in accordance with the regulations relating thereto, copies of which will be forwarded from the College on application. The award will be made at some time previous to Oct. 18th in that year, on which day the prize and medals will be presented to the winners.

UNIVERSITY OF DURHAM.—The King in Council has been pleased to appoint the Duke of Northumberland, Sir Hugh Bell, Bart., Miss E. M. N. Williams, M.D. Lond., D.P.H. Cantab., Mr. G. G. Butler, M.A., Mr. J. S. G. Pemberton, M.A., and Mr. John Wilson, M.P., to be members of the Senate of the University. At a meeting of the council of the University of Durham College of Medicine, Newcastle-on-Tyne, Sir George Hare Philipson, M.B., the President of the College, and Mr. J. E. Gibson, M.A., were unanimously elected as the two representatives of the council of the College to act on the Senate, as constituted under the University of Durham Act, 1908, while Dr. David Drummond and Professor Robert Howden were appointed to represent the Academic Board of the College on the new Senate.

CENTRAL MIDWIVES BOARD.—Special meetings of the Central Midwives Board were held on Dec. 1st and 2nd at Caxton House, Westminster, with Dr. F. H. Champneys in the chair. The Board considered the following charges amongst others against the midwives whose names are given below, and ordered them to be struck off the roll. Mercy Glew, that notwithstanding repeated warnings she persistently neglected to provide herself with a clinical thermometer or to take any steps to render herself competent to read the same, and that having been duly suspended from practice by the local supervising authority on account of having been in contact with a case of puerperal fever, she nevertheless continued to attend women as before, without having disinfected herself, her clothing, and her appliances to the satisfaction of the local supervising authority. Mary Ann Richardson, that being in attendance as a midwife at a confinement, the patient suffering from an offensive discharge, and having complained to her that she felt very ill, she did not send for a doctor. Elizabeth Taylor, that being in attendance as a midwife at a confinement, the patient suffering from puerperal fever, she did not send for a doctor. Georgina Martha Winfield, that being in attendance as a midwife at a confinement, the patient suffering from continual sickness and from diarrhoa, with a temperature of 103° F., she did not send for a doctor. Jane Booth, that being in attendance as a midwife at a confinement, the patient being ill, suffering from scarlet fever, she did not send for a doctor. Emily Bussey, that being in attendance as a midwife at a confinement, the patient being ill, suffering from suppressed lochia and headache, she did not send for a doctor. Jane Philpot, that being in attendance as a midwife at a confinement, the patient being seriously ill, with symptoms of puerperal mania, she did not send for a doctor. Louisa Blendell, Jane Finnegan, Mary Jane Rowlands, and Mary Ann Massey, that they were uncleanly and did not take with them to confinements the appliances and antiseptics required by the rules of the Board. Sentences on the following midwives after charges alleged against them had been considered were deferred: Mary Elizabeth Cornwall, Mary Morrall, Mary Jane Whittle, Catherine Williams, Elizabeth Gazey, and Susannah Morgan.

ROYAL SOCIETY OF MEDICINE.—A special general meeting of the Fellows of the Royal Society of Medicine will be held on Wednesday next, Dec. 15th, at 5 p.m., to consider a scheme, approved by the Council of the Society, for raising the money necessary to erect a suitable building on a new site. The scheme has far-reaching issues with regard to the future of the Royal Society of Medicine, and its adoption will no doubt be approached with due caution and, we trust, in the presence of a full attendance of Fellows.

THE BATTERSEA BROWN DOG MEMORIAL.—On Wednesday night the Battersea borough council decided, on the motion of Dr. L. S. McManus, seconded by Dr. J. T. Richards, to endeavour to arrange for the removal of the offensive inscription on the Brown Dog Memorial at Battersea and to substitute a truthful one. The recommendation of the Highways Committee was that the solicitor should negotiate for the return of the memorial to its donors. A deputation attended and urged that there should be no interference with the memorial or at most that the inscription should be altered in a manner agreeable to all parties. Brown Dog was said to have an "educational value." During the discussion it was pointed out that the Commissioner of Police had written stating that special police protection was costing £700 a year. A member said a memorial which was the cause of so much acrimony and expense was necessarily a nuisance and ought to be removed.

University of Liverpool.—Three new lectureships were instituted by the Council of the University of Liverpool at its meeting on Nov. 30th on the recommendation of the Senate and of the Faculty of Medicine: (1) a lectureship in orthopædic surgery to which Mr. Robert Jones. Ch.M.Liv., F.R.C.S. Edin., was appointed; (2) a lectureship in physiology, to which the present assistant lecturer and demonstrator, Dr. H. E. Roaf, was appointed; and (3) a lectureship in pharmacology, to which Mr. Owen T. Williams, M.B. Lond., M.R.C.P. Lond., was appointed. The lecturer in orthopædics will deliver a course of lecture-demonstrations during the summer term, which will be open to graduates and undergraduates alike. The lecturer in physiology will take special charge of the chemical physiology department. The lecturer in pharmacology was temporary lecturer in the subject during the last two sessions, he will supervise pharmacological research, and will hold a class in practical pharmacology, which is in the third year of the curriculum for the degree.

PROPOSED OPEN-AIR SANATORIUM FOR WORKING-CLASS CONSUMPTIVES IN MIDDLESEX .- For some time a movement has been on foot, having for its object the provision of an open-air sanatorium for working-class consumptives in the county of Middlesex. In furtherance of this object a largely attended meeting was held recently at Hillingdon Court, Uxbridge, by the kindness of Lord and Lady Hillingdon. The meeting was addressed by, amongst others. others, Dr. J. L. Lock (medical officer of health of the Uxbridge urban district), Dr. A. Charpentier (medical officer of health of the Uxbridge rural district), and Dr. J. J. Perkins (honorary secretary of the National Association for the Prevention of Consumption). It was pointed out at the meeting that the deaths from consumption in the county were nearly one-tenth of the total death-rate. A resolution was ultimately adopted supporting the scheme. Part of the money will be raised by a 20,000 crowns fund, subscriptions to which will be invited from all classes; when the sum has been collected and a beginning made an appeal will be issued for larger subscriptions. It is intended to erect buildings which, when completed, will accommodate 100 patients, and it is believed that by spending as little as possible on buildings (which will be on the pavilion plan) the total cost will not exceed £100 per bed. A start will be made as soon as £5000 have been raised, it being hoped to provide 30 beds, together with the administrative buildings, for this sum. Further accommodation will be added as funds permit. The beds are to be for the use of all suitable Middlesex cases whose cost of maintenance is guaranteed either privately, or by the local authorities, or other bodies or persons maintaining beds. The total cost per patient, it is considered, ought not to

exceed 25s. per week in a sanatorium with 100 beds. was originally intended that public authorities should be asked to pay for the cost of establishing the beds they would maintain, but this was found unworkable in Middlesex. It is proposed to appoint a local representative in each district to supervise the local collection of funds, and the local banks will be asked to receive subscriptions. Mr. Andrew Clark, F.R.C.S., was elected representative for the Uxbridge district at the meeting.

A LECTURE on "The Prevention of Tuberculosis, the Larger Outlook," will be delivered on Monday, Dec. 13th (and not on the 15th, as had been previously announced), at the Municipal Buildings, Tottenham, by Dr. R. W. Philip of the Royal Victoria Hospital for Consumption, Ediphysh. Edinburgh. Entrance will be by tickets, which can be obtained from the medical officer of health of Tottenham.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Prorogation of Parliament.

PARLIAMENT was prorogued on Friday, Dec. 3rd. Amongst the Acts which received the Royal Assent on that occasion was the Housing and Town Planning Act.

HOUSE OF COMMONS.

THURSDAY, DEC. 2ND. The Prison Commission.

The Prison Commission.

Sir Philip Magnus asked the Secretary of State for the Home Department whether a vacancy was shortly to occur on the Prisons Commission; and whether, having regard to the fact that the commissionership which might be vacant had been held for some years by a member of the medical profession, he would undertake, in the event of the occurrence of a vacancy, to appoint a member of the medical profession to the post.—Mr. Gladbrone replied: It is true that Dr. Donkin, one of the Prison Commissioners, retires shortly under the age rule, but I hope to be able to make arrangements which will ensure the continuance of the invaluable services which Dr. Donkin has rendered to the medical side of prison work. I hope at the same time to increase the strength of the prison administration in order to enable it to meet the greatly increased responsibilities thrown upon it by recent legislation.

Infantile Mortality.

Infantile Mortality.

Mr. James Stuart asked the President of the Local Government Board whether he could state the number of deaths in England and Wales of infants under one year per 1000 births in each of the years 1904 to 1908, and in the first nine months of each of these years and of 142 present year, distinguishing London, the 76 great twens, and the 142 smaller towns from the rest of the country.—Mr. Burns replied (by written answer): The following tables give the information asked for:—

I .- Infant Mortality in each of the Years 1904 to 1908.

_	Deaths under one year to 1000 births in the years—						
	1904	1905	1906	1907	1908		
England and Wales	145	128	132	118	121		
76 great towns, including London	160	140	145	127	129		
London	145	130	131	116	113		
142 smaller towns	154	132a	138	122	124		
England and Wales, less the 218 towns	125	113b	116	106	110		

II .- Infant Mortality in the First Nine Months of each of the Years 1904 to 1909.

	Deaths under one year to 1000 births in the first three quarters of each of the years—							
	1904	1905	1906	1907	1908	1909		
England and Wales	149	131	135	113	115	106		
76 great towns, including \Loudon	165	142	148	118	123	114		
London	149	129	133	110	110	104		
142 smaller towns	157	136a	140	118	117	107c		
England and Wales, less the 218 towns	127	1166	117	104	105	97d		

a, 141 small town b, less 217 towns; c, 143 small towns; d, less 219

Appointments.

Successful applicants for Vacancies. Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANGET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

Bell, C. W., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Dunoon District of the county of Argyll.

BOYLE, JAMES, M.B., C.M. Glasg., has been appointed District Medical Officer by the Cardiff Board of Guardians.

BREND, W. A., M.B. Lond., Barrister at Law, has been at Lecturer in Forensic Medicine at Charing Cross Hospital.

COATS, GEORGE, M.D. Glasg., F.R.C.S. Eng., has been appointed Ophthalmic Surgeon to the Hospital for Sick Children, Great Ormond-street

BDMOND, G. M., M.D., M.S. Aberd., has been appointed Medical Officer to the Post Office at Aberdeen.
 GEE, OSWALD ARNOLD, M.B., C.M. Edin., has been appointed District Medical Officer by the Gloucester Board of Guardians.

GRIFFITHS, J. HOWELL, M.D., B.S. Lond., D.P.H. Lond., has been appointed Medical Superintendent at Gore Farm Hospital, Dartford.

LL, A. T., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Llanrwst District of the counties of Carnarvon and Denbigh.

PEPPER, A. J., M.S., M.B. Lond., F.R.C.S. Eng., has been appointed Consulting Surgeon to St. Mary's Hospital.

ROBERTS, C. HUBERT, M.D. Lond., F.R.C.S. Eng., M.R.C.P. Lond., has been appointed Physician to In-patients at Queen Charlotte's Lying-in Hospital.

Pacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BIRKENHEAD BOROUGH HOSPITAL.—Junior Resident House Surgeon. Salary £80 per annum and fees.

BRIGHTON, HOVE, AND PRESTON DISPENSARY.—House Surgeon. Salary £130 per annum, with board and residence.

CARDIFF INFIRMARY (GENERAL HOSPITAL).—House Surgeon for the Ophthalmic and Bar and Throat Departments for six months. Salary £30, with board and laundry.

CHARTHAM, KENT COUNTY ASYLUM.—Third Assistant Medical Officer. Salary £145 per annum, with board, quarters, attendance, and washing.

DERBYSHIE ROYAL INFIRMARY.—Two House Surgeons, a House Physician, and an Assistant House Surgeon. Salaries of three former £100 per annum, and of latter at rate of £60 per annum, with apartments, board, &c.

DEVONPORT, ROYAL ALBERT HOSPITAL.—Resident Medical Officer, unmarried. Salary £100 per annum, with apartments, board, &c.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—Medical Officer for six months. Salary at rate of

Shadwell, E.—Medical Officer for six months. Salary at race of £100 per annum, with luncheon and tea.

ENFIFELD AND EDMONTON ISOLATION HOSPITAL, Winchmore Hill.—
Resident Assistant Medical Officer. Salary at rate of £150 per annum, with rooms, rations, and washing.

GRIMSBY AND DISTRICT HOSPITAL.—House Surgeon. Salary £120 per annum, with board, lodging, a'tendance, and washing.

Hemple Hempstead, West Herf's Hospital.—House Surgeon. Salary £100 per annum, with rooms, board, and washing.

Hôpital Français, 172, Shaftesbury-avenue, W.C.—Second Resident Medical Officer, unmarried. Salary £50 per annum, with full board and laundry. board and laundry.

Indian Medical Service, India Office, London.—Thirteen Commissions in His Majesty's Indian Medical Service.

LISTER INSTITUTE OF PREVENTIVE MEDICINE, Chelsea-gardens, S.W.— Senior Assistant in the Bio-Chemical Department. Salary £350 per annum.

LIVERPOOL INFIRMARY FOR CHILDREN.—Resident House Surgeon.

Also Resident House Physician. Salaries at rate of £60 per annum, with board and lodging.

LONDON HOSPITAL, Whitechapel, E.-Anæsthetist.

LONDON LOCK HOSPITALS.—House Surgeon to the Female Hospital, Harrow-road, W. Also House Surgeon to the Male Hospital, 91, Dean-street, Soho, W. Salary in each case £100 per annum, with board, lodging, and washing.

MANCHESTER, NORTHERN HOSPITAL FOR WOMEN AND CHILDREN, Park-place, Cheetham Hill-road.—Anæsthetist. Salary £15 per annum.

MIDDLESBROUGH, NORTH RIDING INFIRMARY.—Assistant House Surgeon, unmarried. Salary £75 per annum, with residence, board, and washing.

MIDDLESEX HOSPITAL MEDICAL SCHOOL. -Lecturer on Mental Diseases.

MIDDLESEX HOSPITAL, W .- Assistant Ophthalmic Surgeon.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Hampstead and Northwood.—House Physician. Salary £75 per annum, with board, residence, &c.

NEWARK-ON-TRENT HOSPITAL AND DISPENSARY.—Resident Medical Officer, unmarried. Salary £100 per annum, with board, lodging, and laundry.

NORTHAMPTON GENERAL HOSPITAL.—House Surgeon. Salary £90 per annum, with apartments, board, &c.

POPLAR HOSPITAL FOR ACCIDENTS, Poplar, E.-Radiographer.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.—Assistant Resident Medical Officer for four months. Salary at rate of £50 per annum, with board, residence, and washing.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E.— House Physician for six months. Salary at rate of £60 per annum, with board, residence, and laundry.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—Weber-Parkes Prize of 150 guineas and two silver medals.

ROYAL EYE HOSPITAL, Southwark, S.E.—Honorary Assistant Surgeon. St. Marylehone General Dispensary, 77, Welbeck-street, Cavendish-square, W.—Honorary Medical Radiographer. Also Honorary Surgeon.

SHEFFIELD, EAST END BRANCH OF THE CHILDREN'S HOSPITAL.—
House Surgeon to Out-patients. Salary £70 per annum, with
board, lodging, and washing.

Sherrife Droyal Hospital.—Assistant House Surgeon. Also Assistant House Physician. Salary £50 per annum each, with board, lodging, and washing.

Sheffield Union Hospital, Firvale.—Assistant Medical Officer (female). Salary £100 per annum, with apartments, rations, &c.

SOUTHAMPTON, FREE EYE HOSPITAL.—House Surgeon. Salary £100 per annum, with board and residence.

VICTORIA HOSPITAL FOR CHILDREN. Tite-street, Chelsea, S.W.—House Physician for six months. Salary £30, with board, lodging,

WEST BROMWICH DISTRICT HOSPITAL.—Resident Assistant House Surgeon, unmarried. Salary £75 per annum, with board, residence, and washing.

WEST HAM AND EAST LONDON HOSPITAL, Stratford, E .- Honorary Dental Surgeon.

West London Hospital and Post-Graduate College, Hammer-smith-road. W.—Clinical Assistants, Throat, Nose and Ear, Skin, and X Rays, Pathological Laboratory, &c.; and Three Casualty Officers.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.-House Salary at rate of £80 per annum, with board, rooms, and

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Goole, in the county of York; at Harpenden, in the county of Hertford; and at Holywell, in the county of Flint.

Births, Marriages, and Deaths.

BIRTHS.

SAVILL.—On Dec. 3rd, at "St. Albans," Sea-road, Bexhill, the wife of Philip Savill, M.D., of a son.

WALKER.—On Dec. 2rd, at Kensington-crescent, the wife of Captain N. Dunbar Walker. R.A.M.C., of a daughter.

WARD.—On Nov. 30th, at The Tiled House, West Byfleet, Surrey, the wife of V. Godsalve Ward, M.D. Lond., of a son.

MARRIAGES.

DAVIDSON—DARBYSHIBE.—On Nov. 30th, at Holy Trinity Church, Brompton, Duncan Davidson, M.B. Oxon., M.R.C.S., L.R.C.P., of Coventry, to Beatrice Alice, daughter of Mr. and Mrs. Darbyshire of Pietermaritzburg.

BENSLEY.—On Dec. 5th, at Kelfield-gardens, North Kensington, W., Charles Egbert Wimond Bensley, M.D., Lieutenant-Colonel, late I.M.S. (retired), and H.E.I.C.S., in his 76th year.

BLAKE.—On Dec. 4th, at Old-court Mansions, Kensington, Frederick William Blake, M.D., Deputy Inspector-General, R.N., aged

William Blake, M.D., Deputy Inspector-General, R.N., aged 85 years.

COCHRANE.—On Dec. 4th, at Middlesex Hospital, James Mackeand Cochrane, M.D., aged 57 years.

HARVEY.—On Dec. 8th, at 85, Approach-road, Bethnal Green, H., William Harvey, M.P.S., in his 77th year, who for nearly fifty years faithfully discharged the duties of Dispenser at the City of London Hospital for Diseases of the Chest (Victoria Park Hospital). Funeral service will be held at the Church of St. James-the-Less, Bethnal Green, on Saturday, at 2.30 P.M. Interment at Hford.

KEETLEY.—On Dec. 4th, suddenly, at Brighton, Charles Robert Bell Keetley, F.R.C.S., senior surgeon to the West London Hospital, of Grosvenor-street, London, W., aged 61 years.

WARD.—On Nov. 28th, at his residence, Belmont, Castle Connell, Ireland, Major Espine Charles Robert Ward, F.R.C.S.I., late Army Medical Staff, aged 61 years.

N.B.- A fee of 5s. is charged for the Insertion of Notices of Births,

Hotes, Short Comments, and Answers to Correspondents.

A QUESTION OF PRIORITY.

WE have received a letter from Dr. J. Miller of Glasgow, which refers to a question of priority in research and in which he asks us to correct a false impression given by a report in THE LANCET of Sept. 7th, 1907, p. 704. The report in question was an abstract of a communication read before the Pathological Section of the British Medical Association at the Exeter meeting two years ago, and began with these words: "Dr. David Lawson (Banchory) then detailed some observations upon The Elimination of Opsonius by the Exerctory Organs, which had been carried out in the Banchory Laboratory in conjunction with Dr. James Miller." This report did not come to Dr. Miller's notice at the time but has since been quoted in a book on Vaccine-therapy which on its authority attributes the research in question to Dr. Lawson and not to The fact was that Dr. Miller carried out the investigations in the laboratory at the Nordrach-on-Dee Sanatorium as the guest of Dr. Lawson, who quoted the results at the Exeter meeting, but with the sanction of Dr. Miller, to whom he attributed the work. We have Dr. Lawson's full assurance of this, for as soon as Dr. Miller had communicated to him the passage in the book to which we have referred he replied that he was scrupulously careful to preface his remarks at Exeter by stating that the investigation was not his own, but that the credit of the ideas and their carrying out was Dr. Miller's, and that if the work had been published in such a way as to give a different impression it had neither his sanction nor approval. Dr. Lawson has also written to the author who quoted our report asking him to accord Dr. Miller his proper credit in future issues of his book. We may add that we published Dr. Miller's complete observations in THE LANCET of April 4th, 1908, under the title of "Note upon the Tuberculo-Opsonic Index of the Urine and Sweat in Health and Tuberculous Disease.

We, perhaps, inadvertently did an injustice to both Dr. Miller and Dr. Lawson, and are glad to take this opportunity of giving the former gentleman the credit of his research and of clearing the latter of an imputation which cannot fail to be unpleasant to any scientific observer.

"DR. GUILLOTIN."

To the Editor of THE LANCET.

SIR,-Dr. Watkin W. Jones is probably better acquainted with the history of the guillotine than myself. In venturing to question the validity of the claim he seeks to establish for Louis I have simply quoted from Lenotre, who is responsible for my statements.

Lenotre attributes distinctly the invention to Guillotin. The merriment to which Dr. Watkin Jones alludes, and with which (according to the Monitcur) Guillotin's remarks were received, referred not to the proposal itself, but to the jocular offer of cutting off the heads of the members of the constituent assembly without their knowing it. The machine chosen, says Lenotre, was "celle qu'avait proposé l'auteur de la machine." Louis was only consulté and submitted an avis motire. report, in which he speaks of instruments in use previously in Germany, Denmark, and England which might serve as a model.

A certain Guédon was then commissioned to make a machine in accordance with the description of Louis, but this was not done, and Guillotin "qui tenait à son idée" applied to Samson, exécuteur des hautes auvres, and the instrument which was first tried on Pelletier was ultimately constructed by a friend of Samson called Schmidt. Speaking of hecatombs of victims decapitated shortly after "on peut * demander," says Lenotre, "ce qui serait advenu si le Dr. Guillotin n'avait pas conçu le sinistre héritier de son nom." I will add (alwayaccording to Lenotre) that Louis is said to have been greatly grieved at his name being attached to the invention. The subsequent change of designation might be taken also as indicating that Guillotin was chiefly concerned in the invention.-I am, Sir, yours faithfully,

Route de la Croix, Le Vesinet, Nov. 30th, 1909. OSCAR JENNINGS.

FRAUDULENT DIPLOMAS IN RUSSIA.

SOME years ago the Russian Minister of the Interior, with the object of suppressing the name "dentist" in favour of the term "doctor of dentistry" for those who had gone through a dental course in special schools, issued a circular forbidding dentists to receive pupils. But for such students as were already being taught by dentists he fixed a period for examination in the universities, conditional on the presentation of a certificate by their teachers. Now that the latest period for such examination is running out, a peculiar form of Russian towns. It has been found that in Kieff, Smolensian and other large towns, doctors of dentistry have been giving false certificates to people who have never been connected with them, and those who bought the certificates submitted them to the university and obtained in exchange a dental degree carrying with it the right to reside anywhere. As a conse quence, says the journal, a large number of Jews have settled in

certain towns and are engaged in various businesses, not necessarily in the dental direction. It is averred that as many as 5000 such degrees have been issued. According to the Smolensk Viestnik, many arrests have taken place in connexion with this fraudulent practice, including medical officers in the public services. Particulars of a similar fraud have also been published. Of late many applications have been made to the Kieff University for verification of dispensers' certificates, of which large numbers, it would appear, have been forged and sold, and owners of pharmacies have been obliged to apply to the universities alleged to have issued the certificates to verify them before engaging dispensers.

PRINTING "IN REVERSE."

To the Editor of THE LANCET.

SIR,-With reference to the recent letter of "Amateur Printer." may recall a note which appeared in the Rapid Review of April, 1904, which reviewed an article in the Leisure Hour? It was stated that two scientists had invented a reformed alphabet and recommended that the characters should be "white on black" instead of "black on white," and also that the speed of recognition was about ten times less in the latter style than the former. This has always seemed to me somewhat doubtful. I have also heard that the private newspaper of the Paris croque-morts (undertakers' men) is thus printed, although I have never seen a copy. I would remind readers of THE LANGET whose sight is impaired of "a very simple contrivance to aid myopic and other failing eyes, especially in reading," used and recommended by Sir W. ... Gairdner, whose letter with the foregoing heading was published in THE LANCET of Oct. 1st, 1904, p. 980. I tried it and found it useful.

I am, Sir, yours faithfully, London, Nov. 30th, 1909.

DANGEROUS HAIR DYES.

DURING the past few years nitrate of silver has to some extent been replaced in hair dyes by paraphenylene-diamine, with the result that numerous cases of poisoning have been reported in the medical journals. The chemistry of this substance and its mode of action are described in the Pharmaceutical Journal of Oct. 30th. The toxic effects are attributed to the formation, by exidation, of quinone di-imide, which is a powerful irritant both of the skin and of the mucous membrane. One of the most popular hair dyes containing paraphenylene-diamine is put up in two bottles, one containing hydrogen peroxide solution, and the other an ammoniacal solution of the dye. The hair is directed to be freed from grease, after which the dye solution is applied and then the bydrogen peroxide. It is said that in skilful hands it is possible to obtain fine tints, but the preparation is a dangerous one. Another formula directs the solution of the dye in a mixture of water, glycerine, and alcohol, with or without ammonia. If ammonia be present it is not considered necessary to remove grease from the hair before applying the solution. Even more dangerous hair dyes are prepared from paraphenylene-diamine and diamidophenol with potassium bichromate, the proportions of the ingredients being varied according as a black, brown, or blonde tint is desired. Such preparations sometimes cause actual burns, followed by an extensive eczema which is very difficult to cure. In one form or another the use of paraphenylene-diamine as a hair-dye has been repeatedly shown to cause these troubles, accompanied by itching, urticaria, nausea, nervous symptoms, sleeplessness, dizziness, epileptiform attacks, and syncope, and in several instances death has resulted.

HEALTH MATTERS IN SOMALILAND PROTECTORATE.

Mr. H. E. S. Cordeaux, C.B., C.M.G., Commissioner of this Protectorate. in his report to the Colonial Secretary for the year ended March 31st. 1909, estimates the population (no actual census having ever been taken) at about 350,000, including about 100 Europeans and whites. The general public health during the year was good and there was no serious outbreak of disease of any kind. There was an increase in the number of patients attending the hospitals pretty evenly distributed. This increase has not affected the death-rate or the number of in-patients, and may be attributed to the large number of cases of simple skin diseases. Every endeavour has been made to keep a supply of simple drugs to meet these requirements. The three coast hospitals are chiefly visited during the winter months— Berbera, for example, having a population of from 20,000 to 30,000 during that time, whereas during the summer 3000 to 4000 is probably an outside figure. This variation has to be taken into account when considering statistics. This migratory condition of the population is due to the excessive heat on the coast during the summer, the impossibility of feeding stock in the neighbourhood, and the many conditions governing trading of all sorts. There are two great considerations which materially affect the general public health. These are, first, that the people are practically all Mahommedans, and therefore total abstainers from alcohol; and, secondly, the indifferent precaution taken either against excessive heat by day or chill at night by the Somalis. In connexion with abstinence from alcohol, Mr. Cordeaux considers there "may be mentioned the very marked difference shown under anæsthetics by the Somalis as compared with European and other races addicted to the use of this stimulant. Serious respiratory trouble is practically never met with and struggling is quite unusual, yet the people are of a both nervous and excitable temperament. In few cases only do the natives either smoke or take tobacco or its usual concomitant, coffee. Regarding the second condition to which I

have drawn attention, the native dress is the same by day as night and consists of cotton only. Wool is seldom, if ever, worn, nor is the Somali provident enough to provide himself with a blanket. Taking this into consideration we account for a very large percentage of the total cases of respiratory diseases, rheumatism, and nerve pains. The application of another Somali trait of character goes some way to explain their freedom from sun troubles, for, in contradistinction to the imported Indians, they drink an incredibly small amount of fluid when exposed to the sun on the march, being fully convinced that by such indulgence staving power is affected and heat stroke more liable to occur both in man and beast. In regard to the general sanitary condition of the protectorate and its chief towns, the Com-missioner testifies that a considerable improvement has taken place. General civil hospitals exist at the three coast towns of Berbera, Bulhar, and Zaila. At Berbera there are also an isolation hospital for tuberculous patients and a single-ward building for the accommodation of small-pox cases. A disinfecting station also exists at Berbera consisting of two rooms and a caretaker's hut; this is furnished with a small "Clayton disinfector" capable of meeting all probable requirements. Bulhar and Zaila are provided with temporary matting huts or tents to meet any contagious disease outbreak. The inland or up-country camp hospitals are at Sheikh and Burao. At the former the civil camp hospital exists separately from the military hospital, whilst at Burao civil and military patients are attended by the military medical officer, the Civil Medical Department furnishing a part of the equipment. The number of patients treated at the civil hospitals in the year 1908 was 17,012, as compared with 10,458 in

SMELLS AND THEIR CLASSIFICATION.

To the Editor of THE LANCET.

SIR,-It is said that "necessity is the mother of invention," therefore it seems that there has been only small inconvenience to our predecessors by the absence of smell classification, otherwise such would have been accomplished long ago. With the advent, or I should say the perfection, of the education of the present day, I think that there arises now some call for classification of smells. When I was a student it struck me very forcibly that medical lecturers laboured under a great difficulty in describing the article or substance they had to dea! with in the absence of the specimen, whereas they could describe the colour, taste, consistence, but when it came to smell they were baffled completely. For the want of a standard, the vocabulary so far as the adjectives are concerned was used profusely, and at the end of it all no one was any the wiser as to the character of the smell. To illustrate my point I will refer you to the British Pharmacoporia, 1885, a product of a very learned body, and therein you will find the smell of musk described as follows: "A very strong, diffusible, penetrating, musk described as follows: persistent odour." With all With all these qualifying terms a student is as remote from knowing the exact smell as he was before. In the present Pharmacopula the learned authors have tried to improve the description by saying that musk has "a very characteristic, penetrating, persistent odour." You will find a large number of similarly ambiguous descriptions of smells throughout the Pharmacopæia and other books dealing with subjects allied to medicine.

The layman generally describes a smell as a "stink" or a "scent," and a lady describes it as "horrid" or "lovely." The sense of smell may be normal, absent, intensified, deficient, or perverted. When normal I daressy it means the acuity of the sense of smell in the majority of persons. When absent we say they have "anosmia." This affliction has its advantages as it enables them to enjoy stale London eggs as if they were new laid. Some have too keen a perception of smell, or "hyperosmia." This is very marked in the blind. Isaac of old said to Jacob, "Thy smell is not the smell of Esau." I came across a gentleman who kept his ipecacuanha powder in a remote corner of the dispensary, and he told me that if anyone removed the stopper he would at once perceive the smell and would have an attack stomach-ache, and I had proof of the accuracy of his words.

The sense of smell is intensified by the administration of strychnine. In some cases we have a perversion of the sense of smell, "parosmia." This is of great clinical importance. A strange smell is often the aura in epilepsy and sometimes the precursor of insanity. There are some persons, if I may use the term, "smell-blind." A fellow student who afterwards did some chemistry with me for the D.P.H. used to gloat over the lovely (as he called it) perfume of bisulphide of carbon. He afterwards became one of the medical inspectors at the Local Government Board. The sense of smell is the function of the olfactory nerve which also distinguishes the various flavours, and this may be the reason why so many persons cannot distinguish smell from taste. four primary tastes are sweet, bitter, acid, and salt, and these have no effect on the olfactory nerve; hence paralysis of this nerve does not delete the sweet, bitter, acid, or salty character of substance, but does of the flavouring agents. But paralysis of the glosso-pharyngeal and certain fibres of the fifth nerve destroys the sense of taste but not flavour. Some of the senses are very fully classified, vision and hearing in particular; probably these give the greater pleasure to the great majority. We have primary and secondary colours, and therefore to describe a colour as "horrid" would not be acceptable, although such passes muster for the smell. In the case of hearing, the classification is so complete that you can describe the musical notes from the grunt of the pig to the song of the nightingale.

Passing on to the classification of smells, some years ago, when

working specially in chemistry, I did bottle up some characteristic smells, and concected a name for each. I do not recollect the details of that work, but it leaves an impression on me that some classification of smells ought to be possible. In the selection of odoriferous substances one recognises the importance of choosing pure definite chemical bodies so as to avoid mixed smells, and that they should be capable of ready dilution, as strong odours not only quickly temporarily paralyse the olfactory nerve endings but also irritate the fifth nerve. The concocted names of the primary odours should be easily adapted to affixes and prefixes. Having adopted the standard of odours and their names, I would suggest sets of them at the elementary schools to familiarise the children with them and their names, as is done at present in the case of colours. The foundation laid of an octave of smells it would not be so difficult as hitherto to impart more definitely and intelligently the character of a smell to others in legal and medical

As a preliminary classification of the primary odours we might select such bodies as (1) ammonia; (2) sulphuretted hydrogen; (3) bromine; (4) valerianic acid; (5) ether; (6) menthol; (7) camphor; (8) artificial musk; (9) nitro-benzol. Next we have to concoct a name for each of these odours apart from the names of the substances, such as is done For example, red does not pertain to any particular substance, but is the quality of large numbers, and we can qualify the quality in various ways, such as reddish-vellow and reddish-brown, or yellowish-red and brownish-red.

After settling the primary odours and name we could, I think, in the same manner describe the odours fairly well of a larger number of I am, Sir, yours faithfully, substances.

Nov. 22nd, 1909. MORRIS J. WILLIAMS.

WANTED-A SIMPLE PURINOMETER.

- A CORRESPONDENT wishes to hear of a simple inexpensive method and apparatus for estimating purins in urine. There is a process (given in Boston's "Clinical Diagnosis") which has a simple apparatus devised by Camerer, but he cannot find it in any instrument catalogue at his command. The only apparatus which he can find in the lists
- G. R. I. (Whalley Range).-The information contained in your legal correspondent's letter is correct. Anyone can notify a death and is at liberty to express an opinion of its cause, but no one but a registered medical practitioner can give a statutory death certificate.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Meek.

ROYAL SOCIETY OF MEDICINE, 20, Hanover-square, W.

TUESDAY.

MEDICAL SECTION: at 5.30 P.M.

Joint Debate:

On the Diagnosis and Treatment of Duodenal Ulcer, opened by Mr. B. G. A. Moynihan, followed by Sir T. Lauder Brunton, Bart., Mr. Herbert Waterhouse, Dr. W. Hale White, Dr. A. F. Hertz, Dr. R. Hutchison, and others.

DERMATOLOGICAL SECTION (Hon. Secretaries—E. G. Graham Little, H. G. Adamson): at 5 p.m.

Case and Specimens:
Dr. T. D. Savill: Scierodermia.
Dr. George Pernet: Sections of Melanosis Cutis.
Mr. J. MacDonagh: Trichoepithelioma Papulosum.
Dr. Graham Little: (1) Telangiectatic Lupus Brythematosus; (2) Tertiary Syphilis.
Mr. G. W. Dawson: (1) Acne Keloid; (2) Bazin's Disease: (3) Case for Diagnosis.

ELECTRO-THERAPEUTICAL SECTION (Hon. Secretaries—Reginald Morton, G. Harrison Orton): at 8.30 p.m.

Paper:
Dr. N. S. Finzi: Radium in the Treatment of Malignant
Growths.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendiah

MONDAY.—8.30 P.M., Prof. A. Keith: Recent Researches on the Anatomy of the Heart.—Dr. T. Lewis: Auricular Fibrillation.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, 17, Blooms-

SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish square, W.

FRIDAY.—8.30 p.M., Discussion on Tick Fever (opened by Sir William Leishman).—Paper read for Dr. A. Balfour (Khartoum) and Captain D. Thomson, R.A.M.C. (Khartoum): Two Cases of Non-ulcerating Oriental Sore, better termed "Leishman Nodules" (with photograph).

LECTURES, ADDRESSES, DEMONSTRATIONS, &c. BOYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoin's Inn Fields, W.C. MONDAY, WEDNESDAY, AND FRIDAY.—5 P.M., Dr. G. E. Smith: The Evolution of the Brain. (Arris and Gale Lectures).

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22,

College Street, W.C.

Monday.—4 P.M., Dr. J. Galloway: Clinique (Skin). 5.15 P.M.,
Lecture:—Dr. F. Powell: Some Diseases of the Larynx, with
Special Reference to Hoarseness and Loss of Voice.

Tuesday.—4 P.M., Dr. W. Ewart: Clinique (Medical). 5.15 P.M.,
Lecture:—Dr. P. Kidd: Some Points in the Clinical History of
Praymonia

Pneumonia.

WEDNESDAY.—4 P.M., Mr. T. H. Openshaw: Clinique (Surgical).

5.15 P.M., Dr. E. I. Spriggs: The Physiology of the Appetite, with Special Reference to the Arrangement of Meals and the Use of Tonics.

URSDAY.—4 P.M., Sir Jonathan Hutchinson: Clinique (Surgical), 5.15 P.M., Lecture:—Dr. R. Hutchison: Some Conditions which

Simulate Dyspepsia.
FRIDAY.—4 P.M., Dr. StClair Thomson: Clinique (Throat)

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-

Oad, W.

MONDAY.—10 A.M., Lecture:—Surgical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays.

Mr. Dunn: Diseases of the Ryes. 2.30 P.M., Operations. 5 P.M.,
Lecture:—Mr. Armour: Practical Surgery.

TUESDAY.—10 A.M., Dr. Moullin: Gynecological Operations. 12.15 P.M., Lecture:—Dr. Pritchard: Practical Medicine. 2 P.M.,
Medical and Surgical Clinics. X Rays. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Operations. Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. R. Morton: X Ray Department.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children.
Dr. Davis: Diseases of the Throat, Nose, and Ear. 12.15 P.M.,
Lecture:—Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. B. Harman: Diseases of the Ryes. 2.30 P.M., Operations. Dr. Robinson: Diseases of Women. 5 P.M., Lecture:—Mr. Pardoe: Bacterial Infections of the Urinary Organs.

Women. 5 P.M., Lecture:—Mr. Pardoe: Bacterial Infections of the Urinary Organs.

Thursday.—10 A.M., Lecture:—Surgical Registrar: Demonstration of Cases in Wards. 12 noon, Pathological Demonstration:—Dr. Bernstein. 2 P.M., Medical and Surgical Clinics. X Rays.

Mr. Dunn: Diseases of the Ryes. 2.30 P.M., Operations. 5 P.M., Mr. Dunn: Purulent Conjunctivitis.

FRIDAY.—10 A.M., Dr. Moullin: Gynacological Operations. Medical Registrar: Demonstration of Cases in the Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Davis: Diseases of the Throat, Nose, and Kar. 2.30 P.M., Operations. Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Mr. Etherington-Smith: Clinical. Clinical.

Clinical.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Mr. B.
Harman: Diseases of the Eyes. Dr. Davis: Diseases of the
Throat, Nose, and Bar. 12.15 p.m., Lecture:—Dr. G. Stewart:
Practical Medicine. 2 p.m., Medical and Surgical Clinica.
X Rays. 2.30 p.m., Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadmought Hospital, Greenwich.

NDON SCHOOL OF CLINICAL MEDICINE, Dreadmought Hospital, Greenwich.

Monday.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery.

3.15 P.M., Sir Dyce Duckworth: Medicine. 4 P.M., Mr. R.
Lake: Rar and Throat. Out-patient Demonstrations:—10 A.M.,
Special lecture:—Sir Dyce Duckworth: On the Diatheses.

TUSBDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Wells: Medicine.

3.15 P.M., Mr. Carless: Surgery. 4 P.M., Sir M. Morris:
Diseases of the Skin. Out-patient Demonstrations:—10 A.M.,
Surgical and Medical. 12 noon, Skin.
Wednesday.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor:
Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient
Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Rys.

Thursday.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine.
3.15 P.M., Sir W. Bennett: Surgery. 4 P.M., Dr. SaleBarker: Radiography. Out-patient Demonstrations:—10 A.M.,
Surgical and Medical. 12 noon, Ear and Throat. 3.15 P.M.,
Surgical and Medical. 12 noon, Ear and Throat.

Special Lecture:—Sir William Bennett: The Use of the Thermo-cautery in Surgery.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 2.15 P.M., Special Lecture:—Dr. Rose Bradford: Nephritis.

SATURDAY.—2 P.M., Operations. Out-patient Demonstrations:— 10 A.M., Surgical and Medical. 11 A.M., Sye.

SATURDAY.—2 P.M., Operations. Out-patient Demonstrations:—
10 A.M., Surgical and Medical. 11 A.M., Eye.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
MONDAY.—Clinics:—10 A.M., Surgical Out-patient (Mr. H. Rivans),
2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose,
Throat, and Ear (Mr. H. W. Carson). 4.30 P.M., Medical
In-patient (Dr. A. J. Whiting).

TUESDAY.—Clinic: 10 A.M., Medical Out-patient (Dr. A. G. Auld).
2.30 P.M., Operations. Clinics:—Surgical (Mr. W. Edmunds);
Gynæcological (Dr. A. E. Glies).

WEDNESDAY.—Clinics: 2-.230 P.M., Medical Out-patient (Dr. T. R.
Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks).
3 P.M., X Rays (Dr. H. Pirie). 4.30 P.M., Lecture:—Dr. A. H.
Pirie —The Treatment of Ringworm by X Rays.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed succlusively "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTI-PICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager.'

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES. TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANGET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

Until the end of the present year copies sent by post will be charged at the rate of $7 \pm d$. inland and 8d. abroad

Commencing with the issue of Jan. 1st, 1910, the rates of subscriptions, post free from THE LANCET Offices, will be :-

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs. 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch') should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA-Messes. WILLIAM WOOD AND Co., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

O 0 6
Situations wanted: First 30 words, 2s. 6d.: per additional 8 words, 6d.

Quarter Page, £1 10s. Half a Page, £2 15s. An Entire Page, £5 5s.

An original and novel feature of "THE LANCET General Advertiser," is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an additional advertisement.

Advertisements (to insure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to advertisements; copies only should be forwarded.

Changes and Post Office Order (accessed World and Accessed
should be forwarded.

Chaques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager,

Mr. Charles Group, The Langer Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE Langer can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

The Bradshaw Tecture

O.N

THE BRAIN STRUCTURES CONCERNED IN VISION.

Delivered before the Royal College of Surgeons of England on Dec. 11th, 1909,

By FRANCIS BICHARDSON CROSS, M.B. Lond., F.R.C.S. Eng.,

CONSULTING OPHTHALMIC SURGEON TO THE BRISTOL ROYAL INFIRMARY AND SURGEON TO THE BRISTOL EYE HOSPITAL.

COMPARATIVE ANATOMY.

MR. PRESIDENT AND GENTLEMEN, -In the lower vertebrata a simple brain is formed by enlargement of the anterior end of the spinal cord and by the widening and division of its central canal to form ventricles. Upon this primitive brain swellings are developed in connexion with the sense of sight and smell. The sense of smell seems first of early importance probably for selection between nutritious or poisonous foods or a means of safety. In fishes we find the risual organs well developed and varying in importance with the necessity in the species for more or less perfect sight: optic lobes and tracts, an optic chiasma and infundibulum, a third, fourth, and lateral ventricles and corpora geniculata underneath the optic thalamus. These often vary conversely in importance with the olfactory region, which is enlarged when smell is the more needed function. In all fish the optic nerves cross quite separately one above the other, from one eye to the opposite optic lobe, or one nerve may pass through a slit in the opposite one.

In amphibians the brain is usually of low type but rather large. In the proteus, which is practically blind, the optic lobes are scarcely recognisable, but in the frog they are large and form the broadest part of the brain. In the reptilia the brain is long and narrow, but it has become much increased in size and is well differentiated, and we get a very definite cerebral cortex. The three mantles of the brain exist as found in mammals: (1) the basal pallium or pyriform; (2) the marginal pallium or hippocampal; and (3) the

neopallium or higher cortex (brain proper).

The brain in birds is broad and highly developed, enlarged chiefly by the size of the corpora striata. All the structures upon which sight depends are very well developed. The thalamus and optic lobes are highly organised, and there are even present small temporal and occipital lobes. In birds the optic chiasma is single and complete and crosses over the infundibulum. The bundles of fibres from each optic nerve interlace and alternate, but those of each nerve completely decussate to the opposite side. The optic tracts pass round the optic thalami and show well-developed geniculate bodies. In birds of prey, where rapid coordination between the seeing and capturing of their prey is essential, the optic lobes are very strongly developed. Vision is, as a rule, panoramic, one eye for each side. (The fowl sees its food one eye at a time.) The owls and hawks, whose eyes look forward and who undoubtedly possess a considerable field of binocular vision to enable them to catch their living prey; probably no fibres from the optic nerve pass direct without decussation. Their vision is binocular, but not stereoscopic, for which direct as well as decussating fibres are required.

In the marsupials the brain becomes still more highly organised. On the mesial surface of the hemispheres there appears a sulcus which runs horizontally behind and parallel with the hippocampal. This is the calcarine, or splenial, about which the cortical substratum for vision is placed; it is one of the earliest, best defined, and most constant fissures of the brain, and it can already be shown to form the calcar avis in the ventricle. A genual and a rostral sulcus also show on the mesial surface of the hemisphere,

although no corpus callosum as yet exists.

When we reach the placental mammals a corpus callosum becomes developed and completes the three great commissures with the anterior and the hippocampal. In the colugo (insectivora) the sulci on the brain become more marked; the most definite is a deep calcarine sulcus running horizontally forward, almost the whole length of the mesial No. 4503,

surface of the hemisphere; there are also very large anterior quadrigeminal bodies. In the many families of rodents there is a peculiar absence of sulci, especially on the mesial aspect of the brain, and the calcarine fissure is rarely seen. The squirrel requires very accurate sight, and he has large optic nerves and very developed anterior quadrigeminal bodies. The rabbit and the hare probably possess a very acute sense of hearing. They live to avoid being captured. The eyes are placed so much on the side of the head that each carries an enormous range over its field of vision, and they can see laterally and behind almost as well as in front. This wide panoramic vision cannot well be associated with any great binocular effort; nearly all the optic nerve fibres decussate.

In the carnivora the brain proper is highly developed; it passes forward over the olfactory bulb and backward over the cerebellum. There is a very high degree of binocular vision. In the fruit-eating carnivora the eyes are at the side of the head and they possess only a limited con-But in the felidæ and others the eyes are set vergence. forward and the pupil is very active. These animals require good distant vision, often when the light is dull, and they also need very reliable closer sight and a most perfect coordination of the eyes with the fore limb, by which they catch their prey. In the optic chiasma there are considerable direct as well as decussating fibres. There is a deep calcarine sulcus which with the intercalary shuts off a posterior lobe from the rest of the brain. In some species there appear secondary fissures, running out of the calcarine or even a definite retrocalcarine.

The ungulata are large animals and they need a large brain, but the mesial area is very simple. There is no high specialisation in the calcarine fissure; it is large and placed behind the splenium. It joins the intercalary and this the genual, showing a complex splenial or a form of cingular arc. The eyes are usually placed on the side of the head and separated by the forehead or nose. There is a wide area of periscopic sight, but they only have a limited amount of convergence and binocular vision. In the horse about

one-sixth of the fibres decussate.

In periscopic vision each eye is responsible for the field on its own side, and as this is represented on the opposite side of the brain all the optic nerve fibres must decussate. When the eyes tend to converge and give slight binocular vision a part of the nasal side of each field is overlapped. The superimposed parts have crossed to the opposite side of the middle line. The extreme nasal side of the right field is now concerned with the left field of vision, and the fibres that represent this must go to the opposite side of the brain. As the eyes turn more forward more and more of the nasal fields overlap, and more and more direct fibres are required. In perfect stereoscopic vision both visual axes must be turned towards the object looked at. The whole nasal field is carried across the middle line; we thus have an almost complete overlapping of the two fields, and, what is more important, overlapping of the objects seen by the two maculæ.

In the monkeys the calcarine sulcus becomes the centre of further developments. In the aye-aye and lemurs it is somewhat vertical, but in the tamarin, one of the anthropoid apes, and marmoset, a long single sulcus is prolonged horizontally far back into an elongated occipital lobe, which measures nearly half of the brain. In the squirrel monkey (cebidae) almost half the hemisphere lies behind the splenium. In this large occipital lobe the calcarine sulcus terminates in a wide-shaped bifurcation, and several other compensatory calcarine sulci are developed. The collateral runs forward on its ventral side and from its dorsal runs up a parietooccipital sulcus close behind the intraparietal. macacus we have the higher organisation of the old-world monkeys: the smell organs are well seen but diminishing. The long bifid retrocalcarine, the callosal and the parietooccipital with the intraparietal sulci are well developed, and the general conformation of the brain, especially in the occipital lobe, closely resembles that seen in man.

THE VISUAL PATH IN MAN.

The optic chiasma has very important relations with the third ventricle and with the structures adjoining it; and lesions involving this ventricle would be likely to cause visual symptoms. The lamina cinerea, the very vascular anterior perforated space" and the tuber cinereum, are

important relations of the optic chiasma, and bitemporal defects of the visual fields might be expected to arise from many directions. In some cases of primary optic atrophy I have seen a narrowing of the nasal fields which I have taken to be due to some error in the anterior perforated space. Acromegaly seems undoubtedly to depend on a diseased condition of the pituitary body, and the close relationship of the latter with the chiasma accounts for the early onset of bitemporal hemianopsia. Bitemporal hemianopsia from implications of the chiasma may, however, be very marked without any symptoms of acromegaly, and therefore presumably without implications of the pituitary body. The fibres in the chiasma are decussating, direct, and intercerebral.

About 80 per cent. of the retinal fibres pass through the lateral geniculate body, the other 20 per cent. go to the nucleus of the pulvinar of the optic thalamus. The geniculate fibres are directly associated with vision. Those that pass through the pulvinar (which is closely allied in structure and probably in function to the geniculate body) do not go with the others to the calcarine area. They have no doubt some special function connected with sight, but they pass independently to other centres; some of them probably go to the neighbourhood of the angular gyrus. Degeneration of the pulvinar, if the geniculate bodies are intact, does not produce hemianopsia. The upper half of the external geniculate body seems to correspond with the upper quadrant of the retina.

The axis processes from the optic tracts and lateral geniculate bodies traverse the posterior end of the internal capsule at the junction of its superior and inferior laminæ behind the lenticular body, and then pass directly backward as the optic radiations towards the occipital lobe. They run as the optic radiations towards the occipital lobe. along the outer wall, roof, and floor of the posterior horn of the lateral ventricle, and end in the nervous felt-work of the occipital cortex along the calcarine fissure. The occipitothalamic radiations consist chiefly of "corticipetal fibres" for sight, but "corticifugal fibres" also pass along them to the superior brachium and quadrigeminal colliculus, and thence to the oculo-motor nerves. By Campbell these corticifugal fibres are thought to be the axones of Meynert giant cells in the occipital cortex.

If the visual region of the occipital cortex is removed on one side the lateral geniculate body of the same side undergoes atrophy, particularly in the cells. The pulvinar does not seem much altered. If the eyes are extirpated the tract undergoes atrophy in the grey matter between the cells, but the cells themselves are not affected. Lesions of the retina cause degeneration in the intercellular grey matter of the geniculate body, which is mainly composed of ramifications of the retinal fibres. The visual path has its anterior neurons running from the retinal elements to arborise in the cells of the external geniculate bodies, and from them the posterior neurons run on to nerve cells in the occipital cortex in and around the calcarine fissure. It is therefore not the retinal fibres, but the fibres of the external geniculate body that are projected upon the occipital lobe.

THE VISUAL CORTEX.

The calcarine fissure, which in man commences a short distance behind and below the splenium, was first well described by Cunningham. It consists of an anterior part or "stem," the "true calcarine fissure," which protrudes into the posterior horn of the lateral ventricle as the "calcar avis." The fissure as it passes backwards appears to bifurcate into the posterior or "retrocalcarine" and the occipito-parietal fissures; really, however, the latter is separated by the annectant cuneal gyrus, and the former by the deep anterior annectant cuneo-lingual gyrus. posterior calcarine itself also seems to bifurcate behind into an upper and lower vertical fissure, the "fissura extrema" or "terminalis," but it is really separated from them by the posterior annectant cuneo-lingual gyrus.

If sections are made through the cortex of the occipital lobe there is seen running across the calcarine fissures, and parallel to the grey matter which covers the surface of the lobe, a well-marked easily seen white line. The line is due to the presence of a special plexus of nerve fibre running in the cortex and traceable for a considerable distance within its deeper surface. This is known as the line of Gennari. Elliot Smith has most carefully described its disthe area over which it passes can be easily identified. It runs in the grey substance of the occipital lobe, following the sulci and convolutions, and by means of its presence the area concerned in vision can be accurately mapped out. Though it appears as a line in sections of the brain, it is really, of course, a layer of special tissue, which forms part of the thickness of the cerebral grey matter, and lies half-way between the surface and the underlying white matter of the

At the retrocalcarine fissure it is seen to line the hollow and both sides of the sulcus, and it reaches upward on the cuneal gyrus and downward on the lingual gyrus, as far as the two small sulci, which run nearly parallel to the retro-calcarine—namely, the "sulcus limitans superior" above, and the "sulcus limitans inferior" below; these meet together in the pole of the occipital lobe, and bound the area striata at that part. It is only prolonged a little to the posterior lateral surface of the hemisphere around the tip of the occipital lobe. Here it is strictly bounded by the suicus lunatus, which is itself free of the stricte tissue. The area of cortex which it involves is called by Elliot Smith the "area striata." This is the "visuo-sensory area" of Bolton, Campbell, and others, the "primordial visual area" of Flesching.

The structures concerned have been most carefully examined by Campbell, who finds that the special lamination included in the line of Gennari shows its largest dimensions at the forked termination of the posterior calcarine fissure which it surrounds, just reaching the pole of the occipital lobe, and as the length of one or other limb of the fork may be greater or less the extent of the striate tissue will also increase or diminish, not only in length but in breadth and substance. It spreads forward, bounding the retrocalcarine above and below, involving the cuneo-lingual gyri at either end of that fissure. It spreads definitely below, occupying the lingual gyrus, and it passes forward half-way along the lower border of the true calcarine fissure. Above it is well marked at the back of the cuneus, but anteriorly at the angle where the occipito-parietal sulcus leaves the calcarine it has gradually ceased to exist, and it is not found in the cuneal portion of the annectant gyrus at that part. The occipitoparietal sulcus is quite free of it, so is the gyrus fornicatus. There is no striate tissue along the upper margin of the calcarine proper. Both Campbell and Elliot Smith insist that it is only found along the lower margin. On the other hand, the retrocalcarine is extensively and completely surrounded by the stria Gennari both in man and the anthropoid apes. Elliot Smith proposes to call it the 'medial intrastriate sulcus."

On microscopic examination special arrangement is found in the visuo-sensory area. The line of Gennari is seen to be composed of a dense network of fibres of fine calibre mingled with some larger fibres, which run horizontally and There is marked consolidation in the line of Gennari, below it a pale-stained area with the termination of the optic fibres. The external layers of large pyramids are replaced by a layer of curious large triangular or quadrilateral-shaped stellate cells, practically distinctive of this region, and found chiefly along the calcarine fissure; they have strong processes of considerable length which pass horizontally, some of them run obliquely in the fibre plexus. In the deeper parts of the cortex the internal layer of large pyramids is modified by the presence of a layer of pyramidal cells, the solitary cells of Meynert, another important distinctive feature of the calcarine cortex.

Outside the visuo-sensory area is a border about 2 centimetres in width, the visuo-psychic area. It covers the cuneus above, but not the occipito-parietal fissure nor the upper edge of the true calcarine, but it occupies its lower border almost in its whole length. It passes over the back part of the collateral fissure and round the occipital lobe rejoining the cuneus above. The gyrus fornicatus does not seem to be a part of the substratum of vision.

The visuo-psychic region shows peculiarities in the histological structure; fine fibres are numerous, but they are not collected together as in the line of Gennari, nor is there the pallid zone underlying it. The external layer of large pyramids reappears and none of the peculiar stellate cellsremain, but, on the other hand, some of the pyramids are much enlarged into giant cells, with several roots below and one very long-drawn-out process above. These cells are the tributions: it stops abruptly and can be readily traced, and | most characteristic elements of the layer. The large cells

of Meynert are not found. The very great number both of cells and of fine fibres in this area suggests a high degree of functional activity, and through it are probably transferred the impulses, received from the parts around the calcarine, to further districts in the brain where the higher attributes of sight are located.

Dr. F. W. Mott, in his interesting Bowman lecture on the Progressive Development of the Visual Cortex, shows how the width and complication in structure of the cortex gradually increase as we ascend the animal series and how the special cells become more necessary. Thus in the hedgehog, in addition to polymorph and small stellate cells, are found occasional large pyramids. In the rabbit there is a line of Gennari, large stellate cells, and branching pyramids. Ungulates have a well-marked line of Gennari and numerous solitary cells of Meynert. In the cat there are numerous cells of Meynert, but the most striking feature is the depth of the pyramidal layer. These pyramids are also well developed in the cervical region of the cord, and Mott suggests they lie along the volitional path of the executive faculty which is exercised through the fore limb and with the help of binocular vision. The depth of the pyramidal layer increases after birth. Dr. Mott considers that the progressive development of the pyramidal layer in the visual cortex of mammals is associated with an increase in the perfection of binocular vision.

Flesching has shown by preparations of the feetal brain how the development of different parts of the visual areas takes place. He considers that as there are many degrees of functions so the nerve fibres develop as they are required: the sensory found at birth, the motor found soon after birth, and the associated which gradually develop. Thus at birth only a portion of the fibres in the optic-thalamic radiations have acquired their myelin investment. All those that have done so come from the lateral geniculate bodies and they go direct to the calcarine fissure. Those fibres that come from the pulvinar appear to be medullated later in life and to pass outside the immediate limits of the calcarine area. Medullation of the fibres in the cortical areas occurs at different times. Thus an infant very soon sees light, but does not show that it sees an object held in front of it for some weeks, while it takes him as many months to turn his eyes to follow an object held at his side or to stretch out his hand to get it. It is obvious that the highly coordinated work that depends on sight is constantly needing the development of new cells and of association fibres throughout life, and they are far more easily acquired in early life.

The visuo-sensory area along the calcarine fissure is the primary station in each hemisphere for the reception of impressions coming from the retina through the geniculate bodies; around it is the visuo-psychic area to which these impressions are transferred; it occupies the rest of the surface of the occipital lobe, its functions being to elaborate and to interpret. If part of the visuo-psychic area is primarily diseased, there is likely to be a partial hemianopsia complicated by slight peculiarities of vision more or less indefinite, some difficulty in memory of words, some form of letter, word, or mind blindness. When the fibres that go to the temporal region are affected, there may be word deafness, or loss of power in the musical faculty, to recall names, or to read aloud. The psychic cells are associated with the psychoic motor, where the impressions or information gained by sight are transferred for purposes of thought, speech, or action, and these with the emissive motor by which speech and writing are affected. The centres for these latter acts lie adjoining those for the simple movement of the lips and hand.

The various parts of the visual cortex are connected by short association fibres almost infinite in their distributions. Adjoining the occipital lobe and continuous with its lateral portion is the angular gyrus which appears to be a higher visual centre of some importance, probably developed mainly on the left hemisphere. The angular gyrus might be readily associated with the primary visual areas by means of fibres running through the occipital lobe, or with the pulvinar or elsewhere by association fibres.

The central sulcus of each hemisphere separates the motor area (frontal) in front from the sensory area (parietal) behind. The intraparietal sulcus runs upward almost parallel behind the central (inferior and superior post-central); it then turns horizontally backwards parallel to the upper margin of the hemisphere and terminates in the occipital lobe behind. It separates the post-central region of common sensation, and

the superior parieto-occipital gyri from the supra-marginal and angular gyri; these two latter are probably the centre for the recognition of higher, more elaborate forms of sensation and of sight and hearing.

In cases of visual hallucination the angular gyrus is perhaps usually, but not always, affected. The supramarginal may be the seat of mischief or the posterior parietal lobule. A case of scar after injury over the region of the angular gyrus on the right side was associated with epileptiform attacks on the left side, preceded with bright red flashes of light and succeeded by visual hallucinations. Mr. Gould trephined with cure. In a case of Mackwen injury to the side of the head had produced melancholy and homicidal impulses; there was no damage to the outer part of the skull, excepting a slight depression behind the angular process of the frontal, which could not account for the symptoms; no motor phenomena were present. It was discovered that directly after the accident and for some time since the patient had suffered from psychical blindness. The skull was trephined over the angular gyrus, and a portion of the lateral table was found pressing upon the posterior portion of the supra-marginal convolution, a corner of it embedded in the brain. This was removed with relief to his mental condition.

Distant regions are connected with visual areas by long association fibres, some of which are arranged in well-defined bundles. The perpendicular fasciculus connects the defined bundles. superior occipital and parietal gyri above with the inferior occipital and fusiform below, and with the temporal. The superior longitudinal fasciculus joins the frontal lobe with the occipital, and, Mott believes, through the large pyramidal cells of the visuo-psychic area. The inferior longitudinal runs along the outer wall of the posterior and inferior horns of the lateral ventricle, and probably connects sight with hearing, though the fibres may be for projection rather than for association, and connecting the occipital cortex with the optic thalamus. Many fibres connect the neighbourhood of the calcarine with the angular or marginal gyri, and interference with these fibres might produce typical abnormalities The fasciculus occipito-frontalis runs below the corpus callosum external to the lateral ventricle, and connects the convex surface of the occipital lobe with many parts of the frontal. The splenium is the commissure of the occipital lobes, and connects one visual area with the opposite occipital cortex. The occipito-thalamic radiation contains two sets of fibres. The centripetal run towards the occipital cortex to produce vision, and impulses are transferred by the centrifugal from the cortex to the lower parts of the brain to assist the sight by causing movements of the

VISUAL REFLEXES.

The pupil reflex passes through the lower centres, corpora quadrigemina, and third nerve; it is quite unconscious and does not reach the cortex of the brain. But pupil movements are also controlled by impulses centrifugal from the visual cortex through the brachium superius and the quadrigemina.

Many of the simpler and most constant movements that occur in association with sight are automatic, practically reflex, such as involuntary movements starting from the occipital lobes, as in blinking of the eyes on looking towards a sudden light, or to moving objects. Wide movements of the head and limbs are constantly necessary, such as avoidance of obstacles, and become visual reflexes of varying complexity. For them associated fibres run from the visual cortex to the motor centres from which the movements emanate; some of these tracts are in such constant coöperation that the associated movements become a kind of compound reflex action gradually evolved by constant use. Eye movements intimately associated with the most complex mental activities are most of them involuntary and unconscious; consciousness is alone concerned with the result affected.

The visual centres are undoubtedly reached by other afferent impulses than through the eyet all and retina alone. Pupil action and accommodation, and muscle sense produced by movements of the eyes in any direction or in convergence, cause simple impulses towards the brain. Visual judgments also largely depend on impressions from the sense of touch, and as almost every movement of the body is guided by sight the associations around sight are very wide indeed.

When the sight is lost from defects in the eyeball or option nerve almost all other impulses, from hearing, touch, muscle

balance, &c., are effectual in stimulating a healthy visual cortex, and they become increased in influence to the help of faulty sight. But defect in the visual brain is a much more serious matter, and if the sensory area is damaged by disease some part of the psychic area is likely to be affected with it.

EVIDENCE FROM POST-MORTEM EXAMINATIONS.

We cannot overrate our obligations to Ferrier for his early experimental research work on the brain and for drawing attention to the importance of the angular gyrus and of the neighbourhood of the occipital lobe in visual processes, nor to Schäfer, Horsley, and others. Bolton examined in serial sections the occipital lobe in five cases of old-standing blindness and in one case of anophthalmos. In all he found changes in the cortical area throughout the line of Gennari, with marked atrophy of the fibres and of the cells, especially of the large stellate cells. The line was much diminished in thickness but not absent (perhaps from the presence of fibres running from the occipital lobe through the splenium to the opposite of the brain).

A very important paper published by Dr. H. M. Turnbull in Brain (1904) on "Bilateral Loss of Post Central Cortex" described with great detail a case of bilateral cystic degeneration of the occipital lobes and of the neighbouring cortical areas on both sides of the brain, and the consequent absence or deterioration of the optic radiations and optic tracts with the structures associated with them in the sense of sight. The patient died at 24 years of age from severe burns in the London Hospital, January, 1903, under Mr. Moullin. As a baby she was noticed not to follow anything with her eyes—she simply stared straight ahead with them. They were fine eyes and did not squint. She was taken to Moorfields and found to be quite blind. The notes then made were unfortunately not available after her death. She was very peculiar and of uncertain temper. Her powers of hearing, taste, and smell were very good. She could speak with a limited degree of intelligence. Her powers of locomotion and her common sensations were very imperfect. She never showed signs of seeing anything, never examined anything with her eyes, never watched objects moving about the room. After death the brain was removed and most carefully investigated. About the posterior third of each hemisphere was found to form a cyst with thinned walls. The cavity included the posterior horn of the lateral ventricle and part of the middle horn. The cortex involved was that of the occipital lobes (excepting a small portion of the lingual lobule), the cuneus and nearly all the precuneus, most of the parietal cortex, and the angular gyrus. The proper structure of the wide area of the visual cortex and its surroundings was completely destroyed. The posterior part of the corpus callosum was much reduced in size, and the splenium was represented by a mere cord.

(The splenium is the commissure for the occipital lobes, and sends into each a large mass of fibres known as the forceps major, while the tapetum spreads from it over the lateral ventricle. Déjerine had shown that fibres pass in the splenium from the posterior portion of the median surface of the hemispheres from the occipital pole, from the cuneus, the lingual and fusiform convolutions; and Ferrier also found that fibres pass from the lateral surfaces, the external occipital convolutions, and from the angular gyrus to the splenium.)

There was no trace of the fibres of the optic radiations and the retrolentiform portion of the internal capsule from which they pass was extremely atrophied or almost absent. The optic chiasma in front was small and flattened out by pressure from the distended dropsical third ventricle. The optic nerves and tracts were small. (The small middle root of the optic tract was present; it passes to the medial geniculate body, and by the brachium inferius to the inferior colliculus of the corpora quadrigemina and is concerned in hearing.) The lateral root of the optic tract was very small, and the lateral geniculate body through which most of the fibres pass was very much atrophied; no fibres could be traced into it from the retina nor from the brain. The other 20 per cent. fibres of the lateral root was much better defined; it passed upward to the pulvinar and to the superior quadrigeminal body. The pulvinar was only very slightly deficient behind; otherwise the optic thalamus seemed well developed, as were also the quadrigeminal bodies, though somewhat compressed. Though concerned in vision, these parts are not directly associated with the visual

area in conveying impulses for the primary sensation of sight.

A very large number of cases of varying types of hemianopsia have been investigated, but the deductions drawn
between the faulty area of vision involved and the precise
locality of the disease, found in the occipital lobe after
death, are not by any means conclusive or uniform. Many
forms of pathological mischief have caused the changes in the
brain tissues: hemorrhage, gumma, tubercle, softening from
embolism or thrombosis, abscess, tumour, &c. The secondary
area involved around the actual lesion is in many of them
very wide and irregular, and even when thrombosis or
embolism of the calcarine artery or its branches has taken
place the district affected is more or less wide in extent,
and changes are produced not only in parts of the visual
cortex but in the underlying fibres of the optic radiations
and in the neighbouring tissues.

A lesion involving the occipito-thalamic radiation anywhere between the passage of the optic fibres from the retrolenticular portion of the internal capsule or from the lateral geniculate body to the centres in the visual cortex would produce a hemianopsia, varying in degree and permanence according to the position of the fibres involved and the nature of the lesion. Several cases have been published where the mischief has been limited to some part of the optic radiation, without implication of the cortex. radiation fibres, without being the primary seat of lesion. may become affected from without, and a hemianopsia may result by their secondary implications where no part of the visual cortex or tracts is itself affected. But in cases of uncomplicated hemianopsia some primary damage on the mesial aspect of the occipital lobe in the neighbourhood of the calcarine fissure has usually taken place.

Henschen insists that the primary half-vision centre is along the lips and depth of the calcarine fissure, especially of its anterior two-thirds. He considers that the upper and lower quadrants in the visual field (lower and upper parts of the retina) are associated with the structures that occupy the ventral and dorsal areas respectively of the calcarine fissure. The dorsal part of the visual cortex, the cuneal lobe, and dorsal portions of the optic radiations are concerned with the lower quadrants of the field of vision, while the upper quadrants of the visual field are associated with the lingual and fusiform lobes and the ventral boundary of the calcarine fissures and the optic radiations associated with them. In a case of complete hemianopsia under his care there was found in the opposite occipital lobe softening produced by thrombosis. It was confined to the cortex along the calcarine fissure, lying deep in it and giving rise to slight secondary degeneration of the optic fibres beneath.

Wilbrand states that the lower lip of the calcarine corresponds with the upper quadrants of the visual fields. The following is Hun's case.

A man, aged 57 years, was suddenly seized with slight cerebral symptoms. The fields of vision showed a complete left lower quadrant bilateral hemianopsia, the upper left quadrant being also slightly narrowed at the periphery; the charts of vision did not alter for nearly two years. Then he died. There was found on the mesial surface of the occipital lobe a localised atrophy involving the lower third of the cuneus, bounded below by the calcarine fissure and in front by the parieto-occipital.

In other cases such definite division cannot be made out.

A thoroughly reliable case of quadrantic hemianopsia was published by Dr. Beevor and Dr. Collier.

A patient, aged 55 years, was under their observation for nearly two years during which his illness lasted. Careful perimetric observations were repeatedly taken, and a most thorough examination with exhaustive report was made of the brain structures after death. His only general symptoms were numbing of the left hand and arm, severe recurring occipital headache and faulty eyesight, and at long intervals two or three fits. The optic discs were pallid and there was some sclerosis of the retinal arteries. His central vision was 6/9 in either eye; he was completely blind in the upper left quadrant of both visual fields with some general narrowing of the fields. For two months or so before he died his health failed rapidly and his sight got worse. There was found occlusion of the right posterior calcarine artery, with destruction of the visual cortex involving the whole depth of the calcarine fissure, together

with the right lingual lobe and the fusiform lobe below it. The optic radiation was not involved in the necrosis. So far we should expect the defect that was actually found in the visual field. But there was in addition damage to the lower third of the cuneal gyrus and the adjoining retro-calcarine fissure; this latter area, if Henschen's view is correct, should have caused defect in the lower quadrants of the visual field, which in this case were only slightly implicated. Mott, on examining the sections, showed a patch of healthy striate cortex along the upper lip of the calcarine and in the adjoining surface of the cuneus, which he thought accounted for the retention of vision in the lower fields.

Again, by far the greater part of the disease lay in and around the lingual lobe, but the defective field area is not confined to the upper quadrants; it shows definite narrowing of the lower fields as well. Besides, it would seem possible that the upper part of the cortical lesion came later in the disease, after the patient was too ill for further perimetric testing, and when possibly the lower quadrant had become defective from the cuneal disease above.

The cortex lining the calcarine fissure was necrotic, and yet the hemianopsia was not complete. Can the calcarine then be looked upon as the primary half-vision centre? For there was not complete hemianopsia in this case. We must admit the importance of considering not only the amount of mischief done in the cortex, but also the extent to which the radiation fibres are affected. For, as the authors suggest, there may be considerable overlapping in the cortical supply of the various parts of the retina and considerable power of compensation for local damage in the cortex limiting the lesion.

It seems to me probable that the centre for complete hemianopsia lies more anteriorly in the optic radiation near the calcarine proper rather than in the post-calcarine, which was the sulcus here implicated, or else that the optic radiations must be involved when the hemianopsia is complete. And I suggest that the further forward towards the splenium the mischief is, the greater the number of fibres likely to be involved and the wider the hemianopsia, while the more posterior the lesion the more numerous the subdivisions of the artery, and the more localised the area of faulty blood-supply is likely to be and the smaller the defect in the field.

An important means for localising intracranial mischief is the use of the perimeter to ascertain the condition of the visual field and its defects. It is certain that hemianopsia may occur without being necessarily an early symptom of further brain trouble. I have seen a number of patients who with more or less defect in the visual fields have been able to do useful work apparently without discomfort, and who have remained without any other evidence of disease for many years. The common cause in localised cases is, I expect, embolism of some twig of the calcarine artery. The onset is usually sudden, the patient has slight brain disturbance for some days, and then recovers. The obstructed area undergoes atrophy and causes the patient no discomfort except his loss of localised visual area. But hemianopsia may be a part of a spreading lesion, the first symptoms of a thrombosis which will lead to a progressive softening; or of a commencing tumour, which causes pressure upon some part of the visual cortex or radiations, or upon the optic tract.

Trephining made safe by antiseptics may be necessary in primary injuries; for fracture, abscesses, hæmorrhage, and discharging cortical areas in epilepsy. Cysts may be relieved and old gummata removed. Cases of tumour will die if not interfered with, and though some may be malignant and too deep for removal, still others may be on the surface and more casy than might be expected, while, on the other hand, necropsy may show that operation would have saved the patient.

For the study of the blood-supply to the brain structures concerned in vision I would refer to the splendid work of Dr.

Beevor.

The Hughlings Jackson Becture

SPECIAL SENSE DISCHARGES FROM ORGANIC DISEASE.

Delivered before the Neurological Section of the Royal Society of Medicine on Nov. 25th, 1909,

By SIR WILLIAM R. GOWERS, M.D. LOND., F.R.S.,

CONSULTING PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL, LONDON; PHYSICIAN TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN-SQUARE, W.C.

MR. PRESIDENT AND GENTLEMEN,—To deliver the Hughlings Jackson lecture is a task equally pleasant and difficult. Its pleasure and its difficulty arise from the same source. The object of the lecture is to honour the distinguished worker who is still with us by an attempt to promote the researches which have thrown such bright lustre on his name, and, if it be possible, to carry a step further the results he has reached, or at least to provide the means that may enable others to achieve this result. But to make such an effort is to realise its difficulty. Knowledge grows most slowly, for the essential facts are rare, and those already gathered have been made to yield their lessons by the Master himself, beyond whom we cannot hope to go. I fear, therefore, my attempt will involve disappointment to you and to myself.

The subject to which I propose to limit my consideration is the symptoms of epilepsy which are related to the so-called special senses, those of smell, vision, hearing, taste, and perhaps touch; and especially the indications of such epileptic symptoms as are occasionally presented by organic disease. Examples of such epileptic discharges from organic disease, demonstrable in nature and seat, are not common. It is important to lose no opportunity of examining carefully such as are met with.

OLFACTORY.

Anatomically, the special senses begin with that of smell, and the olfactory discharges were the first to receive special study from Dr. Hughlings Jackson, whose analytical observation has exerted a fascinating and inspiring influence on workers in every country. He published a paper calling attention to their complex and instructive peculiarities as long ago as 1866, a paper that was referred to and quoted by Sander of Berlin in an account of a fatal case published in 1874, when he also considered the few cases he had been able to find recorded by previous writers. Dr. Hughlings Jackson returned to the subject again and again in penetrating discussions of individual cases, especially in 1899, in a paper in which Dr. Purves Stewart described six fatal cases that had been published by Hughlings Jackson and Beevor, Hughlings Jackson and Colman, Anderson, Nettleship, Sander, and McLane Hamilton.

Another case was published by C. K. Mills in 1908,² who also added two others described by Linde³ and by Southard,⁴ raising the number to nine. Two cases had been published by Dr. T. Buzzard in 1906³; although in one of these there was no post mortem, the nature and seat of the disease were ascertained by surgery, and it is therefore deserving of inclusion. I have two other fatal cases to describe to you to-night, and I find that Sander, in addition to his own case, quoted two others, one by Lockemann³ in 1861, and another by Westphal⁷ in 1863.

The case described by Dr. Buzzard was a girl, aged 21 years, who was found to have a tumour in and about the right hippocampal gyrus, which had destroyed the uncus and had filled the descending cornu of the lateral ventricle. It had

given rise to a prolonged sensation of a bad taste in the mouth and of a sound of bells in the head, but neither associated with her epileptic attacks. Dr. Buzzard also mentioned that the case, in which the lesion was revealed by surgery, had at first a frequent subjective sound like the loud clang of a piano, accompanied, after a time, by a very unpleasant smell and a keen sense of reminiscence. A glioma was found infiltrating the base of the right temporal lobe, but the operation was not long survived, and no post-mortem examination was allowed.

Lockemann's case was that of a woman, aged 55 years, who died from a malignant tumour of the brain, which extended from the left frontal lobe to the olfactory region, and caused for a time peculiar olfactory warnings described as variable and not unpleasant. That of Westphal was a syphilitic nodule in the pia mater beneath the frontal lobe which had destroyed the right olfactory lobule and caused a very offensive smell as the warning of epileptic fits.

The case which I have specially to describe is that of a man, aged 37 years, who was admitted to the National Hospital for the Paralysed and Epileptic early in 1905, having suffered for three and a half years from frequent slight attacks, of which several occurred daily, often four or five. In these there was first a smell and taste of gas; he could not compare it to any known odour, but it seemed to be something like sulphuretted hydrogen. It caused salivation and eructation from the stomach. The flow of saliva was so abundant that it would run from the mouth and often filled a tea-cup. After the sense of smell he had a slight sense of turning, and if he walked he had a tendency to walk fast, almost to run. Each attack lasted from one to three minutes. Consciousness was not lost. He occasionally had a more prolonged sense of the same odour. He was a well-developed man, and his mental state presented no abnormality. His smell was defective, especially on the right side, but did not seem to be list. There was almost complete left hemianopia. The right half field was restricted in the upper periphery, especially in the right eye. The left optic disc presented papillitis about four disc-breadths in width, but with only slight swelling (2 diopters). The right appeared normal. The only morbid appearance it presented was a little capillary redness in the upper part. Hearing was good on each side. The tongue and throat presented no symptoms. The strength of the left hand seemed a little diminished. Both knee-jerks were brisk, but there was no foot clonus. The left abdominal reflex was slighter than the right. He had only occasional headache, not severe. There was marked tenderness to firm pressure on the right side at the temporal and lower part of the parietal region. No sound could be heard on auscultation

In february he was operated on by Sir Victor Horsley. The right parietal and temporal regions were exposed. The brain was bulging, but no tumour could be seen on the surface or on raising the temporal lobe, but this was firmly adherent to the dura mater near the tip. An oblique incision into the substance of the lobe revealed an infiltrating growth near the anterior extremity, which could only be partially removed in pieces. Hæmorrhage occurred from many vessels, which had to be tied. The operation was borne badly and the patient died a few hours after its completion. At the necropsy it was impossible to discern the precise size and position of the growth in the temporal lobe. It was found to have compressed the chiasma and right optic tract; it was continuous with a mass of similar growth in the white substance of the frontal lobe. The growth was a glioma.

I shall have presently to describe other cases in which the fits were preceded by an auditory warning at first, and subsequently by an olfactory aura, consequent on the descent of a growth towards the apex of the temporal lobe.

Twelve of the cases were so extensive as to have no precise localising value. Of these, 11 were of tumours and 1 of meningitis; another, that of Westphal, had apparently produced the symptom by destruction of the olfactory bulb and tract. There was extensive meningitis in the case of Southard, but there was also an aneurysm, which had destroyed the uncus. In only one case was there an isolated lesion of this structure, a small spot of softening within the uncus, and in this case, described by Hughlings Jackson and Colman, there were no sensations of smell, only the movement of the mouth and jaws which is so suggestive of a sensation of taste. It was present also in the case of

Southard, in which the uncus was destroyed by an aneurysm. Although the symptom is probably a distant secondary effect, and is present in many cases in which there is no evidence of disease in this region, we are almost compelled to regard it as evidence of a gustatory sensation. We must remember, however, that Dr. Hughlings Jackson, in proposing the name "uncinate epilepsy" for these attacks with an olfactory or gustatory aura, expressly disclaimed suggesting more than the general region, traversed by the olfactory roots, as the seat of disease. Where these fibres end, in the various structures they penetrate, remains to be discovered. A putrid odour was occasionally described. Regarding this, cantion is necessary when it does not attend other distinct epileptic symptoms. It may be an isolated manifestation of suppuration in one of the nasal sinuses.

Several features frequently attend these cases of epileptic attacks with an aura of smell, but little can be added to the instructive discussion they have received from Dr. Hughlings Jackson. I may mention that he has called attention to the observations of W. G. Spencer's on the arrest of respiration at the end of inspiration, produced by stimulation of the anterior perforated spot, over which passes the outer root of the olfactory tract and into which some of its fibres pass, as explaining the sense of dyspnea occasionally associated with an olfactory aura. We are reminded of it by some cases of apparently idiopathic epilepsy. For instance, in one a sense of dyspnea seemed to have a nasal origin. The first thing was a stifling sensation in the nose, as if the patient could hardly breathe, followed by a sudden sense of a peculiar momentary bad smell.

The psychical condition which often attends the slighter attacks in cases in which there is an olfactory sensation has been termed the "dreamy" state. There seems to be only a partial impairment of consciousness, or the loss of this occurs so slowly that a distinct recollection is retained of the transient sensations which precede it. The term "dreamy" is often spontaneously applied to the memory of other slight attacks, especially to those in which some definite sensations are experienced. So also with the impression of recurrence, or of precurrence, it might be more accurately termed: the clear conviction that the same feeling has been experienced before. This is a phenomenon of normal brain states, or presumably normal, as Oliver Wendell Holmeshas so well impressed upon us in his "Autocrat of the Breakfast Table" in connexion with Day and Martin's blacking. Much more strange, and at present beyond our power of conceiving an explanation, is the sense of dread, intense and causeless, which has been marked in several

In ordinary epilepsy we sometimes meet with a slighter sensation of smell associated with other deliberate sensory perceptions. In one case the sound of bells, with red and blue lights, was followed by a distinct putrid odour. Another patient always had a peculiarly complex aura, a sensation in the left hypochondriac region seemed to ascend the left side of the thorax in a jerky motion, and, at the clavicle, it became a sound and could be heard as well as felt; when it reached the level of the ear it was like the hissing of a railway engine. Then he suddenly saw an old woman in a brown dress, who offered him something that had the smell of Tonquin beans. The woman then disappeared and two round lights appeared before him, which got nearer and nearer with a jerky motion, and he lost consciousness. warning was always the same, in every detail. Such cases are, doubtless, due to a secondary involvement of an olfactory centre in a discharge beginning elsewhere, and spreading widely but slowly.

AUDITORY.

Organic disease sometimes causes attacks in which the warning is a subjective sound. As might be expected, the cause is generally a tumour of the upper part of the temporal lobe, often subcortical, beneath the first temporal, in which experiment indicates the situation of the auditory centre. But it will be remembered that extirpation of this has never been followed by permanent loss of hearing, neither has this result usually followed enduring destruction of this region by disease in man.

The effect of a tumour in the region was shown by the caserecorded by Dr. Buzzard, which I have already mentioned.

⁸ Proceedings of the Royal Society, 1904, p. 61.

It is noteworthy that the discharge of the centre is often due to a growth in the white fibres beneath. It was so in a remarkable case which came under my notice many years ago at the National Hospital, where the patient was under the care of Dr. Hughlings Jackson, who, with characteristic kindress, has placed the notes at my disposal this evening. The patient was a man, aged 39 years, admitted in November, 1875. He was a painter, but without sign of lead poisoning. There was no history of syphilis. He was left-handed, but had been taught to write with the right hand. For two years he had suffered from fits, about once a week. He had also suffered much from occipital pain, increased by a cough; there was no paralysis. For the first six months there was no warning, subsequently there was an auditory aura. The slighter attacks began by a humming sound in the left ear; those of greater severity by a loud sound like a peal of bells, also to the left. The duration of the sound was about three minutes, and it ceased before the fit began, and just before the sound ended the patient felt a burning sensation in the left external auditory meatus and concha, like the contact of hot coal. The burning sensation then passed down the left side of the neck, and round the back of the neck to the right ear, and also across the forehead. The burning then passed down the thorax front and back, to the leg and foot, where it became a numbness. After the leg, the sensation passed down the arm to the hand. From the onset there was intense frontal pain. The head shook rapidly from side to side, and the eyelids were quivering; sparks also appeared before the eyes, always yellow. At the onset of the burning heat the face became drawn towards the left by tonic spasm, and afterwards there was trembling of the limbs of both sides. In other attacks of the same character the arm was affected by the sensation before the leg, and his description was that the arm seemed as if lying in a bed of stinging nettles. The attacks were always followed by intense headache. When admitted, the optic discs were normal, but in three months optic reuritis slowly developed. Soon afterwards left hemianopia came on, the loss almost reaching to the medial line. The fits he bad in the hospital were less frequent and generally slight. Each was followed by transient weakness of the left side, the only paralytic symptom. His headache improved. After six months he went out and returned at the end of October, 1876. The fits had continued, many had occurred without warning; but those which he had after readmission presented the same aura, the sound of a peal of bells, now followed by pain at the back of the left hand, which passed up the arm to a little above the elbow, and was then felt in the left side of the face. Tingling followed in the left lower leg, and passed up the thigh; then he fell unconscious. The arm was the seat of constant tremor, which was present also in the leg when he was sitting, but ceased when he stood. It began suddenly in June, in a violent form, soon after rising. In the arm it was coarser than in paralysis agitans, and involved all the joints, but was greater in the wrist and fingers than in the elbow or shoulder. A movement stilled it for a time, but it soon returned. The left arm had become distinctly weak; the grasp was 35 with the right hand, and only 10 with the left; the leg seemed strong. The optic neuritis was subsiding, and vision was considerably impaired.

He did not then stay long in the hospital, and the notes are brief, but he was again admitted in October, 1878. Continuous occipital headache still troubled him. Left hemiplegia had gradually developed and had attained a considerable degree. The neuritis had led to consecutive atrophy with still more impairment of sight, greater in the right eye. The left hemianopia persisted. Hearing was noted to be good on each side; smell also was good and equal; taste seemed diminished. His fits had become less frequent and many appeared to have been bilateral. He still had frequent severe occipital headache. occurred after he returned to the hospital; the description of them in the notes never now mentioned an auditory aura. In those that were severe the convulsion was bilateral, but more severe in the left side.

In the beginning of 1879 sight had almost completely failed. Movement of the eyes to the left was attended by nystagmus. Hearing was impaired on the left side, the watch not being heard at all, while it was clearly heard on the right. The left arm was quite powerless; the leg could

still be moved, although feebly, but it was not rigid. The right leg could be moved freely. Sensation was not much impaired in the left limbs. The occipital headache was slighter, but it afterwards again became severe. During the next few months he had an occasional slight fit, and then continuous delirium set in. His wife was dead, but he asserted that he could see her practising prostitution with other patients in the ward. He was almost blind, but when assured that it was not so, his reply was, "Do you think I cannot believe my own eyes?" In August there was alternate convulsion in the right and left side of the face, and then a severe convulsion on the right side. In September the delirium ceased. Smell was noted to be still deficient, but "better on the left side than on the right." Occasionally, however, he had an unpleasant subjective smell "like a strong liniment, almost taking his breath away." On the right side hearing was still good, and on the left the watch could be just detected in contact; there was often subjective ringing. Taste was slow; occasionally a subjective bitter taste was experienced. Sight was practically gone; occasionally he still had subjective sparks to the left. The chest moved well on the right side, very little on the left. He spoke at first in an audible tone, but his voice soon died down to a whisper. The left arm was powerless, with no rigidity, but he complained of a dragging pain in it, and if moved away from his side he could not tell where it was. The right arm was moved freely, but was too feeble to act on a dynamometer. The left leg was powerless but without rigidity, and passive movement caused much pain in it. The right could be well moved. The right knee-jerk was present, the left very slight, and the attempt to obtain it caused pain. There was no foot clonus. He continued in this condition, having a few fits, generally slight. In one, the convenience was in the right arm and slightly in both legs. On Dec. 7th he died suddenly.

Post-mortem examination .- A tumour was found in the right hemisphere, but no morbid process in the left, or in the pons. The growth lay between the optic thalamus and corpus striatum on the inner side, and the convolutions of the temporal lobe on the outer. It was almost confined to the white substance, ceasing about a twelfth of an inch from the grey substance of the temporal convolutions and of the island of Reil, but it had invaded the outer segment of the lenticular nucleus behind the middle of the corpus striatum, and compressed the other segments. It had also invaded the posterior extremity of the optic thalamus for one-eighth of an inch only, and the thalamic substance was softened in an area of a quarter of an inch, just behind the anterior extremity. A tongue of growth appeared at the base between the crus and the uncinate gyrus, which was displaced outwards but not invaded superficially. It had compressed but not invaded the optic tract almost up to the commissure. Behind, in front of the corpora quadrigemina, the growth had invaded the crus in an area the size of a split pea, and thence had passed into the anterior, and slightly into the posterior, right quadrigeminal bodies, but had not crossed the middle The anterior limit of the growth was the neighbourhood of the grey matter of the convolutions of the island of Reil. The highest level it reached was a little above the floor of the lateral ventricle outside it. It had filled the descending cornu and extended beneath the anterior half of the posterior cornu, where it ceased by a rounded end, which was separated by a thin layer of softening from the cerebral substance. Nowhere else was there this separation. This growth was, for the most part, similar to the appearance and consistence of the grey matter of the cortex. An exception was presented by the region between the posterior part of the optic thalamus and the temporal cortex; here it was much firmer, and almost cartilaginous in consistence, yellowish in tint, and it contained several small irregular cavities. It was evidently the oldest part of the growth. The structure of the tumour presented the aspect of a gliosarcoma. It was composed of small oval cells, with a few fibres.

The features of this case are of great interest. earlier fits must have been due to discharges in the right hemisphere, beginning with the auditory centre, as the result of the growth in the white fibres beneath it. Although the cortical centre would be isolated, the discharge would affect consciousness as a sound, and extending to the motor region, which was not isolated, would cause convulsion on

the left side. But before the convulsion the discharge seems to have spread to the centre for common sensibility in the ear, the external auditory meatus and concha, and thence to that for the neck and the trunk, and the left limbs. The discharge in the centre for common sensation in a special sense organ, as well as the special sense itself, is rare, but is occasionally met with in epilepsy. I have not otherwise met with it as a consequence of organic disease. It is, perhaps, intelligible in relation to the auditory centre, because the vibrations of touch stand in so close a relation to those of sound. Lastly, a feature which is difficult to explain is the final convulsions on the right side, for which no explanation could be found in any lesion in the left hemisphere. We must consider that they were produced by the tumour in the right hemisphere acting on the left cortex through the fibres of the corpus callosum.

Dr. Colman, in a very instructive paper on hallucinations produced by organic disease, has published an account of a case of a tumour of the lower part of the central convolutions and the adjacent first temporal on the left side, in which there was the sound of bells in the right ear and afterwards a pleasing hallucination that a musical box was constantly playing. Dr. Colman has also referred to the case of a Jewess, of Odessa, who was subjected by her husband to blows on the head, which amounted to a rough physiological experiment, the results of which were described by Thomaschereski and Stamonowitsch in 1899.10 Congestion of the cranial bone, thickening of the dura mater and pia mater, and inflammatory tissue beneath the latter, with changes in the cortex, were found over part of the right central convolution, the posterior half of the first temporal, the supra-marginal and the angular gyrus. She suffered from convulsions, chiefly left-sided, and persistent auditory sensation on the left side, as well as left-sided visual hallucinations.

Last year, an Italian widow, aged 39 years, was under my care at the hospital with symptoms of a tumour of the temporal lobe, double optic neuritis, headache, and convulsions, some preceded by the sound of a bell ringing on the left, by a very offensive smell, and the vision of a strange woman. Her case was especially fixed in our memory by the fact that she was quite willing that her head should be opened, but she had a profund objection, at first insuperable, to the removal of her hair; she consented only on the assurance that it need only be taken off on one side, and that it would surely grow again. Sir Victor Horsley operated in July. A round encapsuled tumour, subcortical, was found in the temporal lobe; it reached down almost to the uncus. It was shelled out, through an incision, with as little injury to the brain as possible. She had afterwards slight left hemiplegia and diminution of sensation, but she left after two months, rapidly becoming well. Her only subsequent fits were on the day of the operation, and in these the previous aura, the offensive smell, and vision of a strange woman, occurred after the cessation of ten minutes' spasm of the left arm, not before the motor convulsion. These warnings had occurred only for a year and a half, when the fits had been more frequent, but the first fit was when aged 14-a month after her marriage-and they had occurred two or three times a year ever since, with tongue-biting and micturition, quite similar to those of the last year. No family tendency could be heard of. When aged 19 she had a small tumour removed from the breast. The cerebral tumour was thought to be a glio-sarcoma; its structure suggested a long duration, and it may well have been present at the time of the first fit and have caused the convulsions, which were only associated with the auditory and olfactory warnings after it had attained a considerable size.

The reverse is the case with a woman who has just undergone the first stage of operation (on Tuesday last). Her age is 35 years. Fits have occurred for seven years, and were associated, long ago, with a smell of rotten fish and also the sound of a voice, but these have been absent now for several years. Their cause may be learned next week.11

VISUAL.

Discharges in the visual centre seldom result from organic disease; the half-vision centre in the occipital lobe is still the only one generally recognised. Many years ago I

9 Brit. Med. Jour., 1894, p. 1016.

10 Neurologisches Centralblatt, 1889, p. 22.

11 It proved to be a very large cyst in the temporal lobe, connected with the lateral ventricle.

suggested that the symptoms of disease give weight to the experimental conclusions of Ferrier, which indicated that the region of the angular convolution between the parietal and occipital lobes has a visual function. The facts suggest, I think, that this region is connected with both half-vision centres in a complex way, so as to represent the visual function of both eyes, but of the opposite eye to a greater extent than of the eye of the same side. Partial disease of this centre seems to lower its function as a whole. In the hemianæsthesia of hysteria this centre seems to be put out of action, and the effect on vision is well known. Such an hysterical condition is commonly regarded as not worthy of consideration, but functional states are the only evidence we can obtain of some arrangements in the central nervous system; a similar condition of vision may result from an organic lesion.

Some of the preliminary spectra of migraine can be best understood on the assumption that they depend on a slow discharge in this higher visual centre, on the side in which the subsequent headache is felt, especially those that have the form of what is termed the "angled fortification spectrum." The inhibition which accompanies the spectra seems sometimes to be seated in this centre, sometimes in both (when there is a central loss), sometimes in the related half-vision centre. But it is remarkable how very seldom inhibition of the latter forms part of the warning of idiopathic

epilepsy.

I must not allow myself to be led into a discussion of functional affections, but I have to describe some cases of organic disease involving the angular gyrus and causing visual symptoms, cases which seem to afford definite support to the opinion I have put forward. The first case is that of a man, aged 45 years, who is left-handed, and thinks he became so, except for writing, in consequence of an accident to the right hand at the age of about 10 years. He has served in the navy for 20 years, and during that time he had many blows on the head. He denied syphilis, but admitted many risks. Some time in 1902 he was struck on the head by a heavy piece of coal, and in November of that year-how long after the blow he does not know-he had a severe fit, which compelled him to stay in bed five days. He remembered during this time seeing a bright, white light on his left. Subsequently he had slight attacks in which his head turned to the left and there was brief loss of consciousness. In March, 1904, he had three severe fits in one day, with convulsion on the left side and coloured lights to the left. Afterwards slighter fits occurred every few days, until his admission into the hospital in May, and afterwards.

He was a man of considerable intelligence. His smell, taste, sight, and hearing were normal, and so were the optic discs and ocular movements. The left arm was slightly weak; the grasp 75 compared with 90 on the right side, although in general left-handed. The left knee-jerk was the more active, and the plantar reflex was extensor, the right being flexor. The attacks occurred frequently, but varied much in degree. Very careful notes were taken by Dr. Gordon Holmes, who was then resident medical officer. the slightest, the eyes became fixed without deviation. The left side of the face was the seat of slight tonic spasm, and the head turned slowly to the left; consciousness seemed dull for about a minute. In others, in addition, the left arm became rigid, the elbow a little flexed without movement of the wrist or fingers. Smacking movements of the lips terminated each attack, but no sensation of smell could be ascertained, although sometimes he spoke of an unpleasant bitter taste in the mouth.

Many attacks, especially those that were more severe, were heralded by the appearance of several small round objects, seven or ten, just to the left of the fixing point and above it. They were brightly coloured, red on the outside; within this was a zone of blue, the centre being white. They were always the same, and they moved to the left or returned in a series of jerky movements, for five or seven minutes, often longer, after being first seen. During this time his eyes were constantly being jerked towards the left. Almost immediately after the appearance of the balls, dimness developed in the left half of the field, which was slight at first, but rapidly increased in degree until it amounted to complete hemianopia, extending to the middle line, except in a small area round the fixing point. It remained complete until about five minutes after the coloured balls disappeared, when it slowly lessened. At first, soon after the disappearance

of the balls, round markings of the size of the balls could be dimly seen at the place these had occupied. The passing away of the hemianopia was slow; a little dimness still remained half an hour afterwards.

In some attacks there was initial jerking of the eyes to the extreme left, and of the head, by clonic spasm. After a few seconds the spasm ceased, but presently came on again, and these recurrences went on for 20 minutes, each being attended by the noise in the mouth as if the patient were chewing; the arm and leg were rigid, and the arm was the seat of a fine tremor. In it there was complete loss of sensation, to touch and pain, up to 2 inches above the elbowjoint. The right limbs were normal. During this time the patient saw the coloured balls to the left for about ten minutes. When they disappeared the eyes and head could be moved to the right. The tremor of the arm ceased, but was replaced by irregular motion, comparable to athetosis. In a few minutes the loss of sensation had diminished, and extended only over the hand up to 2 inches above the wrist. Consciousness was unimpaired, but after an attack he frequently used wrong words in speaking which bore no resemblance to those he intended to say. Such an attack was sometimes followed by a recurrence, and in this he sometimes completely lost his sight for about a minute, when the half vision returned. Occasionally he felt only the loss of sensation in the arm, which was verified by examination, and there was extreme deviation of the eyes to the left, without the appearance of the coloured balls. The fields were many times separately taken with the perimeter and always found normal. The following note was made of his impairment in speech: "He always understands the nature of objects, and can easily express all his ideas and wants, speaking quite correctly. He understands everything said to him, even when spoken to quickly or in complicated sentences. He can read fairly well, but says it is much more difficult than it was before he became liable to fits; the effort tires him. He can see the words quite well, but has to read a sentence over and over again before he can understand the meaning. His right hand being good, he can write quite well and legibly, but complains of difficulty in expressing his thoughts in writing.

In July the patient was operated on by Sir Victor Horsley. The dura mater over the supramarginal gyrus was found on incision to be considerably thickened. It was removed. No tumour could be seen on the surface, but the pia mater was milky, opaque, and thickened, and the surface of the brain was firm and nodular, and hard to the touch. A horizontal incision was made just above the supramarginal convolution, and the substance of the brain was evidently sclerosed, greyish white, and opaque in aspect; but, though the incision was deep enough to open the lateral ventricle, no tumour was found. In the angular gyrus, posterior to the incision, a firmer patch of sclerosis was found. The opera-

tion was well borne.

One or two fits occurred each subsequent day on the left side, beginning in the face with clonic spasm. Consciousness was not lost. After a week they became less frequent. His mental state was very obtuse. During August there was steady improvement. The wound healed firmly and his fits became less frequent and ceased by the middle of the month. In the middle of September it was noted that his mental state was good and bright, but now and then he seemed to become dull and strange, as though he had a slight attack of petit mal. Hearing was good, and the only defect in sight was a slight peripheral restriction in the left lower edge of the field. The two knee-jerks were equal and the plantars both flexor. Spontaneous speech was quite good. He still complained of difficulty in reading and that sometimes he could not understand what he read, but he read short sentences quite well and showed that he understood them. In reading aloud he made many mistakes, especially with the longer words, and even short ones were often pronounced wrongly. Spontaneous writing was with many mistakes, which he recognised on reading it afterwards. Writing from dictation was very imperfect and long words he said he could not write, and when urged to try he was unable to produce anything like the correct word. He seemed, indeed, to produce some retained visual symbols rather than to translate the auditory symbol into one of appropriate visual character. By the middle of October all trace of

his wife, but still failed in writing from dictation. He was discharged on Oct. 18th, 1904, and has since been heard of as able to pursue his work in Ireland.

The visual phenomena present in the attacks of this patient seem best explained by a discharge of the assumed higher visual centre in the region of the right angular gyrus, a discharge which spread to the adjacent motor centres, or to it from them, and also produced temporary inhibition of the right half-vision centre, which very slowly passed away after the cessation of the discharge. They show how readily the half-vision centre undergoes inhibition, and that sometimes a secondary discharge of the centre in the other hemisphere may result. This has evidently occurred when a hæmorrhage in one occipital lobe has caused permanent hemianopia, but at first complete loss of sight results by the inhibition of the half-vision centre in the other hemisphere, which, in one case I have seen, continued for a week.

Another case has been in the hospital in which a traumatic superficial lesion of the angular gyrus gave rise to fits beginning with a visual aura. The patient was under the care of Dr. F. E. Batten, to whom I am greatly obliged for the opportunity of describing it to you. She is a girl, now aged 9 years, without neurotic heredity, who when aged 3‡ fell down 14 or 15 stairs and struck her head on the stone tiles of the floor below. There was no cut or bruise of the head, and the exact place of the blow was at the time uncertain. She seemed to have no loss of consciousness. Half an hour later she had a fit, with loss of consciousness and twitching of the right side, face, arm, and leg, and she vomited several times during the convulsion. When it ceased she several times during the convulsion. went to sleep, and after two hours woke up seemingly well, and no loss of power was noticed. Similar attacks recurred, and during the following year she had about 40. they ceased, and she was free for three years, until Christmas, 1907, when they returned, and have frequently recurred since in severe form until she came to the National Hospital on June 15th, 1909. In the hospital she had several attacks, differing in severity, but similar to those which had occurred previously. Each began with a bright light in the right of the visual field, and she always rubs the eye with the right hand, not, she says, on account of any discomfort in the eye, but to get rid of the light; the head is then turned slowly to the right and the eyes also deviate to the right. Consciousness is then lost. Tonic spasm then occurs in the right side, followed by clonic movement and twitching of the right side of the face and jerking of the eyes. The duration of the whole is two minutes. Consciousness then returns.

Immediately after the fit sight was distinctly lost in the right side of the field; it was soon regained, although for a time she said she saw objects more distinctly in the left than in the right half. Sensation in the hand was lessened to both touch and pain, and even after a quarter of an hour she complained that she could not feel the hand properly. right plantar reflex was extensor after the fit, the left flexor, and the abdominal reflex was much less on the right side than on the left. In one severe fit there was also some spasm in the left leg. The visual spectrum, which she calls the twinkles," always appears on the right, and she always rubs the right eye. They seem accompanied by deviation of the eyes to the right. She says the twinkles are "like stars. She once said to her father, "They are all colours, green and red and all, and there is a mist over my eye." She generally denies that the spectrum is coloured. Apart from the attacks, her physical condition seemed quite normal. Her ocular movements were perfect and so usually were all reflex actions, including the abdominal and plantar.

On July 6th she was trephined by Mr. Sargeant over the left parieto-occipital region. On exposing the brain the angular gyrus appeared paler and wider than the other convolutions, and in its posterior part was softened. On incision a dark grumous material escaped as well as some pale gelatinous substance. It seemed to be an old blood cyst. It occupied a small region around the termination of the parallel fissure. The wound healed well. The attacks, however, returned and she has been readmitted. They begin with the same visual

aura, but the convulsion is now general.

to produce anything like the correct word. He seemed, indeed, to produce some retained visual symbols rather than to translate the auditory symbol into one of appropriate visual character. By the middle of October all trace of hemiplegia had disappeared. He could write intelligently to

In this connexion I may refer to the case which I have already mentioned of the Odessa Jewess who had a persistent visual hallucination to the left, and the traumatic meningitis on the right side of the brain had involved the whole region of the angular gyrus.

These cases all speak with the same clear significance. It is different from the diminution of the remaining half-field in some cases of hemianopia, which was the evidence on which I relied in my Manual, as justification of the assumption in man of the higher visual function of the region of the angular gyrus. The higher the level of function the more complex its representation may be, and we may hesitate to reject entirely that of which the evidence may still seem imperfect.

LATENT CHOREA: A CONTRIBUTION TO THE STUDY OF SYDENHAM'S CHOREA.

BY REGINALD MILLER, M.D. LOND., M.R.C.P. LOND., PHYSICIAN TO OUT-PATIENTS, PADDINGTON GREEN CHILDREN'S HOSPITAL; ASSISTANT PHYSICIAN TO OUT-PATIENTS, ST. MARY'S HOSPITAL.

In the most important question of the prevention of rheumatic heart disease all are agreed as to the prime necessity of the recognition of the earliest manifestations of the rheumatic infection, and to this end the possible rheumatic nature of such conditions as tonsillitis, "growing pains," and cardiac dilatation has been emphasised by many authors whose views have rightly met with almost universal acceptance. It has seemed to me that for this purpose the study of chorea has been unduly neglected, and it is the object of this communication to emphasise what may be the earliest signs of this type of rheumatism and to draw one or two deductions from the considerations put forward.

At the outset I must offer some defence for the term "latent chorea" with which I have ventured to head this paper. To it there is the obvious objection that in any patient chorea either is present or is absent; nevertheless, it is a convenient name under which to describe cases I believe to be instances of chorea, but which would certainly not be recognised as such. I shall here therefore by "latent chorea" mean such a condition as I am attempting to show to be the earliest form of nervous rheumatism, and by "chorea" the well-known disease with (amongst other symptoms) its disorders of movement, characteristic and obvious. We may perhaps with advantage study first the common symptoms which are seen in a case of chorea, noticing especially how they might be expected to appear in their slightest and earliest forms. They may be divided into motor, mental, and atonic.

The motor symptoms consist of the perpetual, irregular, and purposeless movements of the limbs, which have been described as those of "exaggerated fidgetiness" (Sturges). In addition there may be noted incoordination, due in part, I think, to cerebellar involvement, which assists in rendering voluntary movements clumsy, and in bad cases quite futile. In the trunk there are seen squirming movements and often irregular and incoördinate action of the respiratory muscles, so that the breathing may be in turn thoracic, abdominal, or normal in type. Long-drawn sighs, such as are heard in nervous women, are very common. In the face the movements show themselves, as they must, in various emotional expressions, such as those of pleasure, dislike, fear, or surprise, which flit across the countenance. These may not in severe cases, as far as can be gathered, indicate any corresponding emotion on the part of the child, but often in the slighter forms of the disease they do express (or rather over-express) the mental attitude of the moment. In addition there are movements of the jaw, tongue, and lips which may cause the familiar choreic "clucking." Pupillary changes are not uncommon and are of some interest to us here. Dr. F. Langmead 1 has described hippus, inequality, and eccentricity of the pupils, and to these may be added irregularities in shape. As I have seen them these are usually found in the early stages of chorea. The displacement of the pupil, in my experience, is always upwards and inwards. Dr. Langmead pointed out that they were seen

in cases of chorea, but also, although less frequently, in patients suffering from acute rheumatism but not diagnosed as instances of chorea. It must, however, be acknowledged that in nervous but non-rheumatic children these pupillary abnormalities are sometimes found, and I cannot help regarding them as evidence of nervous instability rather than of any type of rheumatic infection.

Reducing these motor phenomena of chorea down to their slightest forms, such as we might surmise to be present at the very outset of the disease, we should expect to find general fidgetiness only slightly exaggerated, clumsiness in voluntary movements (especially in the finer ones of the fingers), and unnecessary and excessive emotional movements of the face. To these might be added, perhaps, abnormalities of the pupils and the occurrence of occasional sighing respirations of a nervous type. All of these symptoms might be taken to denote merely an extremely neurotic child.

Of sensory changes in chorea I have not found more than a trace. Pharyngeal anæsthesia, the only one I have looked for often, I have noted but twice. Considering how comparatively common this is in neurotic young adults, I had expected to find it in chorea more frequently than I did. Its absence may perhaps be explained by the chronic tonsillitis and general faucial injection which are so usual in choreic patients.

The mental symptoms of chorea are of great importance, and it is not too much to say that they have not received the recognition that is due to them. They are so constantly present and so much a part of the disease that in many ways chorea might well be looked upon as a mental rather than a motor disease. Yet the mental side of the disease has been so neglected that some authors have gone the length of describing a condition which they term "hemi-chorea." With the severe forms of choreic insanity, such as a raving delirium, agitated melancholia, dementia or coma, we are not here specially concerned. What I wish to emphasise particularly are those slighter types of mental perversion which are seen in one form or another in all choreic children. These are mental depression, excitability, emotionalism, inattention, loss of memory, or signs of diminished control as shown by outbursts of passion, unnatural fear, uncontrollable laughing or crying. Often indeed, if the history of the onset of chorea be carefully traced, it is found that such symptoms as these are noted prior to the development of definite movements. As a rule early in the disease the mental attitude is one of depression, while during convalescence it becomes one of exaltation. This will be referred to later in the study of the nervous symptoms (latent chorea) in cases of acute and convalescent rheumatism. In their slightest forms, therefore, these symptoms of chorea would appear as those of mental instability as shown by excitability, fretfulness, inattention, and attacks of passion or crying; such symptoms as might be found in a neurotic, spoilt, but nonrheumatic child.

The atonic symptoms of chorea, paresis or paralysis, are usually present only in the severer forms of the disease and, as a rule, are late in their appearance. Sometimes the paralysis is so marked and accompanied by such rapid wasting as to suggest that the anterior horn cells have been attacked by the infection. I mention this because chorea is so often spoken of as cerebral rheumatism, whereas it may quite possibly be a disease of the whole of the central nervous system in which involvement of the cerebrum gives rise to the earliest and grossest perversions of function. It is obvious that the atonic symptoms in their lesser forms will not be recognisable as choreic, and thus are of no aid to us in approaching the disease from our present standpoint.

Before passing on I must make mention of some of the other signs of the rheumatic infection, particularly as they occur in cases of chorca. Over tonsillitis, "growing pains," muscular rheumatism, and subcutaneous nodules we need not pause; their significance is well appreciated. Arthritis rarely co-exists with well-marked choreic movements as has long been recognised. Perhaps this is owing to the stimulus to complete motor control set up by a painful joint.

to complete motor control set up by a painful joint.

The heart, as has been taught by Dr. D. B. Lees, shows dilatation as its earliest response to active rheumatism. This is only to be detected by careful percussion of the deep cardiac dulness. In addition the pulse is quickened and the heart excitable. Reduplication of the first apical sound is of some interest: it is not uncommon in dilated hearts and

in those of children who are nervous under examination, and where these two factors are both present, as in chorea, it is so common as to be almost the rule. Usually it passes off after a few days' rest in bed. Irregularity of the heart is very frequent in chorea, but is not so common as is the reduplicated and rather slapping first apical sound. The pulmonary second sound is usually augmented and frequently doubled. In the earliest stages of cardiac dilatation there is no systolic bruit at the apex.

Anæmia is the rule in all rheumatic infections, and it is of interest as to some extent it is an index to the progress of the case. It is very prone to remain in spite of treatment by iron should the infection be quieted but not destroyed. It is frequently seen associated with a rather characteristic pink flush on the cheek. Pain in the epigastrium or in the left side of the chest is a symptom often found in rheumatic children, and I have seen it so severe as to be the cause of the child's visit to hospital. It may occur after food but often is independent of meals. Epistaxis is not uncommon in rheumatic children with slight cardiac affections, as Dr. Sidney Phillips has pointed out.

Headache is an interesting symptom. It is, of course, a common associate of anæmia, but in children is more often than not rheumatic in origin. Goodhart 2 states that in 33 cases of headache 23 were of rheumatic stock. commonly this symptom is seen in the early stages of chorea, as Dr. G. F. Still has noted, and so may be regarded not only as rheumatic but as evidence in many cases of an early intracranial infection. It will be remembered that Dr. F. J. Poynton and Dr. Gordon M. Holmes 1 have found vascular engorgement of the pia-arachnoid among other changes in chorea. Thinking that the headache might be due to meningeal ædema, for an excess of cerebro-spinal fluid is usually present in chorea, I tried the effect of calcium lactate as suggested by Sir A. Wright. The symptom was, however, completely unrelieved by this measure, while as a rule it is easily amenable to treatment by sodium salicylate. It is important to recognise that while headache is a frequent result of rheumatism in children, it is rarely produced in them by the salicylate group of drugs.

Sweating of the palms of the hands is very constantly seen in children with any form of rheumatism, but to a less extent is not uncommon in others as well.

I have described in some detail symptoms that must be familiar to all who have studied rheumatism in childhood, partly because any emphasis that is laid upon the fact that chorea is not a disease of the motor system alone is not amiss, and partly because in the delicate task of tracing so composite a clinical condition as this to its earliest manifestations it is necessary to put clearly what are the symptoms that might be expected to be present. It will be seen that I have for the most part omitted the occasional and rare phenomena and have referred to those which are seen if looked for in case after case.

We may expect, then, that a patient showing the earliest signs of chorea would appear to us in somewhat the following light. The child would be pale, fidgety, and in the finer movements of the limbs clumsy; he would be nervous, easily frightened and upset, affectionate but passionate when crossed, excitable but readily exhausted, unable to concentrate his attention on anything for more than a moment, and hence getting into trouble at school, particularly over his The heart will almost certainly be dilated and excitable, with reduplication of the first sound at the apex and possibly irregularity of rhythm. The hands will be moist, and the pupils may show various abnormalities. Headache and pain in the left side or epigastrium might also be present. On inquiry there would probably be obtainable a history of sore-throats or growing pains, or of a strong rheumatic taint in the family. In addition there might be symptoms that I have not yet mentioned. From the general nervous instability as seen in the earliest stages of chorea may arise many so called functional nervous disorders, such as disturbed sleep, night terrors, somnambulism, acquired enuresis, habit-spasms, lienteric diarrhoea, and the like.

I may now proceed to describe how this condition of mental and physical ill-health, which is rheumatic in origin and which I have termed "latent chorea," is met with in children. It may be seen in three groups of cases, and I give them, not in order of their importance, but in that in

Goodhart and Still: Diseases of Children, seventh edition, p. 661.
 Common Disorders of Childhood, p. 458,
 THE LANCET, Oct. 13th, 1906, p. 982.

which they are most conveniently studied. These are (1) in children with obvious acute rheumatism; (2) in children convalescent from rheumatism and chorea; and (3) in children without any very obvious rheumatic symptoms.

1. Latent choren associated with acute rheumatism. - Children with acute rheumatism of the joints, muscles, or heart show as a rule that the nervous system has not escaped. I have heard the saying attributed to a physician eminent among those who study the diseases of children that "nearly all rheumatic children have chorea." Certainly this is so if chorea is recognised in its earliest forms. If it is taken to be a disease of disordered movements only, and these are tested for by the coarse method of making the child hold its hands out straight in front of it, then the disease cannot be said to exist in all rheumatic children. A more delicate test for these movements is required. Watch how the child fidgets as one approaches the bed, how jerkily the hand is withdrawn from under the bedclothes to shake hands, or how the clumsiness in action is shown as the child pulls up its bed-dress for its chest to be examined; in such ways the traces of choreic movements are clearly seen. Often, indeed, a definite attack of chorea can be watched developing out of such slight signs as these. Another test which I have found of use is that noticed when looking for pupillary changes - namely, the child's inability to keep its eyes fixed on an object for more than a second or two. As Dr. Langmead pointed out, abnormalities of the pupils are not uncommon in these children. On the mental side also traces of chorea are quite evident. How depressed are children with acute rheumatism and this in the absence of pain. When admitted to hospital their trials are no greater than those of other children, but their unhappiness is much more severe. Often they can be found crying quietly with long convulsive sobs, the very picture of misery. mental depression has often been noticed in cases of acute rheumatism, and has been attributed to the treatment by salicylates. But I have seen it many times where no such drug has been used, and I have seen children entirely free from it yet taking between 300 and 400 grains of sodium salicylate per diem, and am convinced, therefore, that this symptom of mental depression has, as have anæmia, cardiac depression," and others, been erroneously ascribed to the treatment instead of to the disease. Salicylate of soda will, as Dr. Lees teaches, depress a child if allowed to produce nausea or vomiting, but not otherwise. In adults with acute rheumatism a feeling of intense misery is not seldom present and is not always attributed by the patient to pain. That it is not so marked as in children is explicable on the grounds that the nervous system is more stable in adults than in young subjects and that in children all bacterial infections tend to become more generalised than is the case in adults.

At a Christmas entertainment in a children's ward I had once an excellent opportunity of noticing the nervous instability caused by rheumatism. One of the performers entered the ward dressed in a "property" monkey's skin. Most of the patients were delighted, but from some came immediate shrieks of terror, and I noted that those frightened included not only convalescent cases of chorea, but children with joint or cardiac rheumatism.

The recognition of latent chorea in cases of acute rheumatism adds another link to the strong chain of evidence binding rheumatism and chorea together as the result of one and the same infection.

2. Latent chorea in convalescence from acute rheumatism and chorea. - During convalescence from acute rheumatism the signs of latent chorea are somewhat different from those just described. The main change is in the mental condition of the child, the morbid depression is succeeded by an unnatural mental exaltation. The convalescent rheumatic child is a very delightful little person and in a ward is everyone's favourite. (I think no one will deny this.) He is affectionate, obedient, intelligent, and quick; his wits are, in fact, considerably sharper than those of most children. His shyness has gone and he is now willing very quickly to become your friend. He is very prone to become overexcited at play and has to be looked after on that account. He is apt to take liberties with you, and in his excitement may be very rude in a guileless way. A word from one in proper authority, however, quickly subdues him and may reduce him to tears of penitence; I do not think I ever saw him seriously punished.

In addition to these signs of mental instability the slight

motor symptoms already mentioned are still present, but as the initial depression wears off a new facial movement makes its appearance. This is the quick smile of welcome seen on the approach of a visitor; pleasant enough in its way but far from convincing, a veritable "society smile." In cases of chorea it is often seen and indicates, I think, practically no emotion of pleasure, but during convalescence it does express in an exaggerated way the feeling of pleasure. It is very characteristic.

A patient recovering from chorea passes into exactly the same condition, and to one who has trained himself to recognise at sight the slighter forms of chorea it is often impossible to distinguish at a glance between the child who has rheumatic synovitis or slight heart trouble and one who is getting well from cherea. Lastly, under this heading comes an important consideration. This latent chorea of convalescence may depend on nerve-cells which have been damaged by a rheumatic infection which is passed and gone, but on the other hand—and this is specially to be feared where there are persistent anæmia and a regular slight nocturnal rise of temperature—it may be due to a still smouldering infection, one that is damped down but not destroved.

3. Latent chorea without obvious symptoms of rheumatism.—
It is to this class that I wish to call special attention, for by
the failure to recognise it and its rheumatic origin we may
lose a valuable opportunity of preventing the severer forms
of heart disease.

Children suffering from this form of latent chorea may be brought to the doctor for various complaints. For the most part these are of a slight and indefinite nature. The mother may complain that the child is out of sorts, is languid, will often refuse to touch its food; in her own phrase, "I don't know what to make of him." Headache is a common symptom, and for this, I should imagine, these children not seldom find their way to the ophthalmic departments of hospitals. The mother may volunteer the fact that the child is very nervous but, as a rule, inquiry has to be made if there has been any change in the child's temperament, when it will be found that he has become excitable, fidgety, irritable, passionate, and timid. The patient may have become too frightened to sleep alone or to cross a street. Sometimes the child's pallor attracts the mother's attention, or it may be that symptoms referable to the cardiac dilatation, such as the feeling of being always tired or of the feet being too heavy to lift, cause the visit to Fidgetiness is rarely in these cases the chief complaint, but on inquiry the mother has usually noticed it, and may say that the boy is no longer able to play quietly by himself or the girl to sit at her sewing. In addition, the voluntary movements of the finer sorts have become clumsy. I have seen in these children the marks of needle pricks all over the three middle fingers of the left hand, while in an ordinary little girl who sews they are confined chiefly to the inner surface of the index and to the tip of the middle finger. Their mental fidgetiness is often shown by the fact that although previously good at school they have lately got into disgrace over their lessons, particularly their sums, and may even have been threatened with degradation to a lower class.

On the other hand, more definite symptoms arising from the nervous instability of these patients may cause the child to be taken to the doctor. The most common of these are talking (often doing sums) during sleep, difficulty in getting off to sleep, night terrors, somnambulism, acquired enuresis, lienteric diarrhœa, or habit spasms. These cannot be regarded as part of the chorea, but are rather of the nature of complicating symptoms; the chorea causes the nervous instability, which in its turn is responsible for the appearance of this group of disorders. The appearance in rheumatic children of such conditions as these has been noted by many authors.

The diagnosis of this type of chorea is often suggested at sight, partly by the peculiar pink flush of the patient's cheeks and partly by the general deportment of the child, the fidgetiness, the smiling, and the generally unbalanced nervous state. Such an impression needs careful confirmation by means of the examination of the patient's symptoms and physical signs. Of first importance is the question of sore-throats and growing pains, while headaches are of very constant occurrence. In 16 consecutive cases of latent chorea of this type I noted sore-throats in 13, growing pains

in 9, and headaches in 11. Inquiries should be made into the family history for evidence of rheumatic fever or chorea in the parents or, a matter of greater importance, in brothers and sisters. As might be expected, an inherited neuropathic taint can often be traced. In a neurotic child the earliest symptoms of a mild rheumatic infection are likely to be those referable to the nervous system. Dilatation of the heart is in favour of a rheumatic infection, for this is the most common cause of such a condition in children.

We have, then, to decide in any particular case if the condition is one of latent chorea or is simply an expression of nervousness in a neurotic but non-rheumatic child. A nervous child may show a considerable amount of fidgety movement—a miorokinesis, Dr. F. Warner has termed it, and may be emotional and anæmic and may show slight dilatation of the heart. The symptoms of latent chorea can, as a rule, be distinguished from this state with fair ease. They are of recent origin, the movements are rather different in type, and are associated with clumsiness in the finer voluntary movements, as in sewing. The impossibility of getting the child to fix the eyes on an object for more than a second or two is much more characteristically present in cases of latent chorea than in neurotic but non-rheumatic children. But sometimes it is difficult to decide between the two conditions; as Dr. Still's says, a nervous child "manifests a general fidgetiness which is easily mistaken for a slight chorea." Where such a difficulty arises, the question can usually be settled by inquiry into the matter of sore-throats and growing pains. Where these are, or have been, present, and especially where they are associated with dilatation of the heart, headaches, pain in the left side or epigastrium, moist hands, and where there is a marked family history of rheumatism, the diagnosis of latent chorea becomes increasingly probable. The diagnosis is not to be settled by the presence of any one of these points but by the coexistence of several of them.

I do not wish to suggest that all children who are nervous, fidgety, and pale, and who show slight dilatation of the heart, wet hands, or pupillary abnormalities are the subjects of a rheumatic infection; in many such there is no evidence of this disease to be traced. But it is the main object of this paper to emphasise the fact that just such a condition of ill-health and nervous instability may be due, and in London is very commonly due, to a latent chorea. It is then a matter of some moment that the physician, confronted with a child suffering from various nervous symptoms, should bear in mind the frequency with which such disorders owe their origin to a rheumatic infection; for, to transpose Dr. Still's words quoted above, a child with a slight degree of chorea manifests a general fidgetiness (with others signs) which is easily mistaken for simple nervousness.

It might be suggested that what I have termed latent chorea is due to a rheumatic toxemia, while chorea, fully developed, is due to a rheumatic infection of the central nervous system. While this may or may not be the case, it is a small point beside the important one of the recognition that the condition is rheumatic.

Lastly, the association between rheumatism and "nervousness" has been recognised for many years until it has become to be vaguely held that the infection is particularly prone to attack children of a neurotic temperament. It appears to me, however, that this association is much more properly explained for the great majority of cases by regarding the nervousness as a result of a mild and unrecognised infection. Given the infection, the symptoms of chorea, latent or fully developed, are more prone to appear in a neurotic than a normal child.

Conclusions.—1. That (rheumatic) chorea declares itself first by symptoms significant of general nervous instability. 2. That in dealing with children suffering from nervous disorders of many kinds special care should be taken to exclude the possibility of their having originated from a slight rheumatic infection. 3. That the well-known association between rheumatism and nervous instability is not to be explained by considering that the infection is specially prone to attack neurotic children, but by regarding the nervousness as in most cases the outcome of an infection already present (latent chorea). 4. That the mental depression and headache in rheumatic children are usually to be attributed to the disease and not to its treatment by salicylates. 5. That

the recognition of latent chorea, in children suffering from obvious acute rheumatism affords strong evidence that chorea is a rheumatic condition.

Queen Anne-street, W.

NOTES OF A CASE OF X RAY ULCERS CURED BY HILTON'S METHOD.

BY AGNES F. SAVILL, M.A. St. And., M.D. GLASG., M.R.C.P. IREL.,

ASSISTANT PHYSICIAN TO ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, LEICESTER SQUARE.

A MARRIED woman, aged 30 years, consulted me at St. John's Hospital for Skin Diseases on Feb. 2nd, 1909, complaining of intense pain in two ulcers situated on the left shoulder and upper arm. The ulcers had appeared after prolonged treatment by X rays for scleroderma, and the pain was so severe that she had not slept for over an hour at a time for nearly two years.

The patient was a sensible woman, able to give a clear account of her illness and the progress of her symptoms. Just after the birth of her first child in 1898 she had pain in the left breast, and a few weeks later she noticed the skin on the inner side of the breast had a white mark, which increased in size very slowly and spread over to the sternum. About four years later (1902) the left shoulder and upper part of the arm became affected similarly, and during the following year the whiteness and thickening of the skin gradually extended to the forearm. In 1903 she sought advice at one of the large hospitals in Great Britain and treatment by X rays was ordered. Six months later the disease appeared on the outer aspect of the left thigh, and X rays were administered to that patch also. Some time later she became aware that small patches had appeared on the back and on the chest under the left arm, and in the winter of 1908-09 patches appeared on the left side of the neck just above the clavicle.

History of the X ray treatment and its results.—The treatment was administered almost daily for a period of two years, from 1903 to 1905. The left shoulder was exposed to the rays for five minutes, the lower part of the arm for another five minutes. During this treatment of the arm she was in the habit of sitting with the elbow flexed, the hand resting on the shoulder, with the thumb tucked in under the first finger. The breast and the thigh were also exposed for about five minutes each. Thus the daily treatment lasted altogether about 20 minutes. Sometimes there was a degree of reaction, when she was given a week or two of rest until it had subsided. The reaction consisted of redness and soreness, not severe, and it occurred only on the upper left arm and shoulder, never on the breast or thigh. She believes that towards the latter part of the treatment it occurred about every six or eight weeks, and usually lasted only for about one week. In 1905, however, a very severe reaction occurred, which extended down as far as the elbow, and the left side of the face and the first and second fingers of the left hand also were affected. She decided not to have any more treatment. A year or so later she left that town and came to reside near London and was therefore unable to seek advice from her former medical men for the conditions which ensued. When the inflammation had subsided she noticed two small "pimples," one on the left shoulder, one about 2 or 3 inches lower on the upper arm. These "pimples" inches lower on the upper arm. These "pimples" remained troublesome for two years (1905 to 1907); always catching in her clothing as she dressed and undressed and were very tender. They had a hard scaly top, and later became red and swollen around. About 1907 the scaly tops used to come off frequently, grow again, and again fall off. Then the tops failed to reform, and open sores were left beneath. A little lower down on the arm was a smaller pimple which, presumably, was not so much exposed to friction, because the patient's attention had not been drawn to it; the importance of this lesion will be referred to below. The two ulcers slowly increased in size and became intensely painful. The upper ulcer was never larger than the size of a shilling, the lower became as large as a fiveshilling bit, and was, she thinks, about ½ inch deep; at no time was there much discharge. For two years (1907-09)

she was unable to obtain relief sufficient to obtain more than an hour of sleep at a time. She sought medical advice in various quarters, and tried innumerable remedies in vain. At last she discovered that carbolic fomentations (1 in 100) gave more relief than any other application. Even with this she was obliged to rise up in the night every hour to apply a new dressing, and her whole life, day and night, was devoted to devising some method of alleviating pain for an hour or half an hour at a time. The pain was steady, with occasional sharp darts, and extended from the ulcers up to the spine; she indicated a position on the spine extending 3 inches below the second dorsal vertebra.

Condition when seen in February, 1909. - When the patient consulted me at St John's Hospital there were two ulcers, one on the rounded part of the left shoulder, the other 2 inches lower on the outer aspect of the arm. Both were about the size of a shilling, the lower slightly deeper, about one-third of an inch, with irregular raised margins and clean red bases. Two inches nearer the elbow, in a line with the ulcers, was a hard raised papule with a scab. This was picked off a few days later and revealed a small ulcer which in three days time enlarged to the size of a threepenny-bit. The patient explained that the upper two ulcers had begun in a similar fashion and she had not observed when the third nodule first made its appearance. The ulcers were situated on a band of thick sclerodermatous tissue which extended down as far as the middle of the forearm. This band varied in breadth from 4 to 1 inch, and was surrounded by an area of white atrophied skin over which coursed large telangiectases. The first and second fingers of the left hand (which, as described above, had also been exposed to the X rays) showed signs of chronic X ray dermatitis of a mild degree—slight atrophy and telangiectasis, with brittleness of the nails, and the left cheek presented a slight mottling which was not seen on the other cheek. Similar atrophy with large telangiectases existed on the breast and thigh, the parts which had been exposed to the rays. Patches of morphoea (localised scieroderma) were present on the back and chest; some of these were white and thickened, some were pigmented, with a purple surrounding area, such as is frequently met with in association with morphoea, but none of those untreated areas had the marked degree of telangiectasis present over the areas which had been exposed to the X rays.

Treatment.—After trying cocaine and other analgesic applications a week without any effect I asked my colleague, Dr. Alfred Eddowes, to see the patient and to take her into the hospital if he considered that an operation would yield good results in such a case. Dr. Eddowes considered that the only possible method of giving relief to the patient was to divide the nerves just before they entered the ulcerated areas. Accordingly, on Feb. 18th, 1909, he operated. A semicircular incision, about one inch deep, was made above each of the three filters. Another slightly shorter semicircular incision of the same depth was made across the centre of each ulcer. Free bleeding was encouraged; and the gaping wounds were stuffed with aseptic gauze and a fomentation applied. The gauze remained in for several days; it was left in situ until the granulation tissue, swelling up from the bottom of the wounds, pushed out the gauze before it. The gauze, therefore, was not removed until nature herself rejected it, and the wounds healed up slowly with abundant granulation tissue. The natural healthy discharge was not washed off with antiseptic lotions; a non-irritant boracic acid ointment with yellow paraffin basis was applied. The operation had an immediate result for the better on the patient's condition. Although a sleeping draught of chloral hydrate was administered for another week the patient stated that on the evening after the operation the pain had entirely altered in character, and she so rapidly improved that at the end of the week she was able to have a good night's rest without the administration of any hypnotic. During her residence in hospital injections of fibrolysin were given to bring about absorption of the extremely hard sclerodermatous condition of the arm. When the patient was discharged from the hospital after three weeks' residence the ulcers had almost healed up and were completely free from pain. Since that time (March) she has attended more or less regularly, at fortnightly intervals, the out-patient department of the hospital. Although the operation had cured the pain and the ulcers had at once started to close complete healing did not take place for several months; a tiny nodule remained in the centre which refused to be completely covered with healthy skin. Many different lotions and ointments were tried, but the only application which did not set up discomfort was boracic ointment made up with yellow vaseline. It must be remembered that these ulcers were situated on sclerodermatous tissue, and the unhealed nodule was in the centre of the thick waxy band of diseased skin. The injections of fibrolysin begun during the stay in hospital were repeated at each visit to the out-patient department with the object of softening the thick sclerodermatous parts. The result of the injections was satisfactory; all the thickened parts became softer and thinner. By October, 1909, the upper two ulcers were completely healed, but the third still presented a small nodule, which did not heal till November.

Remarks.—The case is of interest in that it demonstrates how certain forms of X ray ulcers may be cured, and the excruciating pain relieved even after two years' suffering by the old method described by the late Mr. John Hilton. In his well-known work "Rest and Pain" he mentions an exceedingly painful and obstinate form of ulcer. He believes the condition was due to the presence of an exposed or injured nerve termination near the surface of the ulcer. The pain was relieved and the ulcer cured by passing a pointed bistoury in such a way that the nerve was divided between the spine and the painful part in the ulcer. Very little is at present known of the condition of the nerves in X ray dermatitis, and as no histological examination was made of the ulcers in the present case it would be useless to formulate any theory as to the cause of her pain. In spite of the fact that the ulcers appeared on a part of skin affected with scleroderma there can be no doubt that they were due to the frequent short doses of X rays. In a letter to the British Medical Journal (September, 1906) Mr. Hall-Edwards describes his unhappy experiences, and it will be noticed that his description of pain corresponds with that endured by the patient in the case above described. "I have not experienced a moment's freedom from pain for more than two years. The pain is of a neuralgic character; it never ceases, and is intensited from time to time by sudden stabs and jumps." So far as a have been able to find in the somewhat scanty literature on the subject of the treatment of these chronic ulcers, curettage and skin-grafting, or excision, have been the only successful methods of dealing with them, and amputation when they begin to take on a malignant character. I hope the above brief notes may be of use to sufferers who have tried local applications in vain.

Harley-street, W.

ACTION OF CRYOGENINE ON PHTHISICAL TEMPERATURE.

By J. E. GORDON, M.D. EDIN., MEDICAL SUPERINTENDENT, DEVON AND CORNWALL SANATORIUM.

Most recent advances in the treatment of the thermal state in pulmonary tuberculosis have a tendency towards dispensing entirely with the assistance of drugs. The absolute rest practice for the lowering of the temperature has very much to commend it, and in an institution where it can be efficiently promoted very satisfactory results are obtained. The "spoon-fed and bed-pan" patient, however, is by no means always a possibility, and notably is this the case in general practice where the means of the patient do not always permit of the luxury of a nurse. In certain sanatoriums for consumptives—for instance, in those which are run without a nursing staff—absolute rest for any length of time, the view being the lowering of temperature, cannot be insisted upon. Absolute rest not being possible, the question is, then, what are the best means to be adopted to influence a thermic depression? Of course, the patient is put to bed, and if fever is high sponging may be resorted to, and an acid mixture, or aspirin or phenacetin, may be ordered. This may be all that is necessary, and the temperature comes down to remain down.

In the case of obstinate temperature the ordinary pharmacopicia of antipyretics may be tried, one after the other, without result, or merely with transitory effect. The continued course of the high temperature of acute disease, besides discouraging the patient, causes grave physical distress, and it is imperative that the practitioner should find the means to control it. The usual remedies having been tried and found wanting, the exhibition of the little-known drug (in this country) cryogenine may result favourably. I am prompted to speak kindly of cryogenine, as, from a long experience of it, I have found it to act in many instances where the more notorious antipyretics have failed. Cryogenine has been considerably mentioned in continental medical literature. In regard to its composition the following formula is given:—

 C^6H^4 $CoAzH^2$ $AzH - AzH - Co - AzH^2$.

The introduction of the group AzH — AzH — Co — AzH-into the aromatic nucleus is stated to endow this drug with its antipyretic properties. "Az" is the French symbol for azotum. Cryogenine is, in short, a semi-carbazide.

Cryogenine being a powder, the simplest way to administer it is as such, or in a wafer or cachet. As to dosage, I have never exceeded 8 grains. For adults 5 grains is a suitable quantity to commence with, and often it will be found unnecessary to exceed this amount. Cryogenine is said to possess very little toxicity. While the doses I have mentioned are smaller than those prescribed on the continent, I have never found any ill effects to attend their continuous administration twice daily for a fortnight or three weeks. Far from this prolongation having a deleterious effect on the organism, the patient will often confess to a sense of well-being while under the influence of this remedy. It is, however, not advisable to continue cryogenine for too long, as constant use predisposes to immunity. The method of dosage on the continent is to begin with a large dose, 50 to 120 centigrammes (about 8 to 19 grains), and, the thermic depression having thus been attained, to continue in decreasing doses at intervals of 24, 36, or 48 hours as necessary. Children and debilitated individuals, of course, require weaker doses. By giving smaller doses, 5 to 8 grains at 12 A.M. and 4 P.M. daily, and continuing these until the temperature appears settled, the effect is to induce a steadier and more persistent attack on the thermal phenomenon. The object of the 12 and 4 o'clock administration is to intercept the evening rise.

In the accompanying chart the effect of cryogenine is The patient was a girl, aged 16 years, by occupashown. tion a clerk. She came under observation with acute pulmonary disease of short duration, Stadium ii. (Turban's classification), L. (infiltration both lobes). There was no expectoration, but a Calmette instillation was positive. The disease was of a particularly virulent character: the fever was high, there were profuse night sweats, and wasting was marked. From the period, Feb. 27th to March 28th, the patient was prescribed rest, good airing, special diet, which included raw-meat feeding, and the occasional manifestation of aspirin (5 grains, later 10 grains. three times a day). The rest, I may say, was not absolute: the patient was allowed to read, sew, feed herself, and go to the lavatory. The aspirin produced a transitory effect. On March 29th cryogenine (5 grains twice a day) was commenced, with no result. An increase to 7 grains twice a day produced in the course of a few days a fall in the temperature to normal. On April 18th the drug was discontinued, chiefly on the probability of immunity resulting if it were continued longer. The consequence was a decided elevation of the evening temperature, but at no point did the rise reach the former summits. The drug was re-administered on May 15th in 7-grain doses and immediately caused a normal reading. On the 27th the cryogenine was discontinued, and a few days later a last thermic flutter to 101° F. was exhibited, which was promptly discouraged by a renewed course of the drug. The patient was now gaining weight; the physical signs were satisfactorily clearing up. She was put on the usual course of graduated exercise and later graduated work. She was discharged very much improved, with slight physical signs, a gain of 29 pounds, and in a fit condition to return to her ordinary occupation.

The above case is one out of a number of successful results obtained from the use of this remedy. Contrasted with

pyramidon, which certain writers regard as the best drug for phthisical temperature, I think there can be little doubt that cryogenine is the safer and more efficacious antipyretic. Pyramidon shows a quicker and more pronounced fall—three, four, or more degrees, whereas cryogenine is content with a drop of two or more degrees. The former action is decidedly risky, as collapse may follow this sudden depression, especially if the fall be to subnormal.

Didworthy, South Brent, Devon.

A CASE OF PERIPHERAL NEURITIS (ALCOHOLIC).

BY JOHN WYLLIE, M.D. GLASG.

On Nov. 27th, 1908, I was asked to see a married woman, 40 years of age, to certify for asylum detention, but her mental condition did not seem to me to warrant such a grave step, an opinion with which Dr. Edward O. Daly of this city The woman admitted having taken drink freely Her tongue during the last 15 years—beer for the most part. was dirty, but not tremulous; breath markedly offensive; urine scanty and high-coloured, but contained no albumin or sugar, and had a specific gravity of 1020. She was ruddyfaced and still having her periods, which usually lasted a week. The liver projected two finger-breadths below the edge of the last rib and was hard; the spleen was larger than normal. The pulse was quick and at times irregular. and the apex beat was diffused; otherwise the heart and lungs were normal, as also was the temperature. The patellar-tendon reflexes were absent, and the patient had complained during the last few days of shooting pains in her legs, and she had been inclined to fall suddenly, her legs giving way without warning.

On Dec. 3rd she could no longer stand and could barely move her limbs in bed. The muscles in both upper and lower extremities were flabby and ill-nourished, and were the site of occasional spasm; both knee- and wrist-jerks were absent on the right and faintly flexor on the left side. She complained of her legs feeling numb, but not of tingling. There was some loss of appreciation of tactile stimulus and only a very slight response to faradic electricity. Muscular pians were very prominent, and she called out when a limb was grasped; the knee- and ankle-joints were very painful on movement, but there was no effusion. The patient had a thick, coarse voice, and when she worked herself into a state of excitement upon domestic affairs her breathing was apt to become laborious. Citrate of potash with nitrous ether and cinchona were given internally, and daily intramuscular injections of liquor strychniæ (10 minims) were begun. On Dec. 29th, as the neuritic and deep muscular pains were now much less marked, massage and the daily application of voltaic electricity were started. There was morning vomiting. The paralytic state was now more absolute than the note of Dec. 3rd conveys. The patient could not raise herself in bed or even raise her head from the pillow, or convey a piece of bread to her mouth; she could not raise her legs ever so little from the bed, or separate them more than a couple of inches, or turn over in bed. There was no paralysis of any cranial nerve, but beyond the power of laughing and crying, &c., the only voluntary powers present were the ability to swallow, to turn the head a little to either side and slightly to raise the forearms, and a restricted power over the bowels and bladder. There was a frequent desire to micturate and defæcate, which may be partly explained by highly concentrated urine in the one case and the presence of hæmorrhoids in the other, and if she was not provided with the bedpan quickly accidents happened, but there were no shooting girdle pains or bedsores. The pupils responded actively to light and accommodation, and colour vision was normal. The abdominal reflexes were normal and the other reflexes were in the same state as formerly noted, except that the slightly flexor state of the left plantar had dis-The muscles of the forearms were much wasted. as were the thenar and hypothenar eminences and the interossei; the muscles of the legs were not so much shrunken as those of the forearms, but they were very flabby. Tactile and thermal sensibility was now good, but all over the legs a pin-prick was spoken of as something cold, and the grasp

When the forearms of each hand was just appreciable. were raised the hands hung helplessly, exactly as seen in text-book illustrations of people suffering from lead-palsy. The lower limbs could only be drawn up an inch or two and the feet were in a straight line with the legs; the condition known as dropped foot, the effect of gravitation and paralysis of the anterior tibial muscles, being well shown. Joint pains were still very severe when the limbs were moved. The patient wandered a good deal at night and was said to have delusions, but I always found her coherent and rational. The reaction of degeneration of muscles was marked. Faradic electricity elicited feeble responses in both thighs, except on the outer side of the left thigh, where it was more active, but there was no response below the knees. Faradism was feeble in the forearms and normal in the arms. Voltaism of 8-cell power produced feeble responses in the extensors of the forearms and strong responses in the flexors. Both forms of electricity produced little irritability when applied to the nerve trunks of the arms (median and ulnar) and legs (peroneal and tibial).

On Jan. 10th, as the urine was less concentrated, the medicine had been changed to potassium iodide, capsicum, and strychnine, except when the neuritic pains were much in evidence, when a chlorodyne mixture was given. There were occasional attacks of orthopnœa. On the 16th the patient was much worse. During the night there were two severe attacks of difficult breathing, made worse from the fact that the sufferer could do nothing to raise herself into the sitting posture. She was ordered potassium iodide, digitalis, and nitroglycerine, and extractum stramonii (½ grain), to be taken at bedtime. Massage, electricity, and strychnine injections were to cease for a time. On Feb. 2nd the dropped hands were not so noticeable, slight wrist-jerks could be obtained on both sides, and the patient could lift a full soda-water syphon with her right hand and a half full one with the left, and she recognised pin-pricks over the whole of the four extremities. The power in the legs had been increasing during the last three weeks until she could now flex the legs well upon the thigh, but she required the assistance of an attendant in re-extending them. The feet could be raised a foot or more from the bed but were allowed to fall sharply. Ankle clonus had disappeared. On the 15th the patient could take her food in the sitting posture, with a chair behind her, and could feed herself, but in a jerky manner. On the 22nd she was always lying upon her right side and kept the left leg continually flexed, crying out when it was straightened, and in order to avoid the possibility of this faulty condition becoming permanent side splints were ordered to be applied daily for eight hours. On March 10th she could raise herself to the sitting posture by the merest touch of the attendant's hand, her legs were no longer kept in the flexed position, and she could change them from the flexed to the straight position without pain. Although the grasp of the hand was greatly improved she could not by her utmost efforts move the indicator of the dynamometer. On the 24th there was full control over the bowels and bladder, and the attacks of orthopnœa had ceased. As the dropped foot on both sides was becoming rigid, simulating equino-varus, the heel being raised and the sole turned inwards, and the hands were assuming a claw-like state, splints to counteract these conditions had to be applied. On account of the tendency to spasticity the hypodermic injections of strychnia were discontinued altogether. On April 1st tonic medicine was given instead of the iodide of potassium, tinctura ferri being preferred to quinine for a time on account of the patient being somewhat anæmic. On the 16th, with strong support on either side, the patient could stand, and she felt her weight upon her heels for the first time during her illness. On May 1st nothing had been said lately about delusions, the removal of hard plugs of wax. which pressed upon the membrana tympani on either side, possibly removing a source of reflex irritation.1 The reaction of degeneration had almost disappeared. matter of reflexes the condition was as follows :- Wrist-jerks : right, fairly active; left, just appreciable. Knee-jerks: right, active; left, appreciable. Plantar reflex: right, slightly flexor; left, absent. There was as yet no voluntary flexion at the ankle-joint, and if there was any at the toes it was very slight. The patient could feed herself fairly well, and with strong support could walk about 12 steps, but in a

¹ Three or four months after the close of the writer's attendance the patient was certified as insane.

thoroughly ataxic way. The hands and feet were quite supple, and could be moved passively in any way without pain.

Remarks.—The treatment was directed not only so to improve the state of the peripheral nerves as to restore feeling to the skin, which was more or less insensitive, and power to muscles which were paralysed, but also to create in the patient a distaste for drink. What was the cause of the orthopnœa? There was no bronchitis, lung trouble, or albuminuria, and the heart and valves were normal. suggest fatty degeneration or infiltration of the heart on the one hand and a faulty innervation of the organ on the other. Recovery is strongly against the former view and in favour of the latter, especially as improvement was coincident with the return of motor power in the limbs, and I think neuritis of the cardiac branch of the vagus is the correct answer. The inability to turn to one or other side or to rise from the recumbent position indicates that the neuritis was not confined to the extremities.

Vaso-motor disturbance was never very obtrusive; the legs and feet looked cold and livid and felt cold to the patient, and there was slight cedema of the dorsum of the left foot. The highly abnormal state of the lower reflexes, particularly the presence of ankle clonus, probably signifies that there was some change in the motor cells of the anterior cornua of the cord. Space forbids me to discuss the differential diagnosis, but I may say that the bilateral wristdrop and foot-drop, the deep tenderness of muscles, and the alcoholic history chiefly influenced me in concluding that my patient suffered from peripheral neuritis. Hull.

A CASE OF PNEUMONIA MIGRANS. BY H. BUCKLEY RODERICK, M.A., M.D. CAMB.

IN THE LANCET of Nov. 13th last, p. 1409, Sir Clifford Allbutt refers to a case of "pneumonia migrans" which he saw in consultation with me during its earlier stages. The progress of the case, ending in complete recovery, presents several points of interest, the details of which are as follows :-

The patient, a young lady, 27 years old, single, consulted me on July 13th last, complaining of slight occipital headache and feeling "out of sorts." Previously she had had no serious illness. In the autumn of 1908 she consulted me about a cough, some loss of flesh and appetite. As to the family history, her mother died from phthisis about the age of 40; one brother, now aged 21 years, is the subject of dormant caries of the spine; an elder brother is said to have recovered from pernicious anæmia; the rest of the family are apparently strong and healthy. At this time I carefully examined the patient's chest for possible early signs of tubercle, but could find none. I also subjected her expectoration, which was very slight, to bacteriological examination, with a like negative She rapidly recovered her usual health under a course of cod-liver oil and tonics, and I did not see her again until she consulted me on the present occasion.

The patient informed me that on July 9th she went for a cycle ride feeling perfectly well. She was caught in a shower of rain, but, in spite of her damp condition, rode on to a cemetery, where she remained some time arranging flowers on a grave. On the 10th she began to feel ill, and the following day being a Sunday, she stayed in bed, feeling cold and shivery. On Monday, the 12th, she kept about, but on Tuesday, owing to increasing headache, she came to consult me in the evening. Her temperature being 103° F. I told her to go to bed, and prescribed 10 grains of aspirin every four hours. During the night she was delirious at times and had no real sleep, the headache becoming more severe. The temperature ranged between 102° and 103°. respirations 24, and pulse 100. I examined her chest but could find no adventitious sounds. On the morning of the 16th, after another delirious and restless night, her temperature stood at 104°, and on examining her chest I found a small patch of consolidation hetween the right scapula and the spine. During the next two days the temperature ranged between 102.5° and 104°, but the most distressing symptom was a noisy delirium and sleeplessness, notwithstanding the administration of 15 grains of bromide every four hours

during the day and 7½ grains of veronal at 9 P.M. prescribed by Dr. Laurence Humphry, who saw her in consultation with me at this stage. On the morning of the 18th her temperature had dropped to 101.20, and, it being about the seventh day of the disease, I hoped that the crisis had been reached, but during the day it rose to 103.4°, and after another restless and noisy night the temperature at 2 o'clock the next day had risen again to 104.4°, and a patch of consolidation had appeared in a corresponding situation in the left lung. Another bad night followed, but her temperature came down by stages during the day and night following so that at 6 o'clock on the morning of the 21st the thermometer registered 99.4°

During this period the patient lay in a semi-comatose condition, with somewhat contracted pupils, muttering delirium, and occasional muscular twitchings. The urine on examination was normal; the sputum, scanty and never rusty, on bacteriological examination was found to contain some pneumococci, but no tubercle bacilli. On the advice of Sir Clifford Allbutt, who considered the case presented symptoms of meningitis, I performed a lumbar puncture which proved negative. During the 21st the temperature rapidly rose to nearly 103°, accompanied by a return of the delirium, and on the evening of the 22nd scattered patches of consolidation appeared on both sides of the chest. On the night of the 23rd the patient became noisy and very violent, and was not alleviated by a four-hourly dose of 15 grains of bromide and one hypodermic injection of morphia (4 grain). She refused all nourishment; her temperature oscillated between 101° and 103.8°. On the 25th Sir Clifford Allbutt again saw her in consultation and advised a half-drachm dose of chloral and 20 grains of bromide at 9 P.M. About 2 A.M. she began to perspire profusely, and slept for seven hours, her temperature rapidly falling from 103.8° to 101.5°. On the night of the 27th the restlessness returned, and on the following morning, her temperature standing at 102.5°, an urticarial rash appeared over the chest and abdomen. She was foaming at the mouth, the face distorted, the limbs twitching. At 2 P.M. the thermometer registered 103.8° and a fresh patch of consolidation appeared at the right apex. Tache cérébrale was very well marked. I here prescribed quinine sulphate (2 grains) every four hours. The twitchings continued throughout the night, but the temperature dropped to 100° by 10 o'clock the next morning, only reaching 101.8° during the day. She was here seen by Dr. Latham, who considered the case presented all the appearances of acute tuberculosis and advised the continuance of the quinine. At 5 A.M. on the 30th the twitchings ceased and the temperature remained at 100° till after mid-day, when it rapidly rose to 103 · 4°. The patient was quiet, showed signs of exhaustion, and continued in a semi-comatose condition. Throughout the 31st the temperature remained almost constant at 1020; at 6 o'clock on August 1st it rose suddenly to 104° and another patch of consolidation appeared on the left lung The right apex, under the third and fourth ribs in front. however, was distinctly clearing. From this, together with the fact that the very scanty sputum only contained a few pneumococci, I concluded that the infection must be pneumococcic and not tuberculous. Consequently on the 2nd, the temperature at 2 A.M. having been 104.20 and dropping at 2 P.M. to 102°, I injected ½ cubic centimetre antipneumococcic vaccine (Lister Institute polyvalent) containing 2,500,000 dead pneumococci. This was followed by a further drop in the temperature to 100° at 6 P.M. and to 98° at 6 the next morning. The patient, though exhausted, became quite conscious and rational. On examining the chest the right apex was found to be clear, but a dry pleuritic rub could be heard over the third left rib area in front. The temperature during the day only rose to 100.80 and descended again the next morning to 980. The right lung was quite clear and in the left lung could be heard sharp râles and coarse rhonchi. Next morning the temperature was again subnormal and did not exceed 100° during the day; the left lung was clearing fast. On August 5th the temperature remained practically normal all day and continued so, the patient making a slow, but uninterrupted

The striking features of the case were: (1) the cerebral symptoms, which persisted throughout the illness, varying from a semi-comatose state to a violent delirium; (2) the migratory nature of the pneumonia and the small area of

lung involved in each attack; (3) the slight disturbance of respiration, which only once reached 40 to the minute, being usually about 28; and (4) the rapid recovery after the small dose of antipneumococcic vaccine, which it is reasonable to suppose was instrumental in bringing about the favourable result.

Cambridge.

A CASE OF SYPHILIS OF THE PANCREAS WITH A PANCREATIC CALCULUS IN THE DUCT.

BY J. GEORGE TAYLOR, M.A., M.D. CANTAB., M.R.C.P. LOND.,

HONORARY PHYSICIAN, GENERAL INFIRMARY, CHESTER,

THE following case seems to me to be of sufficient interest

and rarity to be worth recording.

The patient, a man, aged 45 years, was admitted into the General Infirmary, Chester, under my care on Jan. 20th, 1909. His history was that he had been suffering from Bright's disease for 12 months and that six weeks ago he had had a fit. The family history was un-important except that his wife had had three mis-carriages, varying from the fifth to the seventh months of pregnancy, and that the feetus in each case was dead. On admission the patient was very weak; the pulse was hardly palpable, the expression was anxious, and the tongue was dry and brown. The temperature was 97.8° F., the respirations 28, and the pulse 94. The heart's apex beat was a quarter of an inch outside the nipple line, but no murmurs were heard. The lungs appeared healthy. In the abdomen a tumour was felt at the tip of the ninth right rib, protruding downwards and inwards towards the umbilicus for about 2 to 2½ inches. It was rounded in outline, something like half an orange, hard, and not tender on pressure, nor moveable. The dulness was continuous with the liver dulness, and the tumour appeared to be an outgrowth from the liver. There was some tenderness over the loins. The urine was of specific gravity 1012; it was acid, there was a large amount of albumin, but no sugar. No casts could be found. There was a good deal of ædema of the legs

In view of the family history it was thought that probably the abdominal tumour was gummatous in nature and that the albumin in the urine might be due to some lardaceous change in the kidneys secondary to syphilis. The patient was therefore ordered 20 grains of potassium iodide with drachm doses of liquor hydrargyri perchloridi three times a day. On Jan. 25th a pericardial friction sound was heard near the apex and also some pleural friction at the left base. On the 30th the albumin was distinctly less and the liver dulness was slightly diminished. For the last few days he had been feeling better. On Feb. 4th he vomited occasionally and the albuminuma was still getting less in amount. On the 9th he seemed less well; his pulse became very feeble and only 42 per minute. From then until the 13th he gradually got weaker and died during the evening of

At the post-mortem examination extensive pericardial adhesions were found; at the apex there was some hæmorrhage under the visceral layer of the pericardium. The left ventricle of the heart was hypertrophied. The aortic valves were healthy; the mitral, tricuspid, and pulmonary valves were sclerosed. The coronary arteries were hard and thickened. The aorta was atheromatous. The lungs were bound down practically all over by pleural adhesions and were very emphysematous. On section they showed much brown pigmentation. The liver weighed 48 ounces. and lower surfaces showed scarring and slight puckering, with bands of fibrous tissue running into the liver from the scars. The spleen was normal except for slight capsulitis. The suprarenals were normal. The kidneys were very granular, weighing 3 ounces each. The stomach and intestines were normal. The pancreas weighed 4 ounces; it was enlarged, being 6½ inches long and 2½ inches deep. It was very hard and very tough to the touch, feeling almost like leather. On making a longitudinal section and turning the front surface upwards two breaking down gummata were found; the larger was seven-eighths of an inch long and three-eighths of an inch broad. A very small calculus was iii., 172.

found in the main duct. It was about one-third of an inch in diameter, with a very irregular surface, brownish-white in colour.

Microscopically the pancreas showed marked fibrosis; in many places normal pancreatic tissue had quite disappeared. The smaller arteries showed well-marked changes in their walls, in some cases the endarteritis leading to complete obliteration of their cavity. There were also large areas of fat necrosis.

The calculus was very kindly analysed for me by Mr. W. Ffoulkes Lowe, A.R.S.M., F.I.C., and he reports as

Carbonate of		 	Trace Soluble			
Silica		•••	 	68 5 ·	١	
Alumina			 	18.0	l	
Ferric oxide			 	Trace	Insoluble.	
Silica Alumina Ferric oxide Magnesia	•••		 	Trace	,	
				100:0		

"There was no trace of phosphate in either the soluble or insoluble portion, and no oxalate or sulphate. The sand appeared to form a nucleus for the carbonate of lime, and the grains appeared to be coated over with the carbonate."

The case is interesting because syphilis of the pancreas is rare, and more so in the acquired than in the congenital form of the disease. When in acquired syphilis the pancreas is affected the result is usually chronic pancreatitis, whereas in the congenital form gummata generally occur In this case there were both chronic pancreatitis and gummata present.

Pancreatic calculi again are of great rarity. Dr. G. Newton Pitt 1 says that less than 100 cases are on record, and that in 11,000 necropsies at Guy's Hospital there were three cases only. They generally consist of carbonate and phosphate of lime, and carbonate of magnesia; in this case, however, the composition was extraordinary. There was no trace of phosphate and only a comparatively small ame unt of carbonate of lime, while silica and alumina composed practically the whole of the rest of the stone. The occurrence of silica in the human body is very uncommon. Thomson and Ferguson 2 report a case of intestinal sate in which the amount of silica present was 1 per cent. The only explanation I can give of the presence of silica in my case is that it may have been swallowed, for the man lived on the estuary of the Dee, and it is quite possible that in windy weather he might swallow sand in fair quantity, but why it should pass into the pancreatic duct I cannot see. Unfortunately the urine was not tested for Cammidge's reaction, as no suspicion of pancreatic disease arose during the time the man was in hospital.

Chester.

A CASE OF "STATUS LYMPHATICUS" WITH SUDDEN DEATH.

BY R. W. S. WALKER, M.B. CANTAB., M.R C.S. ENG., LATE HOUSE SURGEON AT THE GREAT NORTHERN CENTRAL HOSPITAL

THE condition described by Paltauf 3 as a clinical entity. and termed by him the "status lymphaticus," has been brought forward prominently of late in view of the frequent occurrence of sudden death during anæsthesia in persons suffering from this disease. I believe that these notes may be of interest from the mode of termination of the case. which was referable to no special exciting cause.

The patient, a male baby, came under observation at the age of 5 months, being brought to hospital for circumcision. He was small for his age and was well nourished, but was flabby and somewhat unhealthy in appearance; so, though no signs of organic disease were detected, I gave orders that he should be brought back in two months' time, since that was no urgency in regard to operation. Two months afterwards, while on my holidays, the child was brought back The mother was told to bring him again in a week's time

¹ G. Newton Pitt: Article "Diseases of the Pancreas" in Allbutt and Rolleston's System of Medicine, vol. iv., part 1, 1908, p. 314, 2 Thomson and Ferguson: Journal of Pathology and Bacteriology vol. vi. p. 334, 2 Paltauf: Wiener Klinische Wochenschrift, 1889, ii., 877, and 182, 179

when I should have returned. Four days after, while I was on duty, the child was brought in dead, and since I was unable to grant a certificate an inquest was held.

At the inquest the mother stated that the subject was the younger of twins and had been delicate since birth. He had been difficult to rear, and in comparison with the elder child had given rise to a great deal of trouble. He had never had definite symptoms of any disease, but had not grown well and was fretful and irritable. She had noticed nothing in particular wrong with him until the day of his death, when, while lying in the cradle, he suddenly became blue in the face and appeared to have a "convulsive fit." She wrapped a shawl round him and brought him straight to the hospital. She stated that she felt him move on leaving the house, but noticed no movements after this.

The post-mortem results were as follows:-The body was small for a child of 7 months, but was well nourished and presented no signs of wasting. The length was 26 inches, the weight 11 pounds. The changes found after death fell into two groups-changes associated with lymphatic enlargement, and changes connected with venous derangement. In regard to the former the thymus was hypertrophied, and instead of a weight of 11 drachms, weighed 2 ounce. There were no signs of any undue pressure on the trachea by this gland. The adenoids were enlarged, the tonsils small. There was considerable hyperplasia of the mesenteric glands, which were so pronounced as to resemble bunches of grapes. The Peyer's patches in the small intestine were markedly hypertrophied. There was but slight enlargement of the bronchial glands and of the Malpighian corpuscles of the spleen. No hyperplasia of the superficial lymphatic glands was present, and the thyroid was normal in size. was considerable engorgement of the great veins of the brain and of the neck and abdomen. The heart was normal in every respect save that there was considerable hypertrophy of the right ventricle; the pulmonary artery was not stenosed, the pulmonary valves were normal, neither was there anything suggestive of abnormality nor disease in the lungs. On section there was considerable change in the liver, which showed well-marked signs of chronic venous congestion. This was confirmed on microscopic examination. The body in every other respect was healthy and there were no signs of rickets. Microscopic section of the thymus and of a mesenteric gland showed marked hypertrophy of the lymphoid elements.

The lymphatism, with the exception of the lack of hypertrophy of the spleen, follows, I believe, the accounts of the post-mortem findings in the status lymphaticus with some detail, and the interest of the case lies in the mode of death which can be attributed to no special exciting cause, since the child was apparently lying quietly in the cradle. No signs of mechanical pressure on the trachea were found after death.

Leicester.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

JOINT MEETING OF THE MEDICAL AND SURGICAL SECTIONS.

ON Dec. 14th a joint debate was held under the presidency of Mr. G. H. MAKINS, C.B., on "The Diagnosis and Treatment of Duodenal Ulcer." The debate was opened by Mr. B. G. A. MOYNIHAN, followed by Mr. H. COLLINSON, and Sir T. LAUDER BRUNTON, Bart., Dr. W. HALE WHITE, Mr. F. S. EVE, and Mr. HERBERT WATERHOUSE took part in the discussion, which was adjourned on the motion of the last speaker. We shall publish an account of this important debate after it has been concluded.

CLINICAL SECTION.

Gumma simulating Malignant Discase. - Exhibition of Cases. A MEETING of this section was held on Dec. 10th, Mr. A. PEARCE GOULD being in the chair.

Mr. H. J. PATERSON read a short communication on a case of Gumma of the Breast simulating Malignant Disease. He said that a woman, aged 26 years, was admitted into the London Temperance Hospital under his care in November, 1901, suffering from a swelling in the right the casts. - Dr. POUNTON referred to some cases published in

breast. The patient stated that she had noticed a swelling in the right breast for three months. She had suffered little or no pain, but had lost flesh considerably. She was thin and extremely anæmic and looked very ill. Occupying the whole of the upper and outer quadrant of the right breast was a hard, somewhat irregular swelling, not adherent to the skin or deep fascia, but apparently sending processes into the surrounding breast tissue. No glands were felt in the axilla. He thought that the swelling was a rapidly growing sarcoma. Under chloroform he incised the swelling. It was densely hard and macroscopically and from its feel on cutting appeared to be a carcinoma, but a piece was frozen and examined microscopically in the theatre and reported to be a sarcoma. Accordingly, he sutured the exploratory incision and performed a Halsted's operation. The patient's general condition did not improve after operation and she remained extremely anæmic. Two weeks later the suture holes became ulcerated and small red nodules appeared in the surrounding skin. Gradually the skin bordering on the line of incision became brawny and indurated, and then ulcerated. After she left the hospital the ulcerated area slowly spread, and the axillary and supra-clavicular glands became enlarged. 14 weeks after the operation he noticed a smooth, hard swelling on the sixth rib in the axillary line. Thinking that this was probably a gummatous periostitis he put the patient on mercury and iodide of potassium. The swelling on the rib quickly disappeared, and in a few weeks the ulcerated area had completely healed. Fresh sections of the breast swelling were cut, and examination of them proved that the swelling was inflammatory, probably a gumma. He saw the patient about three years after the operation, and she was then in excellent health. After that he lost sight of her, and had been unable to trace her. The case was of interest not only on account of the difficulty in diagnosis, but on account of the rarity of gummatous disease of the breast. The rapidity of growth, the absence of enlarged glands, the age and general condition of the patient, led him to think that the case was one of sarcoma, a view supported by the microscopical examination of a piece of the swelling made at the time of the operation, although from the naked-eye appearance and character of the incised swelling he thought that it was a carcinoma. The patient did so badly after the operation that he feared she had secondary visceral deposits and that the operation would not benefit her much. The occurrence of periostitis of a rib gave a clue to the real nature of the case, and appropriate treatment speedily brought about a cure. As is so often the case, there was no history or other evidence of previous syphilitic disease.

Dr. McMullen showed a female patient, aged 62 years, suffering from Adiposis Dolorosa. There was a history of harmatemesis. The condition was first noted five years ago, and was then localised to one arm and circumscribed, but it spread rather rapidly. The changes were preceded by, and associated with, pain along the nerve trunks and hyperæsthetic skin areas. At present the upper segments of both arms, the back, and the sternal region were involved. Thyroid extract had been administered with a moderate degree of improvement.-Dr. A. M. Gossage described a case in which the patient seemed to be about the average from a mental point of view. Mr. V. WARREN Low emphasised the point that pain might precede the changes in the condition.—Dr. Leonard Williams pointed out that the disease occurred in women after the menopause.—Dr. F. J. POYNTON discussed the treatment of these cases by thyroid. and Sir DYCE DUCK-WORTH said that there was no doubt that the condition was affected by thyroid treatment and advised that the medicament should be taken at night. - Dr. J. GALLOWAY commented on a type of the disease in which there was unusual vaso-motor disturbance.—Dr. PARKES WEBER spoke on the nomenclature and incidence of the disease, and Dr. MCMULLEN replied.

Dr. W. P. HERRINGHAM demonstrated a case of Rheumatoid Arthritis with Albuminuria and with great enlargement of the liver. The patient was a boy, aged 15 years, who had been in hospital several times since November, 1905. In 1907 the liver was not enlarged. When admitted last June he was found to have the liver greatly enlarged, reaching as low as the right iliac crest; it was smooth, hard, and painless. No amyloid reaction with iodine had been seen in

THE LANCET in which definite lardaceous changes had been found.-Dr. PARKES WEBER said that in nine out of ten cases the enlargement was fatty.—Sir DYCE DUCKWORTH advised full doses of iodide of potassium for the patient, and Dr. H. D. ROLLESTON said that there was a toxemia in Still's disease which gave rise to nephritis, and that lardaceous disease was known to be due to toxemia of various kinds, especially the suppuration of syphilis; therefore, in exceptional cases toxemia in Still's disease might give rise to a lardaceous condition of the kidney and liver instead of nephritis.

The following cases were shown :—

Dr. J. R. Lunn: A case of Acromegaly.

Dr. R. MILNE: A case of Acromegalic Gigantism, and two cases of Achondroplasia.

Mr. A. CARLESS: Impaction of Large Calculus in the Lower End of the Right Ureter.

Mr. W. G. SPENCER: A case of Trephining for General Epilepsy.

Dr. F. J. POYNTON: Two cases of Congenital Œdema with Cardiac Defect in Mother and Daughter.

Dr. J. W. THOMSON WALKER: A case of Resection of the Bladder for Malignant Disease.

Mr. C. J. SYMONDS: Excavating Rodent Ulcer of the Face under Treatment by Radium.

Mr. A. SMITH and Mr. J. McDonagh: A case of Pachydermatocele.

Mr. F. S. Eve: Arterio-venous Aneurysm with Exophthalmos following an injury to the head; a case of Partial Luxation of Odontoid Process; and a case of Transverse Fracture of both Patellæ, with much separation of fragments, treated by_operation.

Dr. PARKES WEBER: A case of Recklinghausen's Disease and a patient a few months after omentopexy and peritoneal drainage for Chronic Ascites connected with Hepatic

Mr. C. A. BALLANCE: A patient on whom he had performed the operation of Trephining after Fracture of the Base of the Skull.

Mr. J. D. MALCOLM showed a patient who had undergone Cholecystduodenostomy for Acute Emaciation. The nutrition of the patient had steadily improved since the operation.

LARYNGOLOGICAL SECTION.

Exhibition of Cases and Specimens.

A MEETING of this section was held on Dec. 3rd, Dr. J. DUNDAS GRANT, the President, being in the chair.

The PRESIDENT showed the two following cases: 1. A case of Secondary Specific Pharyngitis in a woman aged 22 years, who, although quite healthy looking, had been sent to Brompton Hospital as presumably suffering from tuberculosis. On both faucial pillars there was symmetrical superficial ulceration, more marked on the left side, and of two months' There was neither history of syphilis, rash, nor post-cervical glandular swelling. Scrapings from the diseased surface revealed spirochæta pallida. 2. A man, aged 41 years, who was a considerable smoker, and showed a peculiar Erythema of the Soft Palate of three months' duration. A bright red rash was distributed over the soft palate, the hard palate having a white sclerotic appearance. In the discussion an opinion was expressed that the condition might be due to pyorrhœa alveolaris, which was also present. The patient had been in the habit of smoking 2 ounces of tobacco a week from a short pipe.

Mr. W. H. Kelson showed a case of Frontal Sinus Disease with Necrosis in a man aged 33 years. A year ago the patient was operated upon for suppuration in the left maxillary antrum, and immediately afterwards, owing to swelling in the frontal region, the anterior necrosed walls of the sinus and large sequestra were removed therefrom. Since then several small portions of dead bone have been removed.

Mr. H. BETHAM ROBINSON showed a man, aged 63 years, with a Flattish Ulcer creeping from the inner side of the left arytenoid cartilage on to the posterior part of the left cord, the posterior two-thirds of which showed some heapedup granulations, leaving the left side free. Mobility was normal. The right cord was healthy. The suggested diagnosis was senile tuberculosis.

belly) breathing on the stresses, strains, and frictions in the throat and larynx, more especially of the cricoid cartilage on the spinal column, and also the transverse axis of respiratory rotation of the cricoid on the thyroid cartilages. Dr. Spicer explained in detail how he arrived at the conclusion that the basic factor in causation of disease in the human body, and the production of disorders of the nose, throat, larynx, and voice, was the manner in which the respiratory function was nsed.

Mr. HERBERT TILLEY showed the two following cases: 1. Tuberculous Ulceration of the Epiglottis treated by amputation of the diseased portion. The patient was a man, aged 43 years, who, in March, 1907, had suffered slight pain on swallowing, loss of flesh, and profuse sweating at night. He also had physical signs of pulmonary tuberculosis with evening rise of temperature. The stump of the epiglottis was now quite healed and the patient had gained nearly three stones in weight since the operation. 2. The larynx of a man, aged 78 years, whose right vocal cord was removed for Epithelioma in September, 1896. From that time the patient enjoyed good health till a month ago, when he succumbed after tracheotomy performed (in other hands) for dyspnæa. A well-developed epitheliomatous ulcer now occupied the left cord, the original right cord and arytenoid remaining quite healthy.-In the discussion the generally expressed opinion was that this was a clear case of reinfection after recovery from the original disease.

Dr. STCLAIR THOMSON showed a case in which there had been Complete Stenosis of the Larynx after Diphtheria (for which tracheotomy was performed) in a boy when aged 1 year and 2 months, but complete recovery had now been obtained by intubations spread over three years. Dr. Thomson's object in showing the case was to illustrate (1) how laryngeal stenosis from diphtheria might occur, even although a satisfactory low tracheotomy had been carried out; and (2) the success of the latter in complete occlusion of the glottis when combined with intubation, the result being seldom equalled by laryngo-fissure and laryngo-tracheostomy.

Dr. G. WILLIAM HILL showed two cases treated by application of radium bromide. The first patient had suffered from a malignant tumour of the neck which manifested continued decrease of the swelling after the application of 50 milli-grammes for 22 hours. The second patient, who suffered from carcinoma of the gullet, had received six applications since July last, and could now swallow almost anything, instead of only purées and other liquids as formerly.

Other cases and specimens were shown by Mr. CHARTERS J. SYMONDS, Dr. GEORGE C. CATHCART, Mr. HAROLD S. BARWELL, Dr. W. S. SYME, Dr. JAMES DONELAN, and Mr. P. R. W. DE SANTI.

THERAPEUTICAL AND PHARMACOLOGICAL SECTION.

Phosphorus Poisoning.—The Lactic Acid Bacillus.

MEETING of this section was held on Dec. 7th. Professor A. R. Cushny, the President, being in the chair. Mr. H. WIPPEL GADD read a report upon Kangalugi Root.

Mr. R. G. HANN and Dr. R. A. VEALE contributed at account of a case of Phosphorus Poisoning, and showed pathological specimens obtained therefrom. The drug had been taken as an abortifacient, and besides the more usual fatty degeneration the viscera showed numerous larg-hæmorrhagic extravasations. In addition there were enormous subcutaneous hæmorrhages covering a large part of the superficial extent of the body.

Dr. GEORGE HERSCHELL opened a debate upon the Therapeutic Value of the Lactic Acid Bacillus. He emphasised the necessity of selecting suitable cases and of using an active preparation, and said that only two or three of the solid preparations on the market contained the Bulgarian bacillus The conditions suitable for treatment were those where there was abnormally great putrefaction of proteids in the alimentary canal, with auto-intoxication from the colon. No good results were to be expected where the symptoms were due to an excessive fermentation of carbohydrates. He had met with marked success in the treatment of the former cases.—Dr. F. W. GOODBODY said that he had searched for evidence on the chemical side of good results, but had met. to a great extent, with negative results. Aromatic sulphates were not appreciably diminished .- Dr. VAUGHAN HARLEN Dr. Scanes Spicer showed a model to illustrate the said that he agreed with the opinion of Dr. Goodbody variation in effect of costal (or back) and abdominal (or The evidence of changes in the composition of the

fæces was disappointing, considering the improvement which had occurred in the symptoms. He thought that these good effects were psychological in origin. His experience was that improvement occurred in functional dyspensias but not in those that were associated with organic change.—Dr. W. BULLOCH said that he had examined over 20 specimens of the tablets placed on the market and none had showed the presence of active bacilli. They might be each and all discarded as worthless.—Dr. J. W. H. EYRE said that working with his own strain of bacilli he had had success in treating certain infections of the colon with pathogenic bacteria. Successive cultivations from the fæces had shown rapid diminution of the pathogenic micro-organisms. - Dr. ROBERT HUTCHISON expressed himself as profoundly sceptical of the good results claimed, and this feeling was strengthened by what he had just heard. To diminish intestinal putrefaction he would rather trust to small doses of calomel. He hoped that the discussion would go far to suppress a dangerous craze.—Dr. C. H. MILLER said that he had used the method in a series of cases of rheumatoid arthritis. The arthritis benefited little, but the general health of the patients improved greatly.—Dr. A. F. HERTZ said that he was sceptical of the existence of auto-intoxication from the bowel. He related a case of streptococcal infection of the bowel which had resulted in rapid recovery when soured milk was Simultaneously the streptococci disappeared from the He thought that such bacterial control was necessary.—Dr. W. Langdon Brown said that he had certainly seen indicanuria disappear during treatment by this means.

SECTION OF AN ESTHETICS.

Lymphatusm.

A MEETING of this section was held on Dec. 3rd, Mr. RICHARD GILL, the President, being in the chair.

Mr. H. BELLAMY GARDNER and Dr. R. SALUSBURY TREVOR communicated a paper on Lymphatism, with specimens and lantern illustrations. The importance of the subject as bearing upon the explanation of sudden death in children and adults was pointed out. The normal weight of the thymus gland, according to Dr. L. S. Dudgeon's researches, was stated to be from 7 to 10 grammes. The fluid expressible from the gland post mortem was normally sterile and of an acid reaction. Dr. McCardie had stated that Paltauf in 1889 first pointed out that many cases of sudden death, otherwise unexplained, were found post mortem to have enlarged lymphatic glands, enlarged thymus and spleen, hypoplasia of the aorta, and swelling of solitary follicles of the intestine and of Peyer's patches. In infants and young children death was often preceded by fits of stridor, and ended in sudden asphyxia; in older children and adults respiration ceased without obvious dyspnœa, and the heart failed immediately. Enlarged thymus was often also found in association with rachitis, exophthalmic goitre, myasthenia gravis, and leukæmia. Photographs of frozen sections of the normal newborn infant were shown to demonstrate the position of the thymus gland in relation to the œsophagus, trachea, innominate artery and aorta at the levels of the sixth cervical, first, third, fourth, and fifth dorsal vertebræ respectively. Six cases of sudden death presenting enlarged thymus gland and general lymphatism were then related. 1. A boy, aged 13 months, died suddenly while a physician was at the bedside. There was no sign of asphyxia. Respiration and circulation stopped simultaneously. 2. An infant, aged 9 months, with recently healed eczema, died within an hour after onset from tracheal stridor, with asphyxial symptoms. 3. An adult, aged 29 years, a congenital imbecile, died suddenly in a tepid bath from respiratory and circulatory failure. 4. A female, aged 30 years, who died suddenly under a local ansesthetic (tropacocaine) for the removal of a small cyst in the neck. Respiratory cessation; no dyspnœa. Heart failed later. 5. A male, aged 14 years, died at the third inspiration of ethyl chloride given for the adenoid operation. There was no respiratory obstruction. Respiration failed first, and then the heart. 6. A male, aged 13 years, died during an operation for adenoids and tonsils under C1E2 mixture. There was no respiratory obstruction. Respiration ceased while the corneal reflex persisted. This negatived overdose of anæsthetic. The circulation failed rapidly. The thymus weighed 56 grammes. There were enlarged

lymphatic glands in the infra-tracheal group, mesentery, and inguinal regions, enlarged Peyer's patches and solitary follicles throughout the intestine. This was a grossly marked case, and was illustrated by 12 lantern-slides of the parts affected, explained and demonstrated by Dr. Salusbury Trevor. A history of chronic eczema, a severe attack of measles, and abscess in the middle-ear were afterwards disclosed. A chronic toxemia had been suggested as the cause of the general lymphatism by several writers. Gallois has suggested that this was a mild septi-cæmia due to swallowed muco-pus from the naso-pharynx. In the present state of knowledge these sudden deaths presented a problem worthy of most active research on the part of the medical profession. The means of diagnosis pointed out by A. S. Warthin might apply in well-marked cases—i.e., percussion of the thymic area over the manubrium sterni, yielding unusually wide dulness, radiographic examination for wide thymic shadow above the heart, palpable cervical, axillary, or inguinal glands. Mr. Bellamy Gardner particularly dwelt upon the importance of discovering (1) the cause of these sudden deaths; (2) in what subjects to suspect lymphatism; (3) how to diagnose it; (4) how to treat it; and (5) how to safely conduct anæsthesia in such subjects.

Dr. DUDLEY W. BUXTON said that the subject of the status lymphaticus in its relation to deaths under anæsthetics was complicated by the fact that great confusion existed in the clinical records of such cases. The physical signs were so confusing that one was led to believe that the conditions called lymphatism, thymic death, and thymic asthma were, in fact, variants from some common dyscrasia, the nature of which was at present unknown. Theorising was inevitable, and the theory that these conditions were but symptoms of different stages of some toxemia, probably a lymphotoxemia, appeared to the speaker to supply the best explanation of the central malady. The mechanical theory of death was certainly untenable, as cases in which definite pressure by the thymus like those in which thymic asthma existed presented such well-marked symptoms that any general anæsthetic would be withheld. The cases in which no symptoms existed, but which revealed lymphatic hyperplasia, varied in degree and no doubt were very common. Until they knew the incidence of such conditions in persons who survived anæsthetics they could not say whether they were indeed more likely to die during narcosis. He suggested that a subcommittee should be appointed to study the subject. What appeared to be clear from the record of the cases of death under anæsthetics was that the patients were suffering from a depressed vitality, the signs of which Dr. Buxton enumerated, and that their blood pressure was abnormally low,

exceptionally weak vapours and always supplying oxygen with them. Cases were on record in which the patient who eventually died under chloroform had survived it many times Probably in the one instance more, and in the others less, powerful vapours had been employed. thought that all persons who conceivably were of this dyscrasia should be dealt with on the lines indicated, whether they appeared robust or as in the exophthalmic goitre cases they gave evidence of definite disease which probably interfered with normal respiration. It was safer to assume a disease which might not be present than to overlook one which presented no clear objective signs.

due in part to the state of the heart muscle. Myocardial

disease was a constant accompaniment of, if not a part of,

lymphatism. It followed that these persons could not take the usual and safe strength of chloroform without grave

risk. Asphyxial complications, trivial in most cases, caused

serious results in them. Hence his insistence upon giving

Dr. LEONARD WILLIAMS believed that status lymphaticus was due in most cases to a want of work on the part of the thyroid gland, and that the other minor glands were enlarged to make up for the lack of efficiency of the thyroid.

Dr. B. H. SPILSBURY said that too much emphasis had been laid on the size of the thymus gland; a thorough microscopical examination of the structures was essential, the naked eye appearances not being sufficient evidence on which to form a diagnosis. The heart muscle was always degenerated to some extent in these cases, either fatty degeneration or brown atrophy, or a combination of the two being an essential feature of status lymphaticus. Dr. Spilsbury denied that the condition was necessarily congenital; in some cases he had

found distinct evidence that the thymus gland had atrophied in the ordinary way during childhood and grown again later in life. Of all the cases of death during anæsthesia in which he had made a post-mortem examination about 75 per cent. had shown signs of status lymphaticus, and this condition is, in his opinion, a more important factor in causing death than the anæsthetic employed.

Dr. F. W. Hewitt said that before putting deaths down to status lymphaticus, they ought to consider whether the individual cases could not be explained on other grounds. In many cases an asphyxial factor was present before the sudden death occurred; but this might be so slight as to pass unobserved. He did not think that the heart was really an important factor in causing death. If the respiration was kept absolutely free, and the amesthesia was not too profound, it was nearly always possible to avert an accident.

MEDICAL SOCIETY OF LONDON.

Anatomy of the Heart .- Auricular Fibrillation.

A MEETING of this society was held on Dec. 13th, Dr. SAMUEL WEST being in the chair.

A paper by Professor ARTHUR KEITH and Dr. IVY McKenzie, entitled "Recent Researches on the Anatomy of the Heart," was communicated; this will be published in full in a forthcoming issue of The Lancet.

Dr. Thomas Lewis delivered an address on Auricular

Fibrillation and its Relationship to Complete Irregularity of the Heart as it Occurs Clinically. He spoke of the two groups of cases with which complete irregularity is particularly associated—namely, advanced mitral stenosis and general degeneration of the cardio-vascular system. He gave the general clinical features, the type of sphygmographic tracing, the venous pulse curve, and laid particular stress on the absence of all signs of normal auricular contraction. He then referred to certain phenomena indicating activity of the auricle, more particularly hypertrophy of the auricle, found at necropsy, and the reappearance of signs of normal auricular contraction in paroxysmal cases of the affection at the time when the normal rhythm returns. He next turned to the electro-cardiographic evidence of the condition. The change from the normal type of curve to that of the type met with in complete irregularity was described. It was stated that in this condition the curve consists of two parts, one attributable to ventricular activity, and the remainder of the curve was constituted of irregular waves the result of auricular activity and replacing the normal auricular peak. These waves are known to result from auricular activity because they appear in their maximal form when leads taken directly from the chest wall lie directly above the right or superficial auricle. The pure ventricular curve can be similarly obtained by leads suitably placed in relation to the left ventricle. Dr. Lewis referred to two forms of auricular activity-coördinate and incoördinate. He noted the evidence for the absence of coordinate contraction, and concluded that incoördinate contraction was present as the result of the information afforded by these direct leads. Finally, a comparison was made between the records yielded by complete irregularity in man and auricular fibrillation in the dog. 1. Dealing first with the radial pulse, the following features in common were described : complete irregularity, increased rate, and an absence of relationship between the size of the beats and the pauses preceding them.

2. He dealt next with the venous curves, and showed that in both dog and man a ventricular form is present and small oscillations of pressure occurring in the veins are common to both when the pulse is slow. 3. He next compared the electric cardiograms from the two conditions. Slides were shown demonstrating how identical the curves were from dog and man, and the following special features which the curves presented in common were emphasised: the presence of the first ventricular variation R., showing the supra-ventricular origin of the beat in each case, its increase in size as compared with the normal condition, the absence of relationship of its height to preceding pauses and to sizes of corresponding arterial beats, and the presence of the curious waves replacing the normal auricular waves, waves which can be directly shown to proceed from the fibrillating auricle in the case of the dog.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

President's Address.—Hypertrophic Cirrhous of Liver with Alcoholic Paralysis.—Exhibition of Specimens.

A MEETING of this section was held on Nov. 12th, Mr. A. H. BENSON, the President, being in the chair.

The President delivered an address on the subject of Trachoma.

Dr. H. C. DRURY read notes of a case of Hypertrophic Cirrhosis with Alcoholic Paralysis, the patient being a large stout woman, aged 42 years. She had had 20 pregnancies, with 13 living children and 7 miscarriages, these latter having been irregularly distributed between the live births. There was no history or evidence of syphilis. She was admitted to hospital in a state of alcoholism, and she had an alcoholic history. She complained of weakness and "pins and needles" in her feet and hands. There was an abrasion on both knees from her legs having "given under her" on getting out of bed. Her mind was quite clear. The lungs were healthy. The heart was strong and regular, but there was a mitral systolic murmur. There was not, however, any evidence of failing compensation. The movements of the limbs were good. and the hands could be fully extended, but the muscular action was weak. The muscles of the arms, especially of the extensors, were painful to pressure; those of the legs were in a similar condition, and attempts at voluntary flexion caused pain in the calf. The reflexes were absent, while sensation, though perverted, was still present. It was evident that the patient was in an early stage of peripheral neuritis. This gradually developed from day to day until there resulted complete "drop wrist" and "drop foot." She could draw her legs up in bed, but could not extend them again. The abdomen was very large and pendulous; at the umbilious was a tumour of about the size of a hen's egg, which was the empty thickened sac of an old-standing umbilical hernia. The liver and spleen were both greatly enlarged; there was no ascites. Jaundice was present, the conjunctivæ being of a bright yellow colour, but the colouration of the skin was such that it might easily escape notice. The urine was high coloured and clear, without albumin or sugar; it gave the iodine reaction for bile. The fæces were lighter than normal in colour, but contained bile colouring matter. The liver was very large, reaching in the parasternal line more than two hand breadths below the lower border of the ribs. It was readily palpable, being smooth and firm, with a sharp hard margin, but of normal shape, and painless. Simple hypertrophy was excluded by the extreme firmness of the organ and the remarkable sharpness of the edge; it was, moreover, larger than was likely to be the case in simple fatty liver. Amyloid disease was excluded by the absence of any cause for such, the history of the pregnancies being alone sufficient to preclude syphilis. All the symptoms indicated hypertrophic or biliary cirrhosis. The patient had a continuous but quite irregular febrile temperature for some five days, and then (Oct. 10th developed a profuse diarrheea without assignable cause She became rapidly weak, fell into a heavy lethargic or sent comatose state, and died rather suddenly on Oct. 24th. The great enlargement of the liver having the characters already described, the enlarged spleen, the jaundice without ascitethe irregular pyrexia, the profuse diarrhœa, the bile-coloure fæces, and the great asthenia passing into semi-coma and death, together produce the clinical picture described if Hanot, which has been named hypertrophic, or biliary. insular cirrhosis of the liver.

Professor A. C. O'SULLIVAN gave the following account the post-mortem appearances: "The liver weighed? pout 11 ounces. The increase in size was fairly uniform in but 11 ounces. The increase in size was fairly uniform in the side to side. Its capsule was somewhat thickened; it we finely granular on the surface and of a light greenish-yellow. On section, the connective tissue was seen to divide liver up into small areas about as big as, or smaller that a lobule. Under the microscope there was a great quant of connective tissue arranged on the whole with a tender to surround lobules. It also sent delicate strands everywhere in between the liver cells. There was extensive facilities.

infiltration and the liver was stained green in places with bile pigment. The connective tissue outside the lobules contained great quantities of newly-formed bile ducts. A section of the external cutaneous nerve showed extensive degeneration, all the larger fibres being degenerated; the myelin and axis cylinders were broken up and the nuclei of the sheath were increased."

Dr. J. B. COLEMAN exhibited Viscera of a woman, aged 34 years, who died with symptoms of gangrene of the lungs, consecutive to perforated gastric ulcer, the sinuous track of which led, by a perforation in the diaphragm, into an abscess cavity between the diaphragm and the base of the left lung. The lower lobe of that lung contained several abscesses and gangrenous areas.

SECTION OF MEDICINE.

Spleno-medullary Leukamia. - Sane Hallucinations.

A MEETING of this section was held on Nov. 26th, Dr. WALTER G. SMITH, the President, being in the chair.

Mr. MAURICE R. J. HAYES read a paper on Spleno-dedulary Leukæmia Treated by X Rays. The case was that medullary Leukemia Treated by X Rays. The case was that of a woman, aged 42 years, married, no children. Symptoms directly referable to her disease began in August, 1906, but the enlargement of her spleen was first apparent in December, 1908. In February, 1909, when X ray treatment was commenced, she was very animic and wasted; she suffered much from breathlessness and palpitation, her legs were swollen and she had hæmic murmurs. Her spleen extended for two inches to the right of the middle line, for three inches below the umbilicus, and to the level of the crest of the left ilium. The liver was slightly enlarged; there were no enlarged lymph glands. For purposes of irradiation the superficial area of the spleen was divided into four circular areas, 10 centimetres in diameter, and each one was exposed in turn, a hard tube being used. The average duration of each exposure was 18½ minutes. From Feb. 20th to Nov. 25th, 1909, 22 exposures were given. She had no treatment during July, August, September, and October, when she felt very much improved and was able to perform her household duties. Her spleen had reduced in size till it was palpable for 2½ inches below the left costal arch, and it was freely moveable. Palpitation, breathlessness, and cedema had disappeared, and she looked very well; the anæmia was better. In the end of October her symptoms returned, and X ray treatment was resumed in November, to which she is responding. She has had no medicinal treatment whatever for her disease. She at no time in the course of treatment suffered from any general or local symptoms which might be referred to the X ray, save a slight dry dermatitis in April, when irradiation was suspended for three weeks. The reports on the blood-films, which were examined by Professor E. J. McWeeney and Dr. W. D. O'Kelly, are as follow:-

-The President, Dr. E. J. M. Watson, Professor McWeeney, Dr. W. G. HARVEY, and Dr. C. M. BENSON discussed the case. Dr. A. R. Parsons quoted a case of his own which was almost identical with Dr. Hayes's case. She was 55 years of age, and had had a prolonged course of arsenic without any improvement. The condition of her white cells was almost identical at the end of the treatment with what it had been at the beginning. After the tenth or twelfth application of the X rays a marked improvement took place in her blood, and the spleen decreased to such an extent that it was almost impossible to palpate it. She went away feeling perfectly well but returned within a year's time with the spleen increased and a relapse in the condition of the blood. She again received benefit from the rays but died in six months. It was quite certain that the rays effected a diminution of the spleen, but how it was brought about he did not know. The improvement in the blood was not brought about by the destruction of the white cells, although the rays might inhibit their formation.

Dr. R. J. ROWLETTE said he had performed a postmortem examination last year on the body of a patient who had died from heart disease while under X ray treatment. The leukamia was discovered when she was put to bed in hospital, and as far as it was concerned she had improved considerably. In the microscopic examination of the spleen he did not find any of the patches which were said to be typical of the disease, and it was possible that the X rays had caused their disappearance.

Mr. HAVES, in reply, said he believed the woman's present condition to be due altogether to the X ray treatment. Out of 63 cases collected as treated by the rays only four were alive in from three to six years after the primary symptoms, so that it did not promise very well for the patient.

Dr. W. R. Dawson read a patient's autograph account of Sane Hallucinations.

Medico-Legal Society.—A meeting of this society was held on Nov. 23rd, when Dr. J. E. Risien Russell read a paper on the Effects of Traumatism upon the Nervous System. Although he did not include the effects of gross lesions of the nervous system, he did not confine his remarks to the subject of traumatic neurasthenia, but rather attempted to show that although no evidence of structural damage of the nervous system might be determined immediately after an accident, subsequent changes might take place in the nervous system which could give rise to signs which are regarded as evidence of organic disease. The way in which these symptoms and physical signs developed after an accident made it difficult to escape from the belief that the altered condition of the nerve elements is the outcome of the accident. He emphasised the fact that the symptoms of traumatic neurasthenia might follow an accident of the most trivial kind, and considered that the conditions under which the accident is sustained have more to do with the result than the actual severity of the injury, provided no actual structural damage has been done to the nervous system. In short, the mental shock sustained is an important factor in the production of the symptoms. In his experience the age of the patient and the state of the blood-vessels are other important factors which often influence the prognosis unfavourably, but nothing is more difficult than to say how long a case of traumatic neurasthenia is likely to take to get well, even after trivial injuries. How far antecedent disease should be allowed to influence the question of compensation was next considered, as was the question of how far a plaintiff for damages would prejudice his case by refusing treatment. He supposed that there could be no doubt as to the result if it could be shown that the claimant deliberately aggravated his condition by some wilful neglect or similar act, but the refusing of treatment could not be viewed in the same way, for it was conceivable that the suggested treatment might not only be uncongenial to the patient but actually harmful to his condition. He advocated the Weir Mitchell or "rest-cure" treatment in these cases, and advised that, when possible, the treatment should be conducted in homes in the country devoted to the care of nerve cases, and was further of opinion that there is great advantage in placing such patients under the personal influence of a resident medical officer whose whole time could be given to the care and management of the patients. Admirable as was this treatment, it could not be said that a course of the kind for a certain number of weeks or even months would necessarily result in cure, for he had known many cases in which no question of compensation arose and in which, nevertheless, prolonged treatment on this and other approved lines failed to bring about improvement in the patient's condition. Dr. Russell next dwelt on the importance of being able to recognise the features of a malady that could not be reasonably ascribed to an accident and which may have existed before the injury and which, even if it had developed subsequently, must yet be regarded as independent of the trauma. Although organic changes could result from injuries to the nervous system, the clinical picture of a very few diseases could be thus established, so that the determination of certain diseases made it impossible to associate the injury with them as cause and effect. In conclusion, he advocated the extension of the system of consultations between the medical men who appeared on the opposite sides before the case came into court, and he hoped that it might be found

possible for the society to use its influence to promote what he considered was a much needed reform in regard to medical evidence in the courts of law. He spoke in complete ignorance as to what was possible in this way, but he could not help feeling that it would be a good plan if medical assessors could be appointed to assist the judge and jury in their deliberations in cases in which medical evidence was called. There could be no doubt that this reform would be of great advantage to the medical profession, and he believed that it would also be of advantage to the public, but he could not, of course, venture to express an opinion as to how the legal profession would view any such alteration of the present mode of procedure.

MANCHESTER MEDICAL SOCIETY.—A meeting of this society was held on Dec. 1st, Mr. W. Coates, the President, being in the chair.—Dr. E. S. Reynolds read a communication on the Importance of Rectal Examination in Medical Practice, referring only to those cases in which symptoms were not obviously due to rectal mischief but in which rectal examination was essential before a correct diagnosis could be made. He alluded specially to three groups of cases and related illustrative examples: (a) Profound and even fatal progressive anæmia due to slight but repeated rectal hæmorrhages; (b) malignant disease of the rectum or in the pelvis; and (o) pelvic abscess secondary to appendicitis.-Dr. J. Barnes Burt read a paper on the Etiology of Heberden's Nodes, which was an attempt to prove that Heberden's nodes are compensatory changes brought about by the constant use of the terminal phalangeal joints when the ligaments of those joints are weakened by disease or degeneration. The paper comprised:
(a) A description of the five different views relating to
the origin and clinical significance of Heberden's nodes. (b) An analysis of 40 consecutive cases showing the following points: (1) Heberden's nodes occasion a variety of conditions which are in no way connected with one another; (2) they are always preceded by some condition which leads to weakening of the joint ligaments; and (3) the more the joint is used the greater the liability to these nodes. Thus if the ligaments are weakened constant use of the terminal phalangeal joint leads to the last phalanx being tilted backwards because opposition to the thumb is the chief action of this phalanx. The posterior margins thus receive an extra degree of pressure and will therefore hypertrophy, the pressure being intermittent. The hypertrophy of the most prominent portions of the margins forms Heberden's nodes; in other words, Heberden's nodes are compensatory changes. Chronic gout, rheumatoid arthritis, senile degeneration, and wear and tear may all be important factors in the production of this disease; but just as hypertrophy of the heart is a compensatory change occurring in a variety of conditions so Heberben's nodes are a compensatory change and not a sign of one specific disease. - Dr. H. H. McNab read a paper on the Importance of Early Treatment in cases of Convergent Strabismus, pointing out the value of Claud Worth's researches and emphasising the necessity of curative measures being undertaken at the earliest possible date after the appearance of the squint.

United Services Medical Society.—A meeting of this society was held on Dec. 8th at the Royal Army Medical College, Grosvenor-road, S.W., Lieutenant-Colonel W. G. Macpherson, C.M.G., R.A.M.C., being in the chair.— Fleet-Surgeon F. H. A. Clayton, R.N., read a paper entitled "Notes on Seven-day Fever of Eastern Ports: its Occurrence in the Navy and its Relationship to Dengue." It was pointed out that so far as the navy is concerned Bombay was the principal source of cases of fever of this particular type. A brief sketch of the symptoms and of such facts bearing on causation as are at present known was given and the results of investigation into its occurrence in the East Indian Squadron for a period of ten years were then detailed. This showed that in the Naval Defence Flotilla permanently stationed at Bombay outbreaks seemed to occur at almost any time of year and were apparently chiefly dependent on the supply of susceptible individuals. In the smaller ships, on the other hand, which were docked for a considerable time, outbreaks always coincided with docking, and the possibility of its occurrence seemed to vary with the length of time in dock and the number of white men on board. The larger ships in Bombay harbour for considerable periods but only docking for a few days

were practically immune except in one instance. The analogy which existed therefore between the occurrence of this disease and that of malaria in ships was then discussed, and the conclusion arrived at that the facts suggested convection by blood-sucking flies. Various points which might appear to argue against this conclusion were dealt with, and the history of an outbreak in 1907 was given which offered some support to it. The question of the variety of fly likely to be responsible was discussed, and C. fatigans was, on the whole, held to be the most probable. The second part of the paper was devoted to a consideration of the Relationship of Seven-day Fever to Dengue. The history of the disease was briefly related and Megaw's papers were referred to. Instances were given of the occurrence at the termination of epidemics of cases having some of the characteristics of both diseases, and a history of an outbreak was then related in which what appeared to be originally seven-day fever assumed, following on the change of locality, many of the chief characteristics of epidemic dengue. In the concluding part of the paper reference was made to some of the possible factors which operate in the conversion of the sporadic to the epidemic form of dengue. The final conclusions come to were—that on the whole naval experience suggested the convection of seven-day fever by a biting insect, possibly C. fatigans; that the disease is in reality a sporadic form of dengue, its epidemic extension being promoted by certain unrecognised factors.—In the discussion which followed it was generally agreed that a good case had been made out for regarding seven-day fever as a sporadic form of dengue. Questions were asked as to the character of the pains, the occurrence of the rash, the prevalence of seven-day fever on the China station, whether observations on the Widal reaction bad been carried out in cases of the disease, and if immunity followed attack.— Among the speakers were Major W. S. Harrison, R.A.M.C., Lieutenant-Colonel Sir W. B. Leishman, R.A.M.C., Major S. L. Cummins, R.A.M.C., Fleet-Surgeon J. A. Keogh, R.N., Deputy Inspector-General S. T. O'Grady, R.N., Staff-Surgeon M. H. Knapp, R.N., Staff-Surgeon R. St. G. Bond, R.N., and the President.—Fleet-Surgeon Clayton replied and the proceedings terminated with a hearty vote of thanks

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL Society.—A meeting of this society was held on Nov. 26th, Dr. J. B. Hellier, the President, being in the chair.—Mr. Leonard A. Rowden read a paper, illustrated with lantera slides, on the X Ray Diagnosis of Renal Calculus. He dwelt on the importance of using a fluorescent screen and not a photographic plate for the purpose of diagnosis, pointing out that if the plate alone was relied on, many calculi might be overlooked. He also insisted on the area of illumination being cut down to its smallest possible limits so as to do away to a large extent with the general fogging of the picture produced by the secondary radiations. Out of a series of 400 examinations 92 cases were operated upon and the diagnosis was found to be correct in 95.4 per cent.-Dr. A. H. Bampton read a paper on the Medical Aspect of Complete Suppression of Urine, and narrated a case where there was complete suppression for ten days, with but slight symptoms up to the eighth day; there was neither clouding of the brain, nor acceleration of the breathing and pulse, nor gastro-intestinal disturbance; the temperature was also subnormal. The patient died unconscious, but without convulsions, on the eleventh day. At the post-mortem examina-tion the bladder was found empty and there was no mechanical obstruction in the urinary tract. The kidneys showed interstitial nephritis. Dr. Bampton said that similar cases had been reported by Sir Dyce Duckworth and Professor W. Osler, and he discussed various theories to account for the arrest of physiological functionnamely, (1) the stop-cock action of arterial supply, (2) the "choked-filter" theory, and (3) the retension of toxins which paralysed the renal epithelium.—Mr. B. G. A. Moynihan showed an Enlarged Prostate, weighing 241 ounces, removed in June last. The patient had suffered for nine months from symptoms of prostatic obstruction. A large tumour was palpable above the pubes. The prostate was removed by the suprapubic route. The wound was slow in healing, but was closed in seven weeks. -- Dr. A. Sharp showed two cases illustrating Tertiary Manifestations of Syphilis of the Larynx. One showed a diffuse infiltration involving the ventricular bands and inter-arytenoid regions and causing troublesome dyspnœa and loss of voice. The other case showed a typical tertiary ulcer—the remains of a disintegrating gumma—involving the true and false cords of the left side. It was pointed out that potassium iodide was much more efficient in circumscribed than in diffuse infiltrations, and that in the latter mercurial inunction with iodide gave the best results.—Mr. H. Collinson showed a Circular Tin Disc half an inch in diameter removed from the larynx of a child, aged 4 years. The child was admitted to a hospital late at night when skiagraphy was impossible. High tracheotomy was performed and the foreign body was found to be tightly impacted below the glottis.—Mr. Walter Thompson showed a Sloughing Testis following Influenza.—Dr. E. F. Trevelyan showed a case of Pachyderma Laryngis in early Pulmonary Tuberculosis.—Other cases and specimens were also shown by Mr. H. de C. Woodcock, Mr. H. Secker Walker, Dr. T. Churton, Dr. O. C. Gruner, Dr. T. Wardrop Griffith, and Mr. A. L. Whitehead.

Reviews and Notices of Books.

Mosquito or Man? The Conquest of the Tropical World. By Sir RUBERT BOYCE, F.R.S. London: John Murray. 1909. Pp. 267. Price 10s. 6d. net.

THE direful importance of flies as disseminators of disease has been fully realised for only a few years. Although the discovery of the connexion between various diseases and the presence in the body of definite bacterial organisms naturally led to the inference that these might be carried from person to person or from infected localities by flies, comparatively little weight seems to have been laid upon this just inference. The undoubted sources of danger in contaminated drinking water, milk, and other articles of diet engaged attention rather than the possible living carriers of deadly germs. It is probably the recent investigations upon malaria and the proof that the malaria organisms pass certain stages of their existence within the bodies of mosquitoes, and perhaps still more the later researches upon sleeping sickness and other diseases caused by the presence in the blood of trypanosomes, which again directed attention to the general importance of diptera as sources of other kinds of infection. For while the mosquitoes are intermediate hosts of the malaria protozoon, it is not so clear that the trypanosomes pass any stage of their existence as actual parasites of the tsetse fly; it would rather appear that they are merely conveyed by this fly from one infected animal to another until then non-infected animal. This accidental transference is believed to play a large part in the dissemination of disease; plague, for example, may be transferred through the intermediary of fleas, and typhoid fever through the common domestic fly. All of these matters are dealt with in an interesting and convincing way by Sir Rubert Boyce, who, from his connexion with the Liverpool School of Tropical Medicine, has had much opportunity of gathering accurate first-hand knowledge.

The book is meant for the layman, from whom it demands in the way of preparation for study merely that acquaintance with scientific method and progress which is now so generally diffused among the reading public. The historical method adopted by the author shows how enormous has been our progress in so complex a subject, and proves absolutely that the most important part played in the acquisition of this immense mass of information has been in the domain of zoology. And yet in the face of this patent fact the study of zoology was at one time in considerable danger of being eliminated from the medical curriculum, while it is still reduced to its lowest possible dimensions in an overcrowded curriculum. A fair weighing of the topics dealt with by Sir Rubert Boyce leaves no room for doubt as to the value of a training in all branches of

zoology. In writing on the "proof of the mosquito doctrine of malaria the author remarks: "With these facts proved it is clear that in order to prevent malaria it was necessary to protect man from the infected mosquito and also to wage war against it. Now, this latter would have been a stupendous task if it meant that war was to be waged against all mosquitoes. Here, however, direct scientific observation proved to Ross that the only species of mosquito which could become infected belonged to a single group, the Anophelinæ." Thus the capacity to distinguish species from species became a necessity, as abundant errors in zoological publications conclusively prove, for the number of ill-described and unidentifiable species which cumber the pages of zoological journals is vast. The faculty for such observation is not universal and needs development by proper training; and though the training may properly form part of a post-graduate course, early zoological instruction will make it much easier.

Given the requisite zoological knowledge, the rest of the prophylactic measures are matters of common sense. It being known that the larvæ of germ-carrying mosquitoes inhabit such and such localities, it becomes clear that they must be eliminated from these localities. The emptying of water-butts, the screening of cisterns, and, in fact, the whole series of recommendations issued for the purposes of warning the ignorant are obvious results of the technical inquiries of the expert and need no special education on the part of those whose business it is to carry them out.

The history of discovery relative to yellow fever occupies no less than five chapters of the volume under consideration. It offers an excellent instance of the persistence of views without proper support, followed by the success of practical preventive measures deduced from the scientific study of other diseases. It is a most remarkable fact that in spite of great attention to this prevalent disease by so many competent observers of several nationalities there is up to the present no knowledge whatever of the actual parasite which is concerned in the disease. As Sir Rubert Boyce justly observes: "The prevention of vellow fever is one of the most brilliant triumphs of modern prophylaxis." So long ago as 1881, while this particular branch of preventive medicine was quite in its infancy, Dr. Finlay of Havana had enunciated a theory that mosquitoes were responsible for transmitting yellow fever. Although subsequent discovery did not lead to the detection of any microscopic parasite, it did undoubtedly establish the fact that the transmitter of the disease was a definite species of mosquito-viz., Stegomyia calopus-and that while the virus was transmissible by the fly it was only after a latent period of three days that this transmission could take place. This, of course, argues a development of the parasite within the fly analogous to what happens in the case of the malaria organism. This enormously important discovery could not have been made without a consideration of the previous work upon the transmission of malaria and upon the life-history of the malaria parasite. Previous though still recent methods of dealing with outbreaks of yellow fever were directed of course to the destruction of bacterial sources of infection. The fact that the disease, at any rate during a particular outbreak mentioned by the author, was found in the houses of the wealthy as well as in the more insalubrious quarters of Belize, may have given a clue to the inefficiency of that view of the causation. The failure of quarantine in coping with yellow fever depends, of course, upon the communicability of the disease being only via the stegomyia, a fact which must have come as a shock to many brought up upon older but still very new views. The truth of the statement of the alchemist and physician, Bombastes Paracelsus, that

disease comes from without and is not engendered within, is more than ever established.

It is perhaps remarkable that Sir Rubert Boyce only devotes a part of one chapter to sleeping sickness, in view of its bulking so largely in the public view at the present moment, as well as in view of the important theoretic question that it gives rise to. The Sleeping Sickness Committee housed by the Royal Society is extremely active in this matter and has been for some time. The numerous papers which have been sent home and are published, or to be published, in the Proceedings of the Royal Society by Sir David Bruce, now actively engaged in the investigation of the parasite of this disease, as well as the continuous work in this country of Mr. H. G. Plimmer and others, are resulting in a very detailed knowledge of the various trypanosomes which are the cause of this and some other allied diseases. While much is known of "trypanosomiasis" much is yet involved in mystery. It is not at all certain how far the trypanosome⁸ actually live as parasites in the tsetse fly or whether, as already mentioned, they are merely conveyed from man to man or from beast to man in a mechanical way by the fly. Furthermore, the life-history of the protozoon requires clearing up. There is, for example, some evidence that it propagates itself at times by ultramicroscopical spores. Many years ago Dr. Dallinger, whose recent death we deplore, in cooperation with the late Dr. Drysdale, found that free living monads, allies of trypanosoma, divided into an immense number of excessively minute spores which could not be properly observed with the poorer lenses of the early "seventies." It is quite likely that the same phenomena occur in the parasitic forms which, moreover, may be conceivably parasitic stages of free living organisms, thus complicating the problem still further. Apart from prophylaxis Sir Rubert Boyce advocates arsenisation as the most effective treatment. In any case, as in other diseases conveyed by protozoon organisms, it is prophylaxis rather than treatment after infection that promises the best results.

This very interesting volume cannot fail to bring home to the reader the vast importance, economic as well as scientific, of this new "conquest of the tropical world." The text is elucidated by numerous plates from photographs which illustrate not only several of the insects concerned in the propagation of disease, but views of "anti-mosquito brigades," screened wards in hospitals, houses in course of fumigation, and many other scenes and objects bearing upon the contents of the book.

The Physiological Feeding of Infants. By ERIC PRITCHARD, M.D. Oxon., M.R.C.P. Lond., Assistant Physician to the Queen's Hospital for Children. Third edition. London: Henry Kimpton. 1909. Pp. 469. Price 7s. 6d. net.

This was a good book in its first edition; it is a much better book now. The first edition was written round the subject of the "modification" of milk, which was five years ago a comparatively new process, originally devised by Meigs in America. The chapters on the need of modified milk still remain, but much new matter has been added to them, and the volume has gained some important chapters on conditions of malnutrition in infants which reveal a wide experience and sound clinical judgment on the part of the author. The whole book is admirably written; it is polished in style, yet not formal; simple, and yet accurate. To an intelligent. educated mother or nurse the directions for the artificial modification of milk would be quite intelligible, and the methods could easily be followed from the directions. Much of the clinical description could also be comprehended by an intelligent laity, so that if not too much reliance were

placed upon it alone the volume would be a useful manual in the nursery, though it is properly directed towards informing the medical profession. Especially valuable would be the sections on the modification of food in obedience to the hints afforded by symptoms of abnormal digestion.

We are glad to find the author opposing the indiscriminate use of predigested or peptonised milk. It has its value in acute gastro-intestinal derangements or for short periods of time, but it deprives the infant's stomach in health of the opportunity of learning to exercise its natural functions. It is impossible to insist too strongly on the value of fresh milk; the more milk is manipulated and handled the more it loses some subtle quality, partly due to the destruction of proteolytic and fat-splitting ferments. Dr. Pritchard places no faith in any form of dried or condensed milk. Our knowledge of the proteid constituents of milk is, however, far from complete, and the usual modern classification of caseinogen, lactalbumin, and lactoglobulin indicates only widely groups capable of being split up into numerous smaller varieties.

The practical details of milk modification deal with the alteration of the percentage ratio of fat (afforded by cream). milk sugar, proteids, and water. Modifications of the ordinary percentage of average cow's milk have been effected in a rough-and-ready fashion in nurseries since "bottles" were first used, but they have been much confined to additions of water, milk sugar, and occasionally cream. The teaching of Dr. Rotch and the practical working of the Walker Gordon laboratories have reduced the percentage reconstruction of milk almost to a certainty, but not quite. It is comparatively easy to separate cream and milk and reassemble them with any given percentages of fat and caseinogen, adding water, or cream, or milk sugar as required, but to prepare "split proteid" mixtures is a more subtle matter. It consists, in general terms, in preparing whey from separated milk by means of rennet, heating the whey to 140° F. to destroy the activity of the ferment, and adding cream and milk sugar. The factors involved in the reconstruction of milk, in which "split proteids" are concerned, are grouped for practical purposes as caseinogen, whey proteids, and fats, and the laboratories which undertake the "reconstruction" of milk are now prepared to issue milk re-formed in percentages of these constituents. Dr. Pritchard lays stress on the necessity of employing these "split proteids" in occasional cases of young or delicate infants, but the highly elaborate calculations and processes required by the employment of split proteids are seldom required and should not deter medical advisers from gaining a knowledge of simple methods. It is unnecessary to summarise the directions for the modification of milk, as it can be carried out in an ordinary nursery. The procedure is no more difficult than that involved in the construction of an ordinarily edible pudding, and the description of the processes as given by Dr. Pritchard is lucid, minute, and simple. He prefers a modification of Soxhlet's apparatus, which would cost about 15s., but having a large experience among the poorest classes he is fertile in suggesting cheap substitutes for expensive apparatus. And not only in apparatus is he mindful of the empty pocket of the poor. There is no doubt that many infants among the poorer classes suffer from lack of cream in cows' milk diluted to furnish a lower proteid percentage. He therefore recommends the addition to each bottle of a small quantity of a solution of citrate of sodium to delay the coagulation of the caseinogen, and to supply the deficiency of fat he employs (for the poor) emulsions of cod-liver or salad oil, or even linseed oil. An emulsion of the

last can be made at a cost for materials which will furnish nearly a hundred feedings for 4d. It is impossible to note more than a small fraction of the many excellent points of detail in these chapters on milk; they are so careful and clear that everyone interested in or employed in the management of crèches or babies' homes should obtain this volume. There are admirable information and advice on the subject of breast-feeding, a function which is usually performed in a very perfunctory manner. Even accoucheurs and nurses of the widest experience might find something new to them in this chapter. The importance and methods for regulating the rate of sucking are properly insisted upon, and great stress is laid on the value of test-feeds estimated by weight. Very careful attention is also given to the recognition of the effects of the over-supply or under-supply of breast-milk.

Dr. Pritchard has compiled a mass of information based upon new work by Emil Fischer and other organic chemists on the digestion of the carbohydrates in the intestinal tract. As he says, our whole conception of this subject has recently been greatly modified and simplified. After reviewing the physiological chemistry of the carbohydrates which enter most largely into the constituents of food, the author traces very clearly the influence on babies of feeding them too early with carbohydrates, and arrives at the conclusion that "starch given at this early period of life is digested, but it is digested in the wrong way, in the wrong place, and by the wrong agencies." Instead, therefore, of being broken down by the amylopsin ferment in the duodenum, it is attacked by bacteria in the colon and broken down into irritating acids, such as acetic, butyric, and valerianic acids, and into gases such as hydrogen, methane, and carbon dioxide. We can conceive no better tribute to the author's style of writing than that he has rendered a disquisition on such a subject not only easily intelligible but extremely interesting to read. The end of the volume contains some excellent recipes for preparing foods for children which are careful and not too abstruse, while the ingredients can be obtained at moderate cost. Directions for making the emulsions to which we have alluded are given here.

Gail-stones, their Complications and Treatment. By A. W. MAYO ROBSON, D.Sc. Leeds, F.R.C.S. Eng., and P. J. CAMMIDGE, M.D. Lond. London: Henry Frowde and Hodder and Stoughton. 1909. Pp. 315. Price 5s. net.

THE works issued under the title of the Oxford Medical Publications have comprised several valuable additions to current medical literature. The volume before us may confidently be said to be at least as valuable as any of its predecessors. Time was when the treatment of gall-stones was purely medical; now the conditions are changed, and all agree that gall-stones should be treated early by the surgeon if the best results are to be obtained, and the parts of this volume which include the operative treatment of gall-stones are among the most valuable.

The chapter on the anatomy of the gall-bladder consists of an account of the structure of these parts, which, while it cannot be called elaborate, is adequate for the purpose for which it is intended. The authors divide the common bileduct into four portions: (1) the supra-duodenal; (2) the retra-duodenal; (3) the pancreatic; and (4) the intraparietal. The various forms which the ampulla of Vater may present are illustrated by a diagram, and this will help to demonstrate the differences that exist in different cases in the risk of a gall-stone lodging there in its course towards the duodenum. The authors appear to think that the linguiform processes of the liver or Riedel's lobe may be acquired. They mention that "it is said to be uniformly due to cholelithiasis," but they agree that it is not always associated with gall-stones. It is, however, extremely doubtful

if it is ever really produced; it is probably always congenital.

An account of the character and composition of bile follows, and this is succeeded by a chapter on the composition and formation of gall-stones, and some excellent figures illustrate this occurrence. The bacterial origin of gallstones is described, but we do not obtain any authoritative statement as to the relative frequency with which different organisms act as causative factors. It is suggested that a proteid diet in excess has but little tendency to the formation of gall-stones. The various symptoms of cholelithiasis are detailed and discussed. With regard to the law usually associated with Courvoisier's name, that distension of the gall-bladder accompanied by jaundice is usually dependent upon malignant disease, either of the head of the pancreas or of the common bile-duct, and is rarely associated with gall-stones, it is pointed out that one of the authors, Professor Mayo Robson, had drawn attention to this association previously to Courvoisier's publication, but it would be difficult at present to change the name of the law. As is pointed out here, the absence of dilatation of the gallbladder which usually accompanies the presence of gallstones is due partly to the ball-valve-like action of the stone not causing complete obstruction, and partly to the inflammatory changes set up by the calculi, by which the gallbladder is frequently diminished in size as it become adherent to surrounding structures, so that when the common duct is later obstructed the gall-bladder is unable to dilate.

In the diagnosis of gall-stone the point on which most stress is laid is the paroxysmal nature of the attacks of pain, and the presence of very marked tenderness over the region of the gall-bladder, or at least over some point in a line from the ninth costal cartilage to the umbilicus. Slight jaundice is very frequently present in gall-stone colic, even when the calculi are merely in the gall-bladder or cystic duct. We agree thoroughly with the authors that in doubtful cases the operations of sounding for gall-stones and of aspirating distended gall-bladder are not only futile but dangerous. A small exploratory incision is far safer and of much greater value whether for diagnosis or for treatment. The pancreatic reaction of the urine may sometimes prove very useful in doubtful cases. The complications of gall-stones are many, and the authors tabulate 27, though it would have simplified matters if they had been grouped; they range from dilatation of the stomach to infective endocarditis. The pathological changes in the gall-bladder and ducts are well described, and the authors maintain that drainage is the best treatment for suppurative cholangitis. As the authors point out, intestinal obstruction due to gall-stones may arise in four ways: firstly, there is simple mechanical occlusion caused by a large stone; secondly, obstruction due to volvulus dependent on the violence of the colic caused by gallstone attacks; thirdly, obstruction resulting from adhesions left by local peritonitis; and lastly, obstruction dependent on paralysis of the intestine caused by peritoneal adhesions. Inasmuch as 52 per cent. of these cases are fatal when treated on medical and expectant lines, it is clear that surgery should be resorted to at an early period, and an operation should be performed as soon as symptoms of obstruction occur. We concur in the advice that enterotomy is far preferable and safer than any attempt to crush the stone without opening the bowel wall; and, of course, it is hardly necessary to point out that the mortality resulting in these cases when surgical intervention has been left to a late period of the disease cannot be taken as any indication that surgical treatment is as likely to be followed by fatal results as is medical treatment.

An interesting chapter is that on malignant disease. In a series of 56 operations for cancer of the biliary passages, 41

—that is, 73·2 per cent.—were associated with cholelithiasis, and even in several of the other 15 a history of long-continued attacks of intermittent pain pointed strongly to a similar association. The authors are inclined to support the theory that the "irritation" of the gall-stones leads to the occurrence of malignant disease. Calculi in the common bile-duct were said to occur by Courvoisier in 4 per cent. in all cases of cholelithiasis, but the authors have found this condition present in nearly 40 per cent. of their own cases of gall-stone.

A chapter is devoted to medical treatment, though it is pointed out that medical treatment is essentially preventive and not curative; but this preventive treatment should be of great value in diminishing the tendency to recurrence of stone in those who have already suffered from this affection. It is advised that the meals should be regular and at frequent intervals, and a mixed diet is, we are told, best; but overindulgence in sweet or starchy foods should be avoided. It is especially urged that care should be taken that a sufficient amount of water should be drunk so that the bile may not run the risk of becoming concentrated. The authors do not believe that it is possible, by any drug administered by the mouth, to cause the absorption of stones already present in the biliary passages, but they think that some drugs, such as benzoate of soda, which have been reported as having a beneficial effect, may act by relieving the associated catarrh. They are quite sceptical as to the value of olive oil in causing the passage of gall-stones, and any effect it may have they ttribute partly to the lubricating action on the bile-duct and partly to the diminution of the excessive secretion of hydrochloric acid in the stomach.

As to the operations on the biliary passages, they urge the value of pushing the spine forward at the level of the liver and depressing the lower part of the body, so that the common and cystic ducts are brought several inches nearer the surface. As to the question which has within recent years been raised of the desirability of excising the gall-bladder in all cases where surgical intervention is desirable, the authors are opposed to it, for the results they claim of cholecystotomy are so good that they consider that it is unnecessary to remove the gall-bladder unless there is some special indication for it, while if the surgeon is not perfectly certain that the lower biliary passages are quite free the risks of cholecystectomy are very great.

This is a valuable book, for it contains in a convenient and readable form all the accepted knowledge on the subject.

Folkssenchen (Epidemio Diseases). 14 lectures. By various authors. Edited by Professor Dr. R. Kutner. Jena: Gustav Fischer. 1909. Pp. 390. Price M.6.

THE series of lectures contained in this book are part of a course of what we should call post-graduate instruction, delivered under the direction of the Zentralkomitee für das aerztliche Fortbildungswesen in Preussen. An introductory address by Professor M. Kirchner deals with epidemics in general and emphasises the amount of human life which they are responsible for destroying. In the second lecture Professor A. Wassermann gives a brief outline of our present knowledge of immunity and of the principles of serumtherapeutics founded upon it. Later in the book this same writer deals with enteric fever, chiefly from the bacteriological point of view, describing the methods of identifying the bacilli, the Widal test, and the unsuccessful attempts so far made to treat the malady by specific methods; and in the last lecture but one he also writes on small-pox and vaccination. While in respect to this last disease Germany is specially well protected by reason of a scientific insistence upon universal vaccination, in regard to other epidemics, such as dysentery,

plague, cholera, leprosy, and hydrophobia, the land frontiers of the country render it more exposed than are these islands to recurring outbreaks. The fear of the introduction of plague seems from these lectures to be ever present, and two lectures are devoted to this subject, one by Professor W. Kolle on the clinical features of this protean affection, and a second by Professor G. Sticker on diagnosis. The former is specially interesting as giving a graphic account of the malady, which is very well worthy of study. Dysentery is dealt with by Professor Kruse and cholera by Professor W. Kolle. Two lectures deal with tuberculosis, one by Professor W. Dönitz on the treatment of the affection, and the other by Professor A. Moeller on the public health and sanatorium aspects of the question. The former writer regrets that there is no method of measuring the degree of immunity produced by injections of tuberculin, and makes no mention of the determination of the opsonic index, which strikes us as an extraordinary omission. Opinion may differ as to what the value may ultimately prove to be of some of the work done in this direction, but this point makes that work more certainly deserving of record and criticism. We find sometimes that appreciation of the work of foreign observers is not a strong point in German science. Yellow fever, sleeping sickness, and beri-beri are described in one lecture by Dr. B. Nocht, and malaria in another by Professor E. Martini. The latter gives some useful illustrations of the anopheles and culex genera of mosquitoes and of their larvæ. Professor M. Kirchner's lecture on leprosy is interesting, as giving an account of the development of humane treatment of this disease, and also as pointing out its wide prevalence even at the present day, when our own immunity from it leads to a disposition to minimise its importance elsewhere. The final lecture by Dr. Schüder on hydrophobia may be studied with advantage as affording a good account of the measures taken in Germany to deal with outbreaks of the disease, although the immunity which has been obtained in this country renders any imitation of them here unnecessary.

In the above account we have not kept to the order of the actual chapters. It will be seen that the volume does not contain a complete account of all infective diseases, but a series of articles on certain selected examples. These are from the hands of experts, and are clearly written and of definite value. We understand from an editorial note that other volumes in this series are to follow, and we shall look forward with interest to their appearance in view of the excellence of the present book.

The Ophthalmic Year-Book. Edited by Edward Jackson, A.M., M.D., George E. De Schweinitz, A.M., M.D., and Theodore B. Schneideman, A.M., M.D. Volume VI. Denver, Colorado: The Herrick Book and Stationery Company. 1909. Pp. 415.

THE "Ophthalmic Year Book" is an American publication containing a digest of the literature of ophthalmology of the year. It has now reached its sixth volume, and each succeeding volume has been an improvement on its predecessor. It is published under the editorship of Dr. Jackson, Dr. de Schweinitz, and Dr. Schneideman, names which are guarantees for the excellency of the publication. In fulness and detail it scarcely competes with Nagel and von Michel's "Jahresbericht für Ophthalmologie," but it has the inestimable advantage of appearing within a few weeks of the end of the year which is being dealt with. Its utility is enormously enhanced by this fact, and, as far as we have been able to judge, it gives a remarkably complete and accurate résumé of ophthalmological literature. The book is divided into three sections. The first gives short biographical sketches of ophthalmologists who have died

during the year; the second, comprising the bulk of the book, gives a classified digest of the literature; and the third gives the list of the books, transactions, and journal articles, with extensive references to the places of publication. It will suffice to say that the abstracts from the papers and other publications have been satisfactorily carried out, not only with regard to American literature, which naturally occupies a prominent place, but also with regard to English, German, and French. We consider it a book which no ophthalmologist can afford to be without.

LIBRARY TABLE.

First Principles of Chemical Theory. By C. H. MATHEWSON, Ph.D., Instructor in Chemistry and Metallography at the Sheffield Scientific School of Yale University. London: Chapman and Hall, Limited; New York: John Wiley and Sons. Pp. 123. Price 4s. 6d. net.—This book is quite advanced in the treatment of its subject, in spite of which it presents the first principles of modern chemical theory in plain and intelligible terms to the beginner. The author however, very properly does not expect the reader to confine himself to theoretical considerations, for he distinctly states that the purpose of the book is rather to offer a very early presentation of leading principles which are of material assistance in teaching the beginner to explain and correlate his experimental results. In the plan of teaching adopted at the Sheffield Scientific School of Yale University the aim is to improve every opportunity for illustrating and applying the principles discussed as the student adds to his actual chemical experience. That is an admirable plan. The author justifies the introduction of the electrolytic dissociation theory and the law of mass action at an early stage, and, in fact, includes such considerations in the first year of study. We agree with him that, having regard to the importance of these questions in all chemical studies, they should receive attention as soon as possible, and if the student's practical course is directed to a demonstration of chemical changes and the theoretical considerations which they involve he is calculated early to realise the meaning and significance of ions and so forth. The modern interpretation of chemical change and reactions is thus well put, and the book should be not only of distinct service to students, but to others who, while they have studied chemistry under the old régime, would be glad to keep pace with recent developments.

Guy's Hospital Nursing Guide, 1909. Edited by the MATRON. London: Ash and Co. Pp. 166. Price 1s. 6d. -This is the fifth issue of the register of nurses of Guy's Hospital. To it is appended an excellent essay on Nursing as a Profession, and 40 pages of valuable information on various points connected with a nurse's duties, such as the handling of infectious cases, the immediate treatment of poisoning, and other subjects, all well arranged and sound in matter. There are some very good receipts for invalid cookery. Those contemplating nursing as a career would find this unassuming volume a valuable guide.

Iransactions of the American Otological Society. Fortysecond Annual Meeting. New Bedford, Massachusetts: Mercury Publishing Co. 1909.—The first paper in this volume of transactions has been contributed by Dr. Crackett. It deals with the treatment of acute suppurative lepto-meningitis of otitic origin, and is based upon six cases operated on by drainage. The second paper is by Dr. Norval H. Pierce and is a report of a case of recovery after an operation on a large cerebellar abscess, in which the patient exhibited nystagmus towards the sound side with the caloric test on the sound side, and on the diseased side a negative result was obtained. Dr. Dench reports two cases of abscess of the brain, one of them terminating in recovery. Syphilis of the Ear, by Dr. J. S. Fraser, being Part 2 of the

A paper read by Dr. P. Fridenberg on some recent theories of the labyrinth will well repay careful perusal. An article on subjective and objective sense of sound perception by Dr. D. B. Kyle is a well prepared paper. Dr. J. B. Ras reports two cases of Sinus Thrombosis. Dr. A. B. Duel and Dr. J. Wright contribute a paper on the Clinical and Pathological Significance of Bacterizenia in Suppurative Otitis; it contains a large amount of exceptionally interesting matter. Dr. G. E. Shambaugh read a paper on the Significance of Certain Labyrinthine Symptoms. Dr. W. C. Braislin presented: (1) a paper on a Study of Some Casts of the Infantile Pharynx, with special reference to the Eustachian Tubes; and (2) a Note on Eustachian Obstruction, together with a long bibliography. The remaining memoirs which complete the volume are as follows: Autotoxic Deafness, by Dr. S. F. Snow; Nasal and Aural Discharge in Children, by Dr. P. Fridenberg; Sequestrum of Labyrinth, by Dr. J. F. McKernon; the Importance of the Thorough Study of the Naso-pharynx in the Treatment of Diseases of the Ear, by Dr. J. R. Packard; Chronic Epipharyngeal Periadenitis. in Adults, by Dr. J. S. Logan; Report of a Case of Removal of Foreign Body from the Region of the Tympanic Cavity, Entrance through Soft Palate, by Dr. D. A. Walker; and Radical Removal of the Tonsil, by Dr. C. W. Richardson.

Annals of Otology, Rhinology, and Laryngology. St. Louis, Missouri: J. H. Parker. June, 1909. Price \$4.00.-This volume contains papers read at various meetings of societies in the United States, the first being by Professor Chiari on the Treatment of Cancer of the Larynx; and the next, admirably illustrated by Dr. Loeb, is a Study of the Anatomical Relations of the Optic Nerve to the Accessory Cavities of the Nose. These are followed by several other good papers. The first original one is by Dr. L. M. Hurd and Dr. J. Wright upon the Diagnosis of Tuberculosis of the Tonsils, Clinical and Microscopical; the next being on the Removal of the Entire Tonsil by F. C. Todd. A Method of Precision for Inflating the Tube and Tympanum is the title of a short paper by Dr. J. Hubbard; and Dr. D. Day reports a case of probable sarcoma of the temporal bone. A few abstracts on current literature are also included.

Christmas and New Year Cards, Sc. - From Messrs. Raphael Tuck and Sons, Limited, Moorfields, London, E.C., we have again received a selection of Christmas and New Year greeting cards, pictorial calendars, and toy books for children, of infinite variety, artistic design, and excellent workmanship. We have for so many years past spoken in terms of high commendation of the productions of Messrs Tuck, that it is difficult to find new words with which to express our approval.

JOURNALS AND MAGAZINES.

The Manchester Medical Review .- Two articles on the relations of the medical profession and the public appear in the October issue of this magazine. One by Dr. J. Stavely Dick deals with the organisation of the profession from within and acclaims the British Medical Association as "a type of machine for such a purpose which cannot be surpassed." The other, written by Dr. E. Vipont Brown, draws attention to the evils of dispensaries and sick clubs, and regards the scheme propounded by the Minority of the Poor-law Commission as affording a suitable remedy. Dr. G. H. Lancashire contributes an interesting paper on Dermatitis Artifacta, and Dr. S. English deals with the subject of Strangulated Hernia and records three illustrative cases.

Journal of Laryngology. Rhinology, and Otology. August, September, October, and November, 1909.—The August number of this journal contains a paper on Congenital

report for the Ear and Throat Department at the Royal Infirmary, Edinburgh. In the September number there is a paper by the same author on the Histology of Nasal Accessory Sinus Suppuration. Otherwise the issues consist mainly of transactions of societies, with a few abstracts from current literature.

New Inbentions.

A NEW ÆSTHESIOMETER.

THE instrument which I here describe is by no means presumed to be indispensable, but it is capable of filling a want in the armamentarium of the neurologist, who often has to make a series of examinations of sensibility in a relatively short time. The utensils required occupy only a small space; the case may be easily carried in the coat pocket. One can work quickly with it and yet get very exact results. I consider it a special advantage to be able to trace immediately the limits of sensation and to have one hand free during the determination of the sensibility to contact, pressure, and pain, although both hands are in use in the delineation of the limits of sensibility to temperature. The case contains two instruments:

1. One of these is slender, shaped like a penholder, and covered at both ends with caps which are removeable by simply pulling them off. A camel's hair pencil may be placed on the end of one of these caps; it is used for testing tactile sensation. Removing the cap reveals a needle; this serves to test the sensibility to pain. This needle may be heated to redness before each examination without blunting its point in the least. The other cap encloses a dermatograph. Between the latter and the needle lies a spring, the strength of which may be graduated in three different degrees by means of weights. As a rule this spring is tight. Its simple tightening mechanism is loosened by a slight turn to the left; this enables us to test the sense of pressure by placing on the skin either the dermatograph or the cap

which covers the needle, then compressing the spring. When for this purpose the needle is used it is easy to graduate the irritation of pain by compressing the spring, just as with Aly's instrument. With this part of the æsthesiometer we may also test the tactile sensibility, as well as that of pain and pressure, while simultaneously tracing the obtained limits.

2. The other instrument is broader and serves to examine the sense of temperature. It consists of three parts: two hollow metallic cylinders, separated by a solid rubber cylinder, which serves both as handle and isolater. The metallic cylinder which lies nearer the corrugation in the rubber handle is filled with sodium acetate, like a thermophore. This salt, as is well known, melts on being heated a short time over the flame of a spirit lamp or any other, communicating the disengaging heat to the surrounding parts; it recrystallises on cooling. may therefore be used a considerable number of times without renewing. With

this part of the instrument we test the sensitiveness to heat. The other cylinder serves to test the sensation of cold; for this purpose the natural coldness of the metal alone may be used (which generally suffices in winter), or the cylinder may be filled either with cold

water or with lumps of ice. Experiments made in the Frankfort Physical Society by a chemist, Dr. W. Epstein, and myself have shown that for tests with high degrees of cold-which seldom come into consideration, since intense cold, just as excessive heat, acts more like an irritation of pain—ammonium nitrate is the most suitable material. It is cheap, may be had in large crystals, and easily introduced into the cylinder. It is only necessary to add a little water and the nitrate dissolves immediately, giving out intense cold. But it does not recrystallise spontaneously; a new filling is therefore required before each examination.

Experiments have determined that the differences in temperature may be plainly recognised by healthy persons during about 15 minutes, even when the cylinder is only filled with cold water; this time is amply sufficient, even for very minute tests of the sense of temperature. Both metallic cylinders are closed by screwing the caps on tight; thus the cold and the warm side may be applied alternately and continually without danger of leakage. It is obvious that this method of examination is much easier than the one generally used with several test-tubes of different temperature, not to mention the greater facility in the transportation of our instrument and the advantage of being able to trace with the dermatograph the limits obtained.

This instrument may be obtained from Mr. B. B. Cassel, Neue Zeil, Frankfort-on-the-Main, price M.15, case included.

DR. SIEGMUND AUERBACH.

MEDICINE AND THE LAW.

A Foolish Libel on a Medical Inspector of Schools.

Dr. Martha Adams, a lady who in July, 1908, was appointed medical inspector of schools in the district of Twickenham, recently brought an action for libel against Vanity Fair, Limited, Pomeroy, and others, in respect of an article written by the defendant Pomeroy, and published over his signature in Vanity Fair. The action when the case came on for trial had been stayed against all the defendants except Mr. Ernest Pomeroy. The evidence showed that acting in her official capacity the plaintiff found two girls in a school under her care had not been vaccinated, in the case of one of whom a certificate of exemption did not appear to have been obtained. The plaintiff thereupon gave notice of this to the vaccination officer, a course which was not prescribed by the circular of the Board of Education defining her duties, and with regard to which a question in the House of Commons elicited the reply from the President of the Board that information so obtained should be regarded as strictly confidential. The defendant wrote of this incident in Vanity Fair, "To my mind a more villainous misuse and abuse of power has never been perpetrated even in the medical profession, which is peculiarly prolific in devices of this kind. But why are the medicoes so prejudiced? Because of the vaccination fees! How many of the children reported to the vaccination officer by Dr. Martha were subsequently infected by her, and at how much per head, or, if by some other doctor, what percentage of fees did she obtain?" Apparently the fact that the plaintiff had exceeded the strict limits of her official duties in what she did affected the view of the jury. At all events, they were content to find a verdict for one farthing damages, for which judgment was entered with costs. An appeal published in another column (see p. 1854) should ensure Dr. Adams's personal loss being amply covered. It need hardly be mentioned that Dr. Adams, in the witness-box, stated that she had never vaccinated a child in Twickenham, or suggested that one should be vaccinated, and that her remuneration was by salary unaugmented by fees for examining or reporting on children and that no contradiction of this was attempted.

Typhoid Fever from Eating Oysters.

An action was recently tried before the Lord Chief Justice and a special jury in which the plaintiff, Leslie Cardale, a lieutenant in the Royal Navy, sued Henry Klockenbusch, a hotel keeper at Chatham, for negligence in supplying him with oysters at dinner from which he contracted typhoid fever. A brother officer, like himself in command of a torpedo-boat destroyer lying off Sheerness, who dined with the plaintiff on the night when the oysters were alleged to have been eaten, had also been taken ill with typhoid fever and had died. The plaintiff was the only witness as to the fact of his having eaten oysters at the defendant's inn on the night alleged, his companion being dead, and the fact that he had eaten them being denied by the defendant whose books did not show that any oysters had been supplied to customers on the day named. Ample medical evidence was, however, given as to the illness of the plaintiff, as to the dates on which both officers were first medically attended, as to the normal period of incubation of

the disease, as to the absence of other cases in the fleet, as to the nature of the contamination of oysters, and as to its The medical officer of health of Chatham also deposed to the fact that certain areas in the Medway were liable to be infected by sewage from Rochester and Chatham, and that oyster beds had been closed by order of the Fisheries Commission. The chamberlain of the Rochester fisheries was also a witness with regard to the contamination of certain beds which he specified, in the neighbourhood of Chatham and the steps taken to prevent dredging from them. It was contended on the part of the defendant that he had taken all reasonable care and that it was not proved that the illness of the plaintiff was due to his having eaten oysters on the date alleged at the defendant's house. The questions left by the Lord Chief Justice to the jury were as follows: "Did the plaintiff contract typhoid fever from any oysters supplied by the defendant! Did the plaintiff rely on the skill and judgment of the defendant to supply him with fit and proper food? Assuming that the oysters were supplied by the defendant to the plaintiff, was the defendant, or were his servants, guilty of negligence?" The above questions, upon which the liability of the defendant was held to depend, were all answered in the affirmative by the jury, and as this constituted a finding for the plaintiff, a verdict as to the damages was added-namely, £264, to include £100 in addition to the "special damages" claimed. The latter were made up of expenses of medical treatment and of loss of pay due to the illness. Judgment was given for the above amount, a stay of execution being granted subject to the money being paid into court.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEETING OF COUNCIL.

An ordinary meeting of the Council was held on Dec. 9th, Mr. BUTLIN, the President, being in the chair.

A report was read from the Board of Examiners in Anatomy and Physiology for the Fellowship, stating that at the recent examination 108 candidates were examined and that 33 of these were approved and 75 rejected. It was resolved to issue Diplomas of Fellowship to 28 successful candidates. It was resolved to issue diplomas of the Licence in Dental Surgery to 36 successful candidates.

Certain alterations in the regulations for admission to the museum, recommended by the Museum Committee, were approved and adopted. The most important change is that women holding other medical or surgical qualifications than those of the College, and women medical students desirous of admission to the museum on other days than Friday or Saturday, must make application in writing to the secretary or conservator. The application must be accompanied by a letter from the dean of the applicant's medical school in the case of a medical student, recommending that a ticket of admission be granted. Tickets of admission, which are not transferable and must be produced on application before admission, are granted for six months; at the expiration of this time application must be made for their renewal.

Mr. J. F. Colyer was appointed honorary curator of the odontological collection.

On the recommendation of the Committee of Management it was resolved to add the London School of Medicine for Women and the Edinburgh School of Medicine for Women to the list of recognised medical schools, and to add the Royal Free Hospital to the list of recognised hospitals; it was also resolved to recognise the public health laboratories of the School of Medicine of the Royal Colleges of Physicians and Surgeons of Edinburgh for the course of instruction for the diploma in public health. These recommendations require also the approval of the Royal College of Physicians of London

It was resolved to address a communication to the Privy Council urging the need for early legislation to give effect to the recommendations of the Departmental Committee appointed to consider the working of the Midwives Act of 1002.

Mr. H. F. Waterhouse was elected a member of the Court | T. H. Havelock and J. A. Smythe. The Council of Durham of Examiners in the vacancy occasioned by the retirement of | Colleges: H. E. Ferens, W. R. H. Gray, and Rev. J. P. Day.

Mr. Bernard Pitts. Dr. G. F. Blacker was elected an examiner in midwifery under the Conjoint Examining Board in the vacancy occasioned by the death of Dr. W. R. Pollock. Mr. R. J. Godlee was appointed a representative of the College on the Senate of the University of London in the place of the late Mr. H. H. Clutton. Mr. A. Pearce Gould was elected a member of the Executive Committee of the Imperial Cancer Research Fund in the vacancy occasioned by the death of Mr. Clutton.

The best thanks of the Council were given to Mr. Bernard Pitts for presenting to the College an instrument cabinet made and used by the late Sir William Fergusson, Bart.

A letter was read from the Medico-Psychological Association of Great Britain expressing its sense of "the urgent necessity of post-graduate teaching in psychiatry in medical schools and for the granting of a special diploma to candidates after examination," and asking the Universities and other examining bodies to take these matters into consideration. The letter was referred to the Committee of Management for consideration and report.

A letter was read from Sir Henry Morris, Bart., reporting the proceedings of the General Medical Council at its late session. The best thanks of the Council were given to Sir Henry Morris for his services as the representative of the College on the General Medical Council.

THE JOHN HERBERT WELLS FUND.

THE following is the sixth list of subscriptions to the John Herbert Wells Fund. Further contributions will be gratefully received by the Earl of Dalhousie and Mr. Julian G. Lousada, honorary secretaries and treasurers of the fund, at 16, Old Broad-street, E.C., or by ourselves at this

University of Durham.—A Convocation was held in the Castle Hall, Durham, on Dec. 7th. The Chancellor (Dean Kitchin) presided, and there was a large attendance of members of Convocation. Numerous ordinary degrees in arts, science, and letters were conferred, while an honorary D.C.L. was given to Mr. James Bell Simpson in recognition of his efforts on behalf of scientific education in the north during the past 40 years. The Convocation was largely interesting in that it was the first held under the statutes of the new Durham University Act of 1908. The Chancellor asked that he might be allowed to say a few words on this special occasion. He could look back on the history of the University since 1834, the date of his earliest recollection of the city and University of Durham. He briefly sketched the history of the outlying colleges, of science and medicine, which came to be a part of the University in the early "seventies." He spoke further of the desirability of keeping up the standards of entrance and other examinations, and foretold a bright future for this centre of education in the north. Principal Jevons (Hatfield Hall) also made some appropriate remarks, and mentioned the coincidence that the first birthday of their new University was the eighty-second birthday of the Chancellor. Following this was the election of members of the new Senate, the result being :- For the Durham Division : Dr. Gee (Master of University College), Principal Moulsdale, H. E. Ferens, and W. R. H. Gray. College of Medicine (Newcastle): H. B. Angus and R. A. Bolam. Armstrong College (Newcastle): T. H. Havelock and J. A. Smythe. The Council of Durham

THE LANCET.

LONDON: SATURDAY, DECEMBER 18, 1909.

The Medical Curriculum of Edinburgh University.

On another page we print a summary of the report on the medical curriculum at the University of Edinburgh, the work of a committee appointed by the Edinburgh Pathological Club to inquire into the question of the present curriculum and the general efficiency of the school. The summary may well be read in connexion with the series of articles which we are now publishing on medical education, to which it forms an interesting supplement. The committee spent many months over the inquiry, and several evenings were devoted to the discussion and final adjustment of the committee's report by the club itself. The meport has thus a somewhat unique value as emanating from a body which represents in its active membership most of the younger workers in the Edinburgh school, and with which the more senior workers retain their connexion even though they do not attend the ordinary meetings. The question of medical education has of late been much discussed largely owing to the establishment of new universities in important English centres with a freedom of action unknown to Edinburgh and the other Scottish universities. These young rivals, not new as schools but new as degree-granting centres, have had practically a free hand to organise their medical teaching on the most modern lines, while their endowments have enabled them to make the standard of medical education as high as was deemed to be desirable. In the case of Edinburgh and the other Scottish schools the methods of imparting instruction are based on foundations going deep into the past, however much the instruction imparted may represent the best and the newest knowledge. Edinburgh has, moreover, in its extra-mural school an institution which is unique, for nowhere else, even in Scotland, has extra-mural teaching the status, prominence, and power which it has long held in the capital. The extramural school has often been the first party to adopt new plans and new methods; while the University necessarily represents the conservative party, although in either camp men of extreme views may be found.

Not only do time-honoured methods of instruction tend to persist, but some of the more scientific subjects of the curriculum, in which great advances have been made, have a place given to them by their professors which is out of proportion to the time needed for the final subjects, and this must be recognised as an inevitable result of a traditional method of administration to which the modern appellation of "watertight compartments" is applicable. So much has to be said in explanation of the position in which Edinburgh at present stands and of the criticism which the report with which we are dealing passes upon the school, as represented by the University. The one question which both

parties have at heart is, How are students to be trained so as to fit them for the practice of healing in the community? For men who aspire to a university degree in medicine there can be no question that they should have an appreciative acquaintance with the earlier scientific subjects of the curriculum. Seeing that it is impossible to acquire a full knowledge of any of these subjects in the time available, it is in the highest degree important that attention should be concentrated on the aspects of the various subjects which are necessary for the intelligent and accurate understanding of clinical phenomena, while the practical work should be of a kind that will be an aid to the investigation of the conditions with which clinical medicine deals. We have on many occasions expressed our agreement with the principles. suggested in the report of the coordination of the earlier medical studies and their teaching with a direct view to their future application. This is especially the case with chemistry, physics, and physiology. The teaching of anatomy should be so directed as to familiarise the student with the relations of the internal organs in such a way that he may appreciate the significance of physical signs and symptoms when they are brought to his notice by his clinical teachers. This correlation of subjects can only be attained by a free and frank cooperation between teachers who keep before their minds that the main aim in their work is the fitting of the student for his life's work as a well-educated practitioner.

With regard to the final subjects of the curriculum the report takes the view strongly that there can be no efficient teaching of clinical medicine or surgery save to comparatively small classes, indicating that the opposite condition rules in Edinburgh. This is evidently the explanation of the suggestion that the four ordinary physicians to the infirmary should have the status of University lecturers or professors, with a common fee fund, and with the students equally distributed between them and the three University clinical professors. A working scheme on these lines seems to us easy of adjustment if the University will adopt a forward policy, and we trust she will do so. It is not to the true interest of medical teaching anywhere that a great teaching school like Edinburgh with its high traditions should drop out of the front rank from want of elasticity or from failure to adapt itself to new conditions and new requirements. We do not think that the most critical would formulate such an accusation exactly, but medical education is passing through an anxious stage, rivalries are many, and even the most honoured institutions are finding that they cannot progress on prestige.

The Structure of Isolation Hospitals and Sanatoriums.

ALTHOUGH experience of the value of both fever hospitals and sanatoriums for pulmonary tuberculosis has brought them down to a materially lower level as preventive and curative agencies than they occupied in the eyes of those who first advocated their establishment, the fact remains that both institutions are of very great utility and are certain to be provided, wherever the funds are to come from, in an increasing degree in the future. Neither alone will "stamp

out," as it is called, any of the diseases for which they are intended, but each will continue to serve a highly useful purpose and, employed in conjunction with many other measures and agencies, should have the effect in the case of isolation hospitals of limiting the spread of infectious diseases and enabling the members of invaded houses to return to work of to school, and, in the case of sanatoriums, of helping many with a tuberculous lung in its early stages on to the high road which leads to recovery, as well as teaching the patients how to prolong their lives hereafter and to be of minimum danger to their fellows. But in addition to these very solid arguments is the fact that the public, having once tasted the convenience and comfort of these institutions, will continue to demand their provision, and he would be a brave man who, because neither institution has quite come up to expectation, urged that existing structures should be done away with and no more erected. But it cannot, however, be denied that much more money has in the past been expended upon some of these hospitals and sanatoriums than need have been the case, and, this being so, such excess expenditure must be regarded in one way as wasteful in that it might have been devoted to some other branches of preventive medicine which might have been of greater value.

This excessive cost of fever hospitals has been brought about partly by the architects and partly by medical men, and it has been due in no small degree to the circumstance that the use of what are known as permanent-i.e., brick or stone-edifices has been regarded in the past as essential. But the improvements made in what are called "temporary" structures during recent years, and the durability and comfort of such buildings, are raising questions in the minds of many thoughtful administrators as to whether these temporary edifices, if thoroughly well constructed, may not, at least in many instances, serve quite as useful a purpose as the more costly permanent edifices. With reference to the provision for the infectious fevers Dr. J. C. McVail contributes to a recent issue of The Medical Officer 1 an instructive paper upon the cost and value of wood and iron isolation hospitals. Dr. MCVAIL circularised the county medical officers of Scotland on the subject, asking their experience and conclusions as regards the durability, cost, efficiency, and comfort of these buildings, and as to their suitability for phthisis and small-pox. It was found that there was considerable discrepancy of opinion as to the value of these "temporary" buildings, although practically all the replies were in favour of their suitability for the purpose of patients suffering from pulmonary tuberculosis, and it is of importance to have elicited unanimity even on this point. Some medical officers of health regard the trouble as to the repair of these temporary edifices as a distinct drawback to them, while others have found it difficult to maintain an equable temperature in them, but as to this latter point it must be remembered that the hospitals referred to were situated in rather colder climates than are generally experienced in England. But, on the whole, the county medical officers of Scotland have more to say in favour of these buildings than was, perhaps, to have been expected. Dr. McVAIL himself draws attention to a very important

point in the construction of these temporary buildings, and that is the need for the use of thoroughly seasoned wood. There is no doubt that many of the obvious drawbacks to these buildings are due in large part to defective construction, and if this be guarded against they are likely to serve very useful purposes for the acute infectious diseases. Unfortunately, some rather serious catastrophes have befallen some of these badly constructed "temporary" buildings, and there are several instances on record in which structures of this description have been completely wrecked during a high storm of wind, the patients having been carried out in blankets and placed under a hedge or otherwise disposed of. But the fact remains that there are many of these temporary buildings in different parts of England which are serving with satisfaction considerable populations, who but for these buildings would be without any isolation accommodation whatever. It has also to be remembered that not improbably in the near future the open-air method of treatment will be adopted in growing measure in connexion with isolation hospitals, and already at Nottingham Dr. PHILIP BOODBYER is treating cases of enteric fever and certain other diseases in this fashion. It is clear that if this practice becomes general the need for extensive isolation blocks of stone or brick ceases to exist.

As to sanatoriums for consumption, an inspection of the illustrations contained in Dr. H. T. BULSTRODE'S report to the Local Government Board upon these institutions will suffice to show that already a considerable proportion of the public institutions in this country are composed of materials to which the term "temporary" would be used, and there appears to be no evidence whatever to lead to the conclusion that the patients treated in the temporary structures fare less favourably than those housed in expensive palaces upon which several hundred pounds per bed have been expended; in fact, it is believed by many who have had experience of sanatoriums that those patients who are almost entirely in the open air fare better than those in the wards, and Dr. F. W. BURTON-FANNING at his sanatorium at Kelling has, we believe, found that patients whose temperature while kept in the wards was persistently elevated have had a normal temperature after a short rest in an open shelter. In all these circumstances it seems regrettable that the high cost of many modern sanatoriums is allowed to stand in the way of the provision of cheaper structures by leading the public to believe that the tuberculous sick can only be provided for in buildings which must cost at least £400 to £500 per bed. We are afraid that this belief has something to do with the small number of institutions erected recently.

Cholera in Europe in 1909.

It is a somewhat remarkable circumstance that the public mind in this country seems so little disturbed nowadays by the appearance of cholera in Europe, and that even the landing of an occasional shipborne case at one of our ports gives rise to no alarm. Our readers are doubtless aware that it was not ever thus, and that in days not so long distant the British ratepayer had as much reason for anxiety as many of his continental contemporaries. Indeed, our forefathers would have read with fear and anxiety even such a

communication as we publish this week from the British Delegate on the Constantinople Board of Health, giving an account of the spread of cholera in Europe in 1909. It appears from this report that cholera has been epidemic in European Russia during each of the last three years, and that the outbreak in 1909 was of considerable dimensions. From Russia cholera was conveyed by rail across the German frontier into East Prussia, as also down the River Memel into the same province. Owing to the excellent measures in force in Germany the disease in no case spread after i had been detected. From St. Petersburg and from certain Baltic ports cholera was carried on board ships to various European countries; but, as in Germany, the measures applied at Swedish, Norwegian, Danish, and English ports prevented any spread from the imported cases. In Holland, however, a sharp outbreak of cholera occurred at Rotterdam in the autumn, the infection having been carried there from Russia on shipboard; scattered cases owing their origin to Rotterdam were also observed along some of the Dutch waterways; and just across the Belgium frontier two groups of cases were also notified. This is practically all the cholera that occurred in Europe during 1909. With the exception of Russia, which is notoriously lagging behind in sanitary matters, particularly in neglecting protection of its water-supplies, none of the other European nations found much difficulty in dealing with imported cholera. It is well to bear in mind that the methods now employed by the most enlightened nations are those for which England has striven for many years and which she has endeavoured to induce successive international congresses to accept. For a long time the other Powers rejected these methods as being inadequate, and it was contended that only a seagirt land like Britain could run the risk of employing them. With the advance of knowledge and accumulation of experience continental opinion has come round to England's way of dealing with cholera.

This method imposes no restrictions upon intercourse between one community and another-town and town, nation and nation. England is content with providing for the care of persons actually sick and with obtaining the destruction of whatever may be harmful in the discharges from the cholera cases; and for the rest each community (under European conditions) can, if it pleases, render cholera harmless for itself by the adoption of practices which are profitable against other diseases as well as cholera. In land and sea traffic England has advocated the dispensing with those detentions known as quarantines, for they have been found in practice "to result rather in hazardous concealments and evasions than in any effectual exclusion of cholera." Thus it will be seen that England has depended in the first instance on general sanitary improvements as the basis of cholera prevention, and specially the safeguarding of public water-supplies. Further, to our port sanitary authorities has been entrusted the important duty of arresting actual or suspected cases of cholera on their arrival from infected countries. How well the officers of these port authorities have done their duty the records of this country in late years will testify. Placing implicit confidence in the authorities, the ratepayer, though he grumbles sometimes at the cost, sleeps in his bed in peace, notwithstanding that

cholera may be spreading on the continent. This system has not been evolved without a great struggle. A little over 50 years ago CHARLES KINGSLEY raised his powerful voice in protest against the apathy of the British Parliament respecting sanitary reform when cholera was knocking at the gate. We may be pardoned if we give here a quotation from an article published in 1858 in Frazer's Magazine by him: "The cholera, as was to be expected, has reappeared in England again; and England, as was to be expected, has taken no sufficient steps towards meeting it; so that if, as seems too probable, the disease should spread next summer, we may count with tolerable certainty upon a loss of some 10,000 lives. That 10,000 or 1000 innocent people should die, of whom most, if not all, might be saved alive, would seem at first sight a matter serious enough for the attention of 'philanthropists.' Those who abhor the practice of hanging one man would, one fancies, abhor equally that of poisoning many; and would protest as earnestly against the painful capital punishment of diarrhœa as against the painless one of hempen rope. Those who demand mercy for the Sepoy and immunity for the Coolie women of Delhi, unsexed by their brutal and shameless cruelty, would, one fancies, demand mercy also for the British workman and immunity for his wife and family. It is therefore somewhat startling to find that the British nation reserves to itself, though it forbids to its armies, the right of putting to death men, women, and children." That cholera in the past has killed many victims in England cannot be denied. As examples we may mention that in 1848 over 53,000 persons died from the disease in this country; and as late as 1866 14,378 deaths were referred to cholera in England, of which 5596 occurred in London. In the same year in Scotland 1170 cholera deaths were registered, and in Ireland 2501, of which 1459 occurred in Dublin. It has been, unfortunately, the custom for English Governments, in the past at least, to regard the advice of their medical experts with some distrust. Sanitary reformers have been regarded as dreamers, theorists, enthusiasts, unpractical men, faddists, to follow whose advice would cost the nation money. This view is not unknown in the present day, but the cost of sanitary works and the cost of sanitary administration in this country have more than justified themselves, not only in respect of cholera, but as regards other preventable diseases. The pioneers in this good work did not live to see the fruit of their labours, but they died in faith, as all good and true men die, "not having received the promises," but their works live after them.

Having attained this power over cholera, England cannot afford to relax her efforts. Pandemics of cholera arising in India sweep from time to time across Asia from east to west, and reaching the borders of Europe follow the usual route and penetrate into the interior of Russia by way of Astrachan and the mouth of the Volga. From Russia, whose neglected sanitary condition must be regarded as a menace to the health of Europe, the infection, as we have seen, is liable to be carried by rail, by river, or by sea to other western countries. It is, therefore, necessary to maintain a high standard of sanitation in England through constant and systematic inspection of our riparian and inland districts; we must maintain our line of sentries at our ports

to arrest the infected traveller as soon as he arrives and isolate him before he can do mischief to others. Our success depends greatly on the ability and efficiency of our medical officers of health, especially at our ports, whose work we think has hardly received that acknowledgment which it undoubtedly deserves. We have hardly left ourselves space to point out that painful experiments on human life upon a large scale have been needed to convince some Governments as to the soundness of the advice submitted by their medical advisers. The Broad-street pump disaster had its uses, as also had Hamburg's bitter experience in 1892. Such lessons have been repeated time after time in Russia, and more especially in St. Petersburg, but so far without definite result. Some allowance has, however, to be made owing to the present disturbed internal condition of that country. We trust that when these political clouds have passed away sanitary reform will be given the first importance, so that the dangers which from year to year threaten Europe from Russia may be speedily removed.

Annotations.

"Ne quid nimis."

THE BEIT MEMORIAL FELLOWSHIPS FOR MEDICAL RESEARCH.

WE publish in another column the details of the magnificent donation to science made by Mr. Otto Beit in memory of his brother, the late Alfred Beit. This donation is an event the importance of which in regard to those who are doing medical research work in the metropolis can hardly be over-estimated. We heartly thank Mr. Beit for his openhandedness, while the names of the trustees and of the advisory board form a full guarantee that the Fund will be wisely administered. The influence of Mr. Beit's act on medical education in London will be very great.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

THE Prince of Wales presided over a meeting of the General Council of King Edward's Hospital Fund for London which was held at Marlborough House on Dec. 13th for the purpose of awarding grants. The amount received by the Fund to Dec. 9th, after payment of expenses, is £133,977 5s. 4d., the League of Mercy again renewing its contribution of £19,000. The amount for distribution this year is £147,000 (with £3000 for convalescent homes), while the number of hospitals applying for grants is 103 as against 105 last year. The Prince of Wales moved the adoption of the various reports, which were carried unanimously. In reviewing the work of the year he referred to the loss which the Fund had sustained by the death of Mr. H. H. Clutton and of Mr. Marcus Gunn, who, as members of the Board of Visitors, had rendered invaluable service for many years. The largest donation received during the year was one of £4775, representing one half of the present available surplus of the Franco. British Exhibition. The amount available for distribution, namely, £150,000, represented the aim of the Fund and was therefore a landmark in its history. The distribution of such a large sum could not, however, be maintained without an effort. The income from investments had not yet reached £70,000, and it was necessary to rely upon annual subscriptions, donations, including the contributions from the League of Mercy, and legacies for the balance. The annual subscriptions had shown a diminution, but his

Royal Highness hoped that with the revival of trade would be a corresponding increase from this source. Referring to the work of the Distribution Committee, the Prince of Wales called attention to the amalgamation of the Orthopædic Hospitals and of the Hampstead and North-West London Hospitals, but regretted that the hope expressed last year of similar action on the part of the Throat, Nose, and Ear Hospitals had not yet been fulfilled. Considerable attention had been given to the consideration of proposals for the extension or improvement of hospital accommodation, and a subcommittee had been appointed to collect evidence with regard to the expenses of charity entertainments. That committee had arrived at the conclusion that there was no evidence of widespread extravagance or abuse, though there were certain dangers to be avoided. The proceedings terminated with a vote of thanks to His Royal Highness.

OLIVER GOLDSMITH.

On Nov. 29th Sir James Crichton-Browne delivered by invitation an address before the Society of Authors upon Oliver Goldsmith. He told his audience that his presence there was due to the fact that the secretary of the society had informed him that he and Dr. Goldsmith were born on the same day-namely, Nov. 29th-and hence the society considered it fitting that Sir James Crichton-Browne should be asked to speak upon Goldsmith. When, however, our gifted medical orator applied to the Dictionary of National Biography he found that Goldsmith had been born on Nov. 10th. The mistake obviously arose from the date being given on the memorial tablet in Westminster Abbey as Nov. 29th, and for this error no less a person than Johnson is responsible. 10th, however, was the date, and we should like to think that the actual time was just when the 10th was passing into the 11th, for that is St. Martin's Day, and if ever there was a follower of the saint who while yet a pagan divided his one cloak with the beggar it was Goldsmith. Sir James Crichton-Browne gave his hearers an account of Goldsmith's life, that shiftless, happy-go-lucky life, in which the darkness of debt, duns, bailiffs, and starvation was lightened by that "happy knack of hoping" which he claimed for himself and which he assuredly possessed. Though living in the eighteenth century Goldsmith was a throw-back to the wandering scholar of the Middle Ages. He studied medicine more or less at Edinburgh, when his uncle, Mr. Contarine, suggested that he should finish his studies at Leyden. He agreed; but being arrested for a debt not his own, but incurred by his having been surety for a friend, he embarked for Bordeaux. The ship had to put in to Newcastle, and there Goldsmith was arrested as being concerned in a plot to enlist Scotsmen for the French army. He was imprisoned, and on his release found that the ship had sailed. She was wrecked at the mouth of the Garonne and every soul on board was drowned. Goldsmith, however, had found a ship starting for Rotterdam, and sailing in her he reached that port after a nine days' voyage, whence he travelled to Levden. There he studied medicine and anatomy under Albinus, gambled away his substance, and was reduced to poverty. Being provided with funds by the generosity of Mr. Ellis, clerk of the Irish House of Commons, he set out for a continental tour. Characteristically, however, he saw some magnificent tulips, and remembering how fond Mr. Contarine was of flowers he spent all his money in bulbs and sent them to his uncle. Again penniless, he started to walk, and his account of his travels reminds the reader of nothing so much as the wanderings of those mediæval scholars whose songs are enshrined in the Carmina Burana. He had one new shirt and a German flute. He could speak French, a little Italian.

and a certain amount of Latin. He walked all day, and as evening drew on he played Irish airs on his flute which won him a night's lodging from the peasantry. He occasionally put up at a religious house, where it was still the custom that on certain days any wandering scholar who could maintain a thesis with ability would be rewarded with a little money, a dinner, and a bed. "Thus," he says, "I fought my way from convent to convent, walked from city to city, examined mankind more nearly, and, if I may so express it, saw both sides of the picture." He eventually arrived at Padua, in which University he may have taken his degree, although, on the other hand, the credit of so celebrated a graduate may be claimed by Louvain. He returned to England in 1756, as usual penniless. For a further account of his struggles, his debts, his successes, and his charities, all ably set forth in Sir James Crichton-Browne's address, we have not the space. That delightful comedy, She Stoops to Conquer, was first acted on March 15th, 1773. Walpole allows that it "succeeded prodigiously," and, he adds, "makes you laugh very much"; yet "it is a very wretched comedy." He died in 1774 from what Walpole calls a "purple fever." Sir James Crichton-Browne considers that probably the cause of death was chronic nephritis and uramia, possibly assisted by James' powders, which despite the entreaties of his medical man Goldsmith insisted on taking. So ended at the early age of 46 years one of the most attractive characters in literature. Johnson loved, admired, and helped him, and as to his writings, they are the treasures of all who read them. Well did Sir James Crichton-Browne say of the poems that they "seem to have the sweet scent of Surrey lavender, delicate and refreshing amid the pungent surprises and meretricious suggestions of modern perfumery of the coal tar series.' Walpole's dicta, "Goldsmith was an idiot, with once or twice a fit of parts," and "the poor soul had sometimes parts, but never common sense," are, we fear, true to a certain extent, but for happiness and the power of making other people happy compare his life to that of Swift, whose life was a chronic fit of parts. In more religions than one blessings are promised to the foolish, and if Goldsmith was foolish in a worldly sense he certainly gained the blessings.

THE MEDICAL DIRECTORY, 1910.

Messrs. J. and A. Churchill have issued their sixty-sixth annual Medical Directory 1 for London, the United Kingdom, and the Services, and we find it fuller of information than ever. On an early page is a tabulated numerical summary of the medical profession in each of the first 10 years of the present century. Whereas there were 36,354 qualified medical practitioners in 1901, there has been an annual increase ever since, the smallest increase of 289 having occurred in 1908-1909. The present issue shows an increase of 566 names over last year, and there are now 40,558 names of men and women holding British qualifications on the directory. Of these, 6427 reside in the London district, 17,568 in the English provinces, 1403 in Wales, 3947 in Scotland, 2723 in Ireland, 5188 abroad, whilst 3302 are in the services. An addition to the work is . a section devoted to British health resorts compiled by Mr. Norman Hay Forbes, F.R.C.S. Edin., in which brief descriptions are given of the topography, soil, and climate of 82 places in the British Isles, with a note of the diseases which may be treated advantageously at each. This section should be of use to many practitioners, for so far as we have tested the information it contains it is compiled with accuracy. We think it likely that the publishers will have difficulty in keeping it within its present limits. The list of

hospitals in the London district has undergone some revision and the summary of the principal laws affecting the medical profession, for which Mr. W. O. Hodges is now responsible, remains a valuable part of the work. The scope of the biographical details is unaltered.

THE DESTRUCTION OF RATS ON SHIPBOARD.

THE depredations of rats are notoriously a source of great loss to farmers, grain-merchants, and most of the traders concerned in the production and distribution of food-supplies, but no systematic destruction of rats on a large scale was attempted until microscopists discovered that they were liable to be infected with the bacillus of plague. Bacteriological research here came to the assistance of practical medicine in explaining both the causation of sporadic cases of plague in the human subject and the recurrence of epidemics which had apparently come to an end. Rats invariably abound in waterside warehouses and storage places, and as they come and go quite freely between wharves and the vessels lying alongside it immediately became evident that rats on board a vessel might convey plague from port to port, even across a great expanse of sea, without any cases among the crew. Hence the anxiety of sanitarians and epidemiologists for the extermination of rats on shipboard. It will be remembered that the Maritime Medicine section of the recent International Medical Congress discussed the means available. (THE LANCET, Sept. 18th, p. 875.) Many methods have been suggested for this purpose and a useful summary of them will be found in an article by Dr. Carl Prausnitz published in the July-October issue of the Journal of the Incorporated Society for the Destruction of Vermin. He first mentions the carrying of dogs, cats, and ferrets, although it is obvious that they would be of little service on board large vessels with holds full of cargo. Much more may be accomplished by the use of traps, several varieties of which are described and figured in the article; a well-known shipping company, Messrs. Elder Dempster and Co., pay a reward of 2d. for each rat caught on board their vessels, with the result that over 10,000 were destroyed during the year 1908; on an average between 20 and 30 rats were captured on each ship, with a maximum yield of 62 on one vessel. Poisons are also used for killing rats. One such poison is prepared from the pharmacopœial squill, whilst another consists of a powdery bait mixed with plaster-of-Paris, which proves fatal by absorbing moisture in the stomach of the animal and then hardening. The ordinary poisons used for rats-namely, phosphorus, arsenic, and strychnine -are hardly superior in their action to traps, while being at the same time liable to prove fatal to human beings, either by careless handling or through criminal intent. Phosphorous preparations are readily eaten by rats, especially if they are made up with plenty of fat, which, besides rendering them more palatable, also increases their toxicity. Such preparations are only reliable if smelling strongly of phosphorus, since under the oxidising influence of air they are gradually transformed into non-poisonous compounds, and therefore require to be renewed at short intervals. The smell given off by phosphorus by its warning effect also lessens the risk of danger to human life. It has been suggested that the luminosity of phosphorus in the dark attracts the rats. Poisonous gases are more efficacious for the destruction of rats on shipboard. Formerly it was the custom to take about one pound of sulphur and two pounds of charcoal per 1000 cubic feet of hold space: these were placed in braziers in the empty holds and allowed to burn with a slow flame. The hatches being battened down and the ventilators closed the flame extinguished itself as soon as sufficient charcoal

¹ The Medical Directory, 1910. London: J. and A. Churchill Pp. xxxvi. + 2071. Price 14s. net.

had been burnt to produce from 2 to 3 per cent. of carbonic acid in the air. After 10 hours the hatches were opened. This method is still used in some ports as a preventive measure before a vessel is loaded. Instead of the combustion of sulphur R. Pictet suggested the use of a mixture of compressed and liquefled sulphur dioxide and carbonic acid, contained in cylinders. This mixture, which he called "pictolin," is expensive and its use has not been generally adopted. Carbonic acid alone is not of much value, as rats can live in an atmosphere containing as much as 30 per cent., whilst lights cease to burn in 12.5 per cent. of carbonic acid. Carbon monoxide, on the other hand, is extremely fatal to rodents and is easily obtained at a low cost by burning coke in a limited supply of air. Dr. Prausnitz gives a full description of the apparatus designed by Dr. Nocht and Dr. Giemsa for this purpose and now in routine use in the port of Hamburg for all ships carrying plague-infected rats. Owing to the high penetrative power of the gas this method may be used in a fully laden ship, but there is a danger of persons losing their lives through accidentally inhaling the gas, and there is the further drawback that it does not destroy either insects or infection. Some of these disadvantages are obviated by the Clayton method, in which the gas employed is sulphur dioxide obtained by the combustion of roll sulphur. This method was invented by Mr. T. A. Clayton in conjunction with Dr. S. R. Olliphant, the President of the State Board of Health, Louisiana. It has been extensively employed both for purposes of fire extinction and for the destruction of all kinds of vermin. The complicated apparatus required for working the process is fully described by Dr. Prausnitz, as well as the "Marot" method and Dr. Wade's "auto-injector method," in both of which liquefied sulphur dioxide stored in drums is used. It has been proposed to destroy rats by laying down preparations containing a bacterial virus, which produces fatal septicæmia in a few days, and which might be propagated by healthy rats eating the dead ones. The objection to these preparations, at least for use on shipboard, is that the organisms in question belong to the paratyphoid or enteritis group, which give rise to the well-known occasional outbreaks of food poisoning or so-called "ptomaine" poisoning.

THE NATIONAL LEAGUE FOR PHYSICAL EDUCATION AND IMPROVEMENT.

THIS league, which held its fourth annual meeting at the Royal United Service Institute under the presidency of the Bishop of Ripon on Dec. 9th, exists to stimulate public interest in the physical improvement of the people, to coördinate and extend the work of agencies already established, and to start new organisations for the same end; to make known the legal sanitary powers already possessed by public authorities and to promote fresh legislation where necessary. The membership now is considerable and last year there was a substantial increase in subscriptions and donations, but the extension of the work obviously depends largely on continually growing financial support. working alliance between the league and the British Institute of Social Service has proved advantageous. The report alludes with regret to the resignation of Mr. F. J. Matheson. the joint secretary of the two organisations, and of Dr. May Thorne from the executive council, and records the election to that body of Mr. James Cantlie and Mr. F. E. Fremantle. The new work which is contemplated during the coming year includes the formation of a London Directory of Health Promoting Agencies, whether supported by the State or by voluntary aid, including particulars of gymnastic and drill classes and country holiday camps. An investiga-

in institutions, such as orphanages and special homes for defective children. Two joint committees of the league considered during the year the questions of physical education and of the milk-supply. The former unanimously adopted a series of recommendations that the physical education of school children should be compulsory in all schools subject to proper medical control, and that it should form part of the regular school curriculum and not be carried out in the hours of play, that thoroughly qualified gymnastic specialists should be attached to all secondary and intermediate schools, and that the Swedish system should form the basis of their instruction. The chief of the remaining sections of the report dealt with the branch reports of the league and with the sale of its publications. The amount of sales was a most satisfactory feature of the year's work; for instance, the sale of the leaflet on "How to Bring up a Baby "had increased from 8000 in the previous year to 38,000 in the year under review. At the meeting to which this report was presented the following resolutions were submitted and adopted. On the motion of Sir Hugh Beevor, seconded by Sir Lauder Brunton :-

This meeting deeply regrets that the legislation so imperatively required for the purpose of ensuring a pure milk-supply throughout the country has been deferred, and urges all Members of Parliament, irrespective of party, to unite in passing the requisite Bill into law as soon as possible in the course of the ensuing year.

On the motion of Sir William S. Church, seconded by Lord Meath: --

This meeting heartily welcomes the steps which have been taken to secure the national recognition of the importance of physical training and exercises under the most approved systems in schools of all grades, but is convinced that in order to provide a sufficient number of competent teachers in this department, it is essential that institutes for the training and certification of such teachers be established at the public expanse. public expense

And on the motion of Sir Richard Caton, seconded by Mr. Douglas Eyre :-

Whatever reforms eventually result from the reports of the Royal Commission on the Poor-law it is of urgent importance for the community to secure without delay adequate provision:

(a) For the treatment of the mentally defective separately and apart from all other persons requiring public assistance.

(b) For the boarding-out and training for rural industries, not only at home, but also in the colonies, of State children, and their disassociation as far as possible from institutional treatment and from the atmosphere of paucerism. atmosphere of pauperism.

Those who wish to express their sympathy with the league in a practical manner should communicate with the secretary, Denison House, Vauxhall Bridge-road, S.W.

BROCA'S CONVOLUTION AND MOTOR APHASIA.

AT a meeting of the Société Clinique de Médecine Mentale of Paris held on July 19th M. Marcel Briand and M. Brissot exhibited the brain of a case of motor aphasia of considerable interest, as the patient had been under observation for a number of years, and her clinical history had been published by Dejerine in 1898. A report of the communication will be found in the Revue de Psychiatrie for August. In 1896, at the age of 27 years, an apparently healthy young woman suddenly was seized with a stroke of paralysis and fell to the ground, remaining unconscious for ten hours. On recovering her senses she found herself to be hemiplegic on the right side and to have lost all power of speech. Before the ictus she had been able to speak four languages, French, German, Italian, and Spanish, but from that moment and afterwards she was unable to pronounce anything more than the two simple words, "oh non." A slight degree of word blindness, which was remarked, disappeared after a few months. The patient came under the observation of Professor Dejerine at the Salpêtrière, who considered the case very striking, the intelligence being of a high order and other cerebral functions being to all appearance intact. Her condition remained practically unchanged for ten years. tion is also being made into the medical inspection of children | Re-examination by M. Briand in May, 1908, showed the

existence of a spastic right hemiplegia, with exaggerated reflexes on that side. Spontaneous speech was nil, except for "oh non," used correctly and in its proper sense, however. The patient was unable to repeat words on request. With the letters of the alphabet before her she was able to spell out any word in any of her four languages, either spontaneously or to order. There was not the slightest trace of word deafness in any of these languages. Writing was perfectly performed with the left hand, spontaneously and to dictation, and copying was accurate. There was neither mind blindness nor mind deafness; no astereognosis or apraxia. There was no indication whatever of intellectual defect; the patient was well aware of her surroundings, of events in her life; memory, attention, and judgment were unimpaired. The case appeared to be one of pure motor aphasia, and in view of recent controversies unusually valuable. On May 15th, 1909, death occurred from renal causes and a necropsy was secured. The whole of the posterior end of the third left frontal convolution was completely destroyed by an old area of softening. In addition, on the right side another area of softening involved the inferior parietal convolution and the anterior and superior part of the angular gyrus. This cavity was roughly 2 centimetres in diameter and 2½ centimetres in depth, yet it had given rise to no symptoms of sensory aphasia. In view of the contention of some members of the Parisian school that Broca's convolution has nothing to do with the production of motor aphasia, a case of the above description ought to be noted by all who are interested in the subject.

THE KEEPING OF PIGS.

TASTE in the matter of pig-keeping varies a good deal in different parts of the world and, indeed, of the British Isles, and those who have wandered about the rural districts of Ireland must have felt that difficulties might arise in any very vigorous attempt to exact a very high standard in the matter. But even in Ireland common consent has accepted a different standard for urban as against purely rural districts. In England and Wales Section 47 of the Public Health Act, 1875, provides for a penalty against any person who in an urban district keeps any swine or pigsty in any dwelling-house, or so as to be a nuisance to any person, while Section 91 provides that any animal so kept as to be a nuisance or injurious to health is an offence. Although in England swine are very rarely, if ever, found actually kept in dwelling-houses, they are frequently, especially in some districts where the pork industry flourishes, kept under eminently undesirable conditions, and in this connexion a correspondent refers to an instance in which premises under a carpenter's workshop have been let and the tenant keeps pigs therein. It is not quite clear from our correspondent's communication whether the pigs are kept in a part of the premises in actual occupation of the new tenant, or whether the tenant simply uses all the premises for the purpose of pig-keeping. In any case the stench arising from the pigkeeping is so great that the carpenter cannot pursue his calling, and our correspondent asks whether the odour is injurious to health. It seems to us that the case is one, whether in an urban or rural district, in which the local medical officer of health and sanitary inspector ought to be able to afford the carpenter relief, and if by any chance the circumstances were such that the Public Health Act would not touch this case, possibly the carpenter might obtain redress at common law. In many places by-laws have been sanctioned relative to the minimum distance from dwellings at which pigs may be kept, and we believe that a distance of 100 feet has been allowed in some instances. The pig is the victim of what Dr. Ballard, in his classic writings on

offensive trades and the like, regards as a mistaken popular prejudice, and this prejudice militates against any trouble being taken to keep pigs in a cleanly state. In Ballard's view the pig is naturally a clean, not a dirty, animal, and his wallowing in the mire has for its object cutaneous cleansing, the mud standing to the pig in relation to soap to the human being, this mud when dry caking and falling off and carrying with it the hairs and cutaneous débris which irritate him. Similarly Ballard is found in defence of the good habits of the pig. The animal, according to him, does not habitually prefer disgusting food. In the wild state the pig does not eat garbage, but acorns, roots, and fallen fruits. It is said, too, that pigs which are provided with outdoor runs will never foul their beds, and that on very large pig runs, where pigs are provided with shelters for the night, a pig fouling the common bed is very severely handled by his fellows. There can certainly be no question that pigs may easily be kept in a cleanly state in properly constructed sties, and the more modern by-laws in reference to pig-keeping have relation more to the method of keeping the pigs than to the position of the sties. Experience shows that pigs kept in a thoroughly cleanly state thrive better than when in filth, and the nuisance relating to pig-keeping may by the exercise of moderate care be reduced to very small dimensions.

CHRONIC INFECTIVE ENDOCARDITIS.

BLOOD cultures made during life frequently serve to establish the nature of a febrile infection, and this is especially true in regard to infective endocarditis, both acute and chronic. That a peculiar form of infective endocarditis characterised by chronicity exists has been established by Professor W. Osler, and his account of ten cases published in the last issue of the Quarterly Journal of Medicine is an interesting contribution to the literature of the subject-Dr. Frank Billings of Chicago also gives details of 14 cases of chronic infective endocarditis, which he has himself observed, in an interesting paper in the Archives of Internal Medicine of Nov. 15th. He finds, as in the cases seen by Professor Osler, that the disease may be manifested for long periods by a slight feverish condition only. He is, however, of opinion that other symptoms are usually present but that they escape observation. Chills of varving severity, coming on at irregular intervals, and followed by fever and sweating, sometimes occur, and the cases may be mistaken for incipient tuberculosis, for colds, or for malaria. In his own series many of the cases showed a protracted course: in one patient the symptoms commenced two years before the condition was diagnosed, in another 14 months. A noteworthy feature of the condition is that in many instances the patients are ambulatory and do not become bedridden until some months have elapsed. Bacteriological investigation of the 14 cases showed the pneumococcus in 11 cases and a streptococcus in three. Dr. E. C. Rosenow, investigating these organisms, found that those obtained in the 11 patients with pneumococcemia had many of the morphological characters of streptococci, but cultural and animal experiments demonstrated that they were pneumococci. They all produced fine colonies on bloodagar plates. Hæmolysis did not occur. When grown in isolated colonies on the surface of blood-agar slants they all had a greater or lesser tendency to adhere tightly to the surface, and the more chronic the case and the later in the course of the disease the organism was isolated, the more marked was this tendency to adhere. The organism is Gram-positive; as a rule it is not surrounded by a capsule, and when grown in broth or litmus milk it forms diplococci with many very long conglomerate

chains. Cultures from all the patients showed a low degree of virulence towards animals, but endocarditis and pericarditis were obtained whether the organisms were administered subcutaneously or by intraperitoneal or intravenous injection. The three cases in which a streptococcus was reported were not examined as fully as the others, and Dr. Rosenow believes that had this been done they also would have been proved to be pneumococci. Dr. Billings suggests that in all cases where streptococcal forms are isolated from the blood these further investigations should be made, since they may possibly establish that the pneumococcus is the most frequent infective agent in endocarditis. With regard to the source of infection in his cases, Dr. Billings found that in one the condition followed pneumonia, in two tonsillitis had preceded it, and in two others alveolar abscess had occurred. In one case influenza was a possible factor in the genesis of the infection. An old heart lesion was present in seven of the cases, six of whom had suffered from rheumatic fever; the remaining one had had chorea. The valves involved in the 14 cases were as follows: aortic valve alone in 1; mitral alone in 6; pulmonary semilunars alone in 1; both aortic and mitral in 5; and mitral and tricuspid together in 1. With regard to treatment by vaccines, Dr. Billings found that inoculations of patients with large doses of their own dead pneumococci was always harmful and that small doses were devoid of benefit and even probably harmful.

THE PROPOSAL TO APPOINT A NEW MEDICAL OFFICER TO THE LONDON COUNTY COUNCIL.

As we announced last week, a subcommittee of the education committee of the London County Council has reported in favour of recommending the Council to appoint an additional assistant medical officer in the public health department, on account of the great amount of extra work entailed on that department by the systematic medical examination and treatment of school children. The subcommittee's report stated that when Dr. James Kerr was appointed as school medical officer by the London School Board his duties were to supervise the medical work generally, conduct correspondence, examine male candidates for employment, visit schools where outbreaks of infectious disease occurred, conduct inquiries, and give advice. It was possible to carry out these duties in 1902, but there had been a rapid expansion since, and it was now quite impossible for Dr. Kerr to exercise effective supervision without further assistance. The staff requiring superintendence numbered in 1902 - medical, 3; nursing, 1; clerical, 4; in 1909 the corresponding figures were 68, 54, and 28. Even these figures did not adequately represent the actual increase in the scope of the work. Various schemes had been developed since 1902 and were now in full working order, and in all departments the amount of detail was far greater. The Council now undertook the cleansing (heads, bodies, and clothes) of the children and examined their vision; it had established a laboratory for the bacteriological control of diphtheria; it exercised control of ringworm diagnosis; undertook inquiries into measles and scarlet fever, conditions of special senses, blindness, deafness, and aphasia; the medical examination of all scholarship candidates and the inspection of students in training colleges, pupil teachers, and the scholars of secondary and trade schools. The medical officer had to supervise all this work and many other matters too numerous to mention, and it was now almost impossible for him to master many recent developments, his whole time being occupied by the work already undertaken. The work of the care committees, the feeding of school children, questions of physical exercises, and the teaching of hygiene all required more thorough organisation, but the medical officer could not undertake it without

further assistance. The subcommittee thought the superintendence of the outside medical staff was almost one officer's work, and that the medical men and nurses should be seen at work not only in the statutory medical inspection but also in their duties in connexion with cleansing, special schools, and many other things. The relation in which the medical side of the Council's work had been brought recently with the sanitary work of the borough councils had necessitated a great amount of personal visiting and conferences with the medical officers of health of the various boroughs. The only full-time assistant medical officer was appointed in 1903, prior to the passing of the Education (Administrative Provisions) and Children Acts. The consideration of the report was postponed by the education committee, and even if it should reach the Council during the present session the past policy of that body does not give us much hope that the appointment will be made. There is no doubt that a strong case has been made out for it, but the creation of a new salary beginning at £500 a year and rising to £700 will probably give prolonged pause before

THE DEATH OF DR. LUDWIG MOND, F.R.S.

THE death of Dr. Ludwig Mond, F.R.S., on Dec. 11th last, removes a giant amongst the industrial chemists of the country. His chemical researches have met with enormous practical applications, none of which, however, can be compared for commercial importance with his discovery, which was the outcome of both his chemical and engineering knowledge, of the use of ammonia and carbonic acid gas in the conversion of common salt into carbonate of soda. He also observed the formation of those curious metallo-gases known as carbonyls, of which iron and nickel carbonyl are the most familiar examples. They are gaseous compounds of the metals with carbonic oxide, and the principle is now carried into effect in recovering nickel from its ore and for the purposes of purification. Dr. Ludwig Mond worked hard to encourage research, especially amongst young chemists with limited means at their disposal. He founded the Davy-Faraday Laboratory of the Royal Institution and having fitted it with all the appliances necessary for modern chemical research gave it an ample endowment. The investment has proved a fruitful one for chemical science, for some excellent and valuable original work has been done in the Davy-Faraday Laboratory. Dr. Ludwig Mond's name will go down to posterity as that of a man who did much to show the power and importance of research and who gave abundantly by various ways and means the opportunity to others of seeking out new facts. Can a man of science seek a better verdict!

RESEARCH DEFENCE SOCIETY.

THE meeting held at the Royal Pavilion, Brighton, on Dec. 13th, under the auspices of the Research Defence Society, was well attended, and the formation of the Brighton and Sussex branch was confirmed. The Earl of Cromer, as President of the society, presided, and he was supported by a thoroughly representative gathering of the medical profession in Brighton and Hove and other parts of Sussex. Lord Cromer, in opening the proceedings, alluded to the great loss the nation in general, and more especially those interested in medical research, had sustained by the death of Lord Selby, chairman of the Commission appointed a few years ago to inquire into the question of vivisection. Mr. Abel Ram, who was also a member of the Commission, had succeeded Lord Selby as chairman, and Lord Cromer remarked that he had been in communication with that gentleman, who had promised to do his utmost to secure the issue of the report early in the new year. Lord Cromer went on to say that humanity was on the side of those who devoted their time, their money, their unselfish labours, and sometimes their health to preserving and prolonging human life. Everybody who chose to go into the subject could satisfy himself beyond any manner of doubt as to the splendid results which had been achieved by bacteriological research. The most eminent men in the medical profession were practically agreed on the point, and, moreover, they were agreed on the fact that this knowledge would never have been reached had it not been for experiments on animals. He showed that in the proceedings of scientific research pain was very rarely inflicted, and that when it was inflicted it was amply justified by the results which had been obtained in preserving human life and in diminishing human suffering. Sir Arthur Conan Doyle, as president of the newly-formed branch, pointed out that of 88,000 experiments on animals conducted last year 85,000 were merely inoculations or injections, and he held that their opponents, who encouraged the abattoir and discouraged the laboratory, were in a most absurd and illogical position.

THE LATE SIR ALFRED JONES, K.C.M.G.

By the death of Sir Alfred Jones not English medicine only has lost a notable benefactor, for the world has been the gainer from the results achieved already by the Liverpool School of Tropical Medicine, of which he was chairman and virtually the founder, so large a share did he take in its endowment. He was one of the most striking personalities in British commerce, and had the qualities of enterprise and imagination which well entitled him to the name of merchant prince. In no manner was this better shown than in his practical interest in the advance of tropical medicine and in the equipment of expeditions to investigate its problems in partibus. Whereas the early merchant adventurers of England went forth prepared to win their fortunes by fire and sword, Sir Alfred Jones prepared the way for his modern argosies by subsidising men of science to investigate the causes of the diseases that play havoc with human life in tropical countries and the means by which they may be prevented, having the foresight to realise that by such means alone will the ruling nations be able to draw their full commercial tribute from the most fertile regions of the earth, whilst at the same time life will be made more secure for the subject races. In another application of science to trade Sir Alfred Jones showed his sagacity. By constructing special holds in his ships and making arrangements for the careful regulation of their temperature (which was charted four-hourly during the voyage) he proved that it was possible to transport bananas in excellent condition and in enormous quantities from the Canaries and the West Indies to this country, whereby not only his firm were the gainers but also the many poor people to whom a wholesome and palatable fruit was made available at a low price. We have said enough to show that commerce and medicine unite in real regret for the unexpected death of Sir Alfred Jones, a regret felt nowhere more sincerely than in his own city of Liverpool.

A FURTHER NOTE ON ENTERICIN.

WE have received a further communication from Mr. John Maberly of Woodstock, Cape Colony, on the subject of entericin, about which an annotation was published in THE LANCET of Nov. 6th. He states that the plant Monsonia biflora, from which he has obtained this substance, belongs to the natural order Geraniaceæ, and that it grows scattered over the high veldts of South Africa. An allied species, the Monsonia ovata, grows along the coast belt,

especially of the eastern side. He was unable to separate any alkaloid or glucoside, and in his endeavours to separate the active principles of the plant he obtained two sets of bodies-first, bodies of "indefinite chemical composition," to which he applied the name of "entericin," and a second group with astringent properties, to which he attributes the constipating effect produced by the tincture in some cases. In summing up his conclusions he states that the tincture has a distinct curative action on the ulcerative processes in the intestine at any stage of enteric fever and that when given after about the seventeenth or eighteenth day it has the power of cutting short the fever as well. He believes that the mixture of substances to which he has applied the name of entericin, produces similar actions to those of the tincture, but probably with a smaller constipating effect. He does not think that either the tincture or entericin produces any effect in cutting short the course of the fever when administered between the seventh and seventeenth days of the disease, although he is of opinion that if they be given before the development of Widal's reaction they may do so. Between the seventh and seventeenth days they may in some cases produce abdominal pain, and blood in the motions, and Mr. Maberly therefore does not recommend the continuous administration of the drug within that period. He admits that the evidence he has is not sufficient to permit of any definite conclusions as to whether the tincture or any of its separate constituents is the more efficacious. It would seem possible that in Monsonia biflora we possess an agent which is worthy of more extended investigation and trial, both from the pharmaceutical and therapeutic aspects.

A SURVEY OF THE PRESENT POSITION OF CANCER RESEARCH.

AT a well-attended conversazione held at the Polyclinic on the evening of Dec. 10th the chief feature was a brief but extremely interesting demonstration by Dr. E. F. Bashford on some aspects of the investigations of the Imperial Cancer Research, illustrated by lantern slides chiefly representing mice affected with experimental cancer of various organs. Having illustrated the similarities of the disease in uncivilised races of mankind and in animals, Dr. Bashford exhibited slides showing the completeness with which the lesions of cancer could be reproduced experimentally. While the conveyance of cancer from one animal to another by implanting a few living cancer cells might appear at first to demonstrate the reason for the great frequency of the disease, he held that facts proved that cancer was very rarely if ever so transmitted naturally. Subjects of cancer, whether naturally arising or artificially induced, were not sources of danger to other animals. The phenomena of resistance to the inoculation of cancer were explained. A sarcoma of a cat or mouse inoculated into rats would not grow in them, nor did such "vaccinations" protect the rats against subsequent inoculation of a rat sarcoma. Protection, on the other hand, could be induced by the "vaccination" of tumours as well as of the normal tissues of the same species, and even by the "vaccination" of an individual's own tissues. Animals could cure themselves of their tumours. Under given circumstances even 100 per cent. of the inoculated animals did so, and then they were protected against later inoculation of the same tumour. Experiment had demonstrated that a natural cure for cancer did exist, and had already placed in the hands of investigators weapons for ferreting out the nature of its mechanism. Although Dr. Bashford said he would only guarantee at present to protect any animal against inoculation, the evidence that the continued growth of inoculated tumours had been modified, and even brought

to a standstill, was already strong. Nevertheless, this result was still too inconstantly and uncertainly attained for him to arouse hopes of replacing empirical remedies in the immediate future. Meantime there was no alternative to surgical treatment. All empirical modes of treatment had one weakness in common, they only attacked the primary growth; even surgery was largely helpless to deal with metastases. The natural cure for cancer, when found, would be subject to no such limitation. Its triumphs would, in all probability, be in the direction of preventing dissemination and metastases formation. The lecture was listened to attentively and received with much applause.

THE Nobel prize in medicine has been awarded to Professor Theodor Kocher, who has gained a world-wide reputation in connexion with the surgery of the thyroid gland. Professor Wilhelm Ostwald of Leipsic has gained the prize in chemistry, and the prize for physics has been divided between Mr. Marconi and Professor Karl Braun of Strassburg.

A TELEGRAM from the Governor of Mauritius to the Secretary of State for the Colonies states that 26 cases of plague, with 14 deaths, were reported during the week ending Dec. 9th.

THE seventy-first annual report of the Registrar-General of Births, Deaths, and Marriages in England and Wales has been issued this week.

THE first volume of the Army Medical Report for 1908 was published on Dec. 14th.

THE CARE OF POOR-LAW CHILDREN IN BRIGHTON. -For the first time the South-Eastern and Metropolitan Poor-law Conference held its sitting in Brighton last week. The delegates received a mayoral and hospitable welcome, and the Majority and Minority Reports of the Poor-law Commission were vigorously criticised. Discussion on the care of the children occupied the whole of one day's sitting, and the work being carried on at Warren Farm Schools, Brighton, where some 250 boys and girls are being maintained by the guardians, was warmly commended. In reply to a delegate, it was stated that 95 per cent. of the children trained at Warren Farm succeeded in life. Several delegates visited the school and also the Brighton workhouse.

Exhibition of Psychiatry.—The RUSSIAN approaching third Russian Congress of Psychiatry and Neurology in St. Petersburg will be made the occasion of an interesting exhibition. It will be divided into scientific and practical sections. The former will contain subsections dealing with anatomy and physiology, neuro-pathology, psychiatry, experimental psychology, and instruments and bibliography. Besides specimens representing normal and abnormal conditions of the central nervous system there will be shown types and skulls of various races of Russia, apparatus and instruments for the investigation of mental and nervous diseases, tables and charts of results, photographs of patients, The latter section will have subsections and so on. dealing with the nursing of the mentally afflicted, criminology, and medico-pedagogy. Comparative tables the numbers of mentally afflicted in each given district and the total number of them cared for in the hospitals of the community will be collected, as well as tables showing the increase in the annual number of cases of various forms of mental disorder, a graphic representation of the influence of the Russo-Japanese war and the revolutionary movement on the abrupt rise in recent years in the number of the mentally afflicted and many others. The exhibition is being organised by the committee of the congress, with the director of the Psycho-neurological Institute, N. M. Bechtereff, at its head. All information respecting the exhibition can be had of Dr. N. Ya. Smieloff, chief doctor of the St. Panteleimon Hospital at Udielnoi, St. Petersburg.

THE BEIT MEMORIAL FELLOWSHIPS FOR MEDICAL RESEARCH.

WE have to report a most valuable instance of welldirected munificence. The following letter was read to the Senate of the University of London at its meeting on Wednesday, Dec. 15th :-

49, Belgrave-square, S.W. London, 10th Dec., 1909.

MY LORDS AND GENTLEMEN, - It will be within your recollection that my brother, the late Mr. Alfred Beit, in his lifetime and by his will, provided a sum of together £50,000 for the purpose of creating and assisting the Fund of the then proposed "Institute of Medical Sciences."

The formation of this institute owing to a series of circumstances having become impossible, the treasurers of the Fund were directed by an order of the High Court to return all moneys received for this purpose to the donors, and in consequence such part of the above sum as had already been paid was returned to my late brother's executors and by

them paid over to me as his residuary legatee.

It has always been my earnest wish that these moneys in some way should again be devoted to a public purpose as nearly as possible identical with that which had been originally contemplated by my brother. After considerable deliberation with those who had advised him, a plan has been devised the details of which are embodied in the accompanying Deed of Foundation. To give this Fund such extent as to make it, as I sincerely hope, thoroughly useful, I have decided to increase the above mentioned sum to £215,000 so as to yield by investment in Trustees' stocks an annual income of about £7500. I desire to name this Fund "The Beit Memorial Fellowships for Medical Research.

From this title, and on a perusal of the Deed, you will see that the Fund is to be devoted entirely to the furthering of medical research work in all its branches. A sum of £250 a year for three years is to be granted with this object to any man or woman of European descent, graduate of any approved University within the British Empire, who is elected to a Fellowship.

The Fund is to be administered by a Board of Trustees, who in their turn will be assisted by an Advisory Board of medical men. The names of those who have most kindly consented to act appear in the Deed, and I take this opportunity of expressing to both the Trustees and the members of the Advisory Board my sincere gratitude to them for undertaking the duties imposed upon them.

It is my most anxious wish to make this Fund a lasting memorial to my late brother, and I address myself, therefore, to your body, knowing as you do the deep interest Mr. Alfred Beit at all times took in the advancement of medicine and medical research. In view of the fact that such research is to be conducted almost entirely in institutions allied to the University, I venture to ask you to allow me to have the benefit of the advice of your Principal for the time being as one of the Trustees.

I feel convinced that the Trustees as well as the Advisory Board will at all times give every consideration to any recommendation your body may be good enough to pub before them.—I have the honour to be.

> My Lords and Gentlemen, Your most obedient Servant,

Отто Веіт. To the Senate of the University of London.

Mr. Beit's letter is so clear that no words are needed from: us to explain either the scope or the significance of his magnificent generosity. Those who remember the whole story of the proposed "Institute of Medical Sciences" will heartily rejoice that the University of London and University Colleges and Institutes in London, the medical schools and hospitals of London, and the important Imperial and national services which have their home in London have been made the recipient of such a princely endowment. It is hardly necessary to add that when this letter was read to the Senate on Dec. 15th the offer was accepted in terms of the deepest gratitude.

The names of the first trustees are as follows:-The Right Honourable Viscount MILNER, G.C.B., G.C.M.G.; the Right Honourable Lord CURZON OF KEDLESTON, G.C.S.I., G.C.I.E.; the Right Honourable R. B. HALDANE, K.C., M.P.; the

Principal of the University of London (ex-officio) H. A. MIERS, D.Sc., F.R S.; OTTO BEIT; JAMES KINGSTON FOWLER, M.A., M.D., D.Sc. (Hon.); BOURCHIER F. HAWKSLEY.

The Advisory Board is as follows:—Sir T. CLIFFORD ALLBUTT, K.C.B., M.D., F.R.S., Regius Professor of Physic, University of Cambridge; J. Rose Bradford, M.D., D.Sc., F.R.S., Professor of Medicine, University College Hospital Medical School, Secretary of the Royal Society; JAMES KINGSTON FOWLER, M.A., M.D., D.Sc. (Hon.), Senior Physician to the Middlesex Hospital, late Dean of the Faculty of Medicine, University of London; C. J. MARTIN, M.B., F.R.S., Director of the Lister Institute of Preventive Medicine; WILLIAM OSLER, M.D., F.R.S., Regius Professor of Medicine, University of Oxford; E. H. STARLING, M.D., F.R.S., Professor of Physiology, University College, London, University of London.

The temporary office of the scheme is Seymour House, 17, Waterloo-place, Pall Mall, S.W., but all correspondence of candidates for Fellowships and of Fellows should be addressed to the Honorary Secretary, Beit Memorial Fellowships for Medical Research, 35, Clarges-street, Piccadilly, W.

INFORMATION ABOUT THE FELLOWSHIPS.

The Fellowships are open to any person of European descent by both parents, without restriction as to nationality, who at the date of election has taken a degree in any Faculty in any University in the British Empire approved by the trustees, or who, if a female, has passed an examination which would have entitled her, if a male, to take any such degree.

In exceptional cases the trustees may, on the recommendation of the Advisory Board, accept the possession by a Fellow at the date of election of a medical diploma registrable in the United Kingdom as a qualification for a Fellowship in lieu of a degree.

There are no restrictions as to age, and no person is disqualified on account of his or her religious or medical

Ten Fellowships of the annual value of £250 are awarded annually, or such larger or smaller number as the trustees may determine. No canvassing is allowed, and testimonials need not be sent with the applications.

The first election of Fellows will be made on or about March 1st, 1910. The notice of this election will be given on or about Dec. 18th, 1909 (see advertisement columns of THE LANCET, p. 62). Applications must be received on or before Jan. 17th, 1910.

The usual tenure of a Fellowship is for three years, subject to determination by the trustees at the end of the first or second year, if in their judgment the work of the Fellow during the year does not justify the r-tention of the Fellowship. In exceptional cases the Advisory Board may recommend the extension of the Fellowship for a further period of one year—i.e., four years in all—but no longer. A report must accompany any such recommendation giving the special reasons for the extension. The trustees may in their discretion, for what they may consider grave cause, suspend for such time as they may think fit or remove any Fellow from his Fellowship, and from that date his emoluments cease.

The following are the recognised places of research, and Fellows may carry on research only at the place authorised by the trustees.

- A. University and University Colleges and Institutes.
- 1. The Physiological Laboratory of the University of London, South Kensington.
- 2. The Institute of Physiology, University College, London, University of London.
- 3. The Laboratories of the Departments of Chemisty, Biology, Physics, Anatomy, Pharmacology and Hygiene, University College, London, University of London.
- 4. The Laboratories of the Departments of Chemistry, Biology, Physics, Anatomy, Physiology, Pharmacology, and Hygiene, King's College, London, University of London.
 - 5. The Brown Institution, University of London.

B. Imperial and National Services.

- 1. The Laboratories of the Royal Naval Medical Service, Haslar Hospital.
- 2. The Laboratories of the Royal Army Medical College, Millbank, S.W.

- 3. The Lister Institute of Preventive Medicine.
- 4. The Laboratories of the Imperial Cancer Research Fund.
- 5. The Cancer Research Laboratories of the Middlesex Hospital.
- 6. The Laboratories of the Royal Commission on Tuber-culosis.
- 7. The Laboratory of the London County Asylum, Claybury, Woodford Bridge, Essex.
- 8. The London School of Tropical Medicine, Victoria and Albert Docks, S.E.
- 9. The Liverpool School of Tropical Medicine.
- 10. The Laboratories of the Royal Institute of Public Health, 37, Russell-square, W.C.
- 11. The Laboratory of King Edward VII.'s Sanatorium, Midhurst, Sussex.
- C. Medical Schools and Colleges and the Hospitals connected with them in all the Departments of their Work.

Such hospitals and medical schools as are schools of the University of London.

D. Such other Hospitals, Colleges, Medical Schools, including Schools of Tropical Medicine, Laboratories, or other places as may be approved by the Trustees after receiving a report from the Advisory Board.

Fellows are required to devote the whole of their time to their authorised research, and publication of such research must bear upon the title page the words "Beit Memorial Research Fellow."

EPSOM COLLEGE: THE ANNUAL DINNER OF THE EPSOMIAN CLUB.—The annual dinner of the Epsomian Club was held on Thursday, Dec. 9th, at the Trocadéro Restaurant, Mr. Percival Turner being in the chair. There was a good assembly, among those present being Dr. R. H. Whitcombe, the Suffragan Bishop of Colchester, Sir Henry Morris, the treasurer of the College; Mr. J. B. Lamb, the secretary of the College; Mr. Frank Ree, general manager of the London and North-Western Railway; Dr. F. de Havilland Hall, Dr. W. Essex Wynter, Dr. H. Campbell Thomson, Dr. S. Squire Sprigge, Editor of THE LANCET; and Mr. Edred M. Corner, secretary of the Epsomian Club. Mr. Percival Turner gave the toast of "Floreat Epsomia" and commenced an excellent speech by apologising for taking the chair in the unavoidable absence through illness of Surgeon-General A. M. Branfoot, I.M.S. He testified to the continually progressing success of the school, while he described at some length the splendid block of buildings recently erected by the munificence of the late Mrs. Markham Skerritt. the equipment for scientific education included in which he claimed to be equal to, if not superior to that possessed by any public school in the kingdom. The headmaster, the Rev. T. N. H. Smith-Pearse, in reply, gave some interesting details in proof of the present high state of efficiency which the school has reached. Sir Henry Morris proposed "The Health of the Visitors," coupling the toast with the names of the Bishop of Colchester and Dr. Sprigge. He spoke in generous appreciative terms of the interest which had always been taken by THE LANCET in the prosperity of Epsom College, and mentioned the very practical benevolence shown to the College by the Wakley family. The Bishop of Colchester made a witty reply, in which he alluded to the time when he himself had been a small boy at Epsom College and had taken ladies' parts in the Epsom play. Dr. Sprigge congratulated the College on having definitely taken its place among the public schools of England, and pointed out that the facilities for scientific education alluded to by Mr. Percival Turner would be much appreciated by those intending to join the medical profession. Mr. Frank Ree also responded to the toast and gave some humorous reminiscences of the days when he was a schoolboy. Mr. C. L. Smiles proposed the health of "The Chairman," who responded briefly. The speeches were interspersed with music, songs being given by Mr. W. A. Mackay, Mr. J. N. Eggar, and Mr. J. S. Cotman, while Mr. C. E. Stredwick, a visitor, repaid his hosts with some excellent flute solos. The last song on the programme was an original and topical ballad, entitled "The Roast Beef of Old Epsom." This was rendered with much spirit by the Rev. C. E. Elcum, the vicar of St. Agnes, Liverpool, its author, the chorus being joined in by the assembled company.

THE

STANDARDISATION OF DISINFECTANTS: CRITICISMS OF OUR COMMISSIONERS' REPORT.

WE publish in another place various letters which we have received upon the recent report of our Commissioners, and below is the comment of our Commissioners upon the criticisms in these letters, with references also to correspondence on the subject published in other journals.

THE CHEMICAL SECTION OF THE REPORT.

Let us commence by saying that it is incorrect that the report of THE LANCET Commission had its starting point in a paper read by Mr. M. Wynter Blyth at the Applied Chemical Congress held in London in May, and in a paper published by Constant Ponder and G. Sims Woodhead in the Journal of Pathology, vol. xiii., p. 152, July. That is not the case, for the work of our Commissioners was discussed early in February, and commenced in March.

It is properly pointed out by one critic that the baryta method may be liable to error arising from the incomplete extraction of the phenols, and has quoted experiments which appear to lend colour to that view. We did not, however, found our faith in the process on a single control, as he states—that is, in a mixture containing not phenoloids but carbolic acid—for we said (p. 1457): "It should be added also that in the case of one of the commercial preparations examined the kind and amount of the components used in its manufacture were known." As to the varying degrees of solubility of known." As to the varying degrees of solubility of different phenoloids it may be pointed out that baryta water was not used as the critic assumes. but 15 grammes of the hydrate in 100 cubic centimetres of boiling water, which is a quantity far in excess of that contained in an equal volume of baryta water. Further, it should be pointed out that in using baryta the decomposition of the soaps, &c., results in some caustic soda being formed in which, as he suggests, the phenoloids are probably more easily soluble. The method as regards both soap or resin emulsions and glue or gum emulsions is thus comparable. By first carefully emulsifying the disinfectant with water, by boiling it with a large excess of baryta under a reflux condenser, by washing the residue with warm baryta two or three times, taking care to rub down the mass with a stout glass rod, the extraction of practically all the phenoloid is ensured. Since receiving this criticism we made up the following mixture containing phenoloids and not carbolic acid:-

Phenoloids	 			31·24 p	er cent
Soaps and resin	 		• • • •	31.18	••
Water	 	•••		20.78	,,
Neutral oil	 • • • •	•••	•••	16:80	••
				100.00	

The resin proved to form with baryta a mass somewhat difficult to deal with, in spite of which the results of three determinations of the phenoloics were as follows: phenoloid, 30.62 per cent., 30.98 per cent., 30.30 per cent. The estimation of the other constituents gave soap (fatty acids, resin, and soda), 31 58 per cent.; water, 21.00 per cent.; neutral hydrocarbons (by difference), 16.79 per cent. We submit again that these results give a fair statement of the composition of the synthetic fluid, but certain precautions must be observed. In the absence of resin or in the presence of soap there is no difficulty about complete extraction. As regards the weighing of the phenoloids, the results were good when the evaporation of the last portion of the ether was allowed to take place over anhydrous calcium chloride. In this connexion it may be pointed out that Jeyes' Fluid (No. 2) gives by this method 5.13 per cent. of phenols, and this fluid is "guaranteed exempt from the provisions of the Poisons Act," which means that it is intended to meet the clause in that Act which allows carbolic preparations containing not more than 3 per cent. of carbolic acid to be sold without a label stating that the contents are poisonous. The analytical method, therefore, in this case extracted rather more phenols than might have been expected. The comparatively large proportion of hydrocarbons in this preparation do not appear, as is suggested, to enhance its

germicidal power, since the carbolic coefficient was only 0.75, the $\frac{P-B}{3}$ value being 1.0.

We have not attempted to offer any explanation of the differences given by the bromine value in terms of carbolic acid and the actual weight of phenoloid found, but it is certainly remarkable that a series of figures, call them arbitrary if we will, worked out in the way described should set out an order of germicidal efficiency determined by independent bacteriological experiment.

The ingenious criticisms (contained in the Medical Officer of Nov. 27th and Dec. 4th, 1909) might have been taken seriously if we could think for a moment that they were based on laboratory trial of the L.A.B. method. Practically all of the writer's points are met by the fact that the L.A.B. chemical method gave correct results with mixtures the composition of which was absolutely known. We have nothing to say about what the writer calls his acetone We have method, and we daresay it gives good results; but in the practice of the public health laboratory it is inconvenient and involves the use of considerable quantities of reagents. The suggestion to use acetone in the analyses of disinfectants originated in THE LANCET Laboratory, though the fact was not acknowledged, and we are glad that it has been found to be serviceable. Further laboratory experience will probably lead to more importance being attached than is the case now to the bromine value, the determination of which in THE LANCET experiments did not admit of the error (due to absorption of iodine by the bromo-phenoloid) which is crudely suggested. The articles in the Medical Officer illustrate once more the desirability of the subject of disinfectants being discussed by independent scientific authorities.

In a letter published in the British and Colonial Druggist of Dec. 10th, 1909, Messrs. Jeyes' Sanitary Compounds Company state that our Commissioners say that "the greater the percentage of phenoloids in a disinfectant the greater must be its germicidal activity." Our Commissioners did not say this. What they said was that "chemistry suggests the germicidal potentials of a disinfectant, and it is for bacteriology to tell us how far these potentials are realised under varying conditions," and that "when we come to compare the chemical behaviour of the various phenolic constituents of disinfectants with the bacteriological findings we shall see that under certain conditions the carbolic coefficients calculated upon the results of bacteriological experiment appears to be indicated by certain chemical factors." In a great many cases, however, the quantity of phenols definite bacteriological quality. Messrs. Jeyes' Fluid, for instance, showed by analysis 17 80 per cent. of phenols, and its carbolic acid coefficient (mean) was 1.7, the $\frac{P-B}{3}$ value being 2.1, while Jeyes' Fluid No. 2 was found to contain 5.13 per cent. of phenols and its carbolic acid coefficient was 0.75, the $\frac{P-B}{3}$ value being 1.0. It is difficult to suggest in the face of these results that there is no relationship whatever between the amount of phenol body present and the germicidal efficiency of the preparation.

THE BACTERIOLOGICAL SECTION OF THE REPORT.

Criticism of the work in the bacteriological section of this report has, we cannot but think, been answered in anticipation in our summary of conclusions, and were it not that we are anxious to give, and in return to obtain, as much information as possible, we should now feel almost satisfied in having been able to bring erstwhile antagonists into line even though they are against some of the minor conclusions of our report.

It may afford some satisfaction to those interested, to know that our work was undertaken partly in order to cut short, if possible, a discussion that was becoming somewhat acrimonious, carried on by certain of those interested in disinfectants of various brands, a discussion that seemed likely to be prolonged indefinitely unless, to the advantage of the public, the matter was taken in hand and settled point by point by impartial observers.

As we wish to eliminate as far as possible any personal element we will answer our critics as a body and not as individuals, and in addition to the letters printed in the

present number of THE LANCET we refer to articles by Mr. M. Wynter Blyth in the Medical Officer of Nov. 27th and Dec. 4th.

We will begin by saying that we think some of our statements have not been read with sufficient care. It is not realised, for example, how few are the unbiased data available on which to base a study of disinfectants acting on naked cultures, and we point out that this may be because the methods employed are somewhat difficult to apply and even when successful give comparatively meagre information. In these circumstances, as we have pointed out, there is some excuse for those interested in special disinfectants who read results comparatively favourable to those disinfectants when applying these methods.

Our report deals with what, after all, must be the first question to be settled—the relative power of disinfectants to kill a naked culture; and we show that fairly consistent results may be obtained by a modification of a method the principle of which, if properly applied, is thoroughly sound, within a strictly limited set of conditions. We published our results at this stage of our investigation because we know that for some time to come those who buy and sell disinfectants will fix the money value by the carbolic acid coefficient, and because we can put into the hands of those who have to give advice on this matter what we believe to be the truest means of obtaining the information on which they are expected to act.

We consider that the advantage of our modified Rideal-Walker test is that not only the same highly skilled worker, but moderately skilled and careful workers may obtain similar results time after time. A very casual study of one or two of the papers read at the recent International Congress of Applied Chemistry will bring out the importance of this. Our modifications are objected to on the score that they complicate the method and some of our critics speak of "elaborate machinery" and "vast numbers of tubes," and ask whether "complications of a simple process are of real advantage." Our reply is that we have not used elaborate machinery and have brought accuracy to places where it was lacking.

The records of the Chemical Congress offer evidence that others who have used the Rideal-Walker method have not always met with complete success. Each of our charts carries its own credentials. That our method is fairly simple and uncomplicated may be gathered from the fact that a medical man who has been in one of the Services for a long time, who has had no special training in bacteriology beyond a three months' course ten years ago, volunteered to help us in the continuation of our work and at his fifth experiment obtained a quite regular chart. have no doubt that other methods in the hands of a skilled worker, constantly in practice, may prove reliable, but at the above-mentioned Congress it was stated that three observers, all of them "skilled," obtained results that can scarcely be called satisfactory. In further confirmation of our contention that different observers, working with the Rideal-Walker method, do not agree in their results, we draw attention to the carefully compiled table given by Major C. E. P. Fowler in the Journal of the Royal Army Medical Corps, 1907, vol. ix., pp. 54-58. Major Fowler's own coefficient figures, taken as a whole, though usually somewhat higher than ours, certainly appear to confirm the accuracy of our comparative results. That such different results can be obtained is, we hold, evidence against the general reliability of any method. The Martin-Chick method is, no doubt, very accurate, and for the conduct of certain kinds of work is essential, but for it to be successfully carried out a very large amount of skilled assistance is required. For the purpose of obtaining such curves as we desired it would not be sufficiently comprehensive. One of our critics writes: "Moreover, the tubes do not show any improvement through using a spoon instead of a loop. To inoculate 12 tests in 2½ minutes with proper mixing must demand great skill whatever apparatus be used." Had we not used the spoons we might no doubt have made a similar statement and we do not quarrel with anyone for being a little incredulous on this point. We do object, however, to the ignoring in the first part of the statement the undeniable advantage of obtaining in one experiment so many additional data on which to calculate results; whilst as to the second part, we can only quote the old Scotch saying that "the proof o' the puddin's in the preein' o't."

It is objected that in using the second factor for our coefficient half an hour is too long a period during which to allow the disinfectant to act. May we point out in answer to this that with a complete carbolic acid curve the carbolic acid coefficient for any disinfectant may be calculated at any point from 2½ minutes to 30 minutes by those who do not approve of the "mean" coefficient we have provided.

approve of the "mean" coefficient we have provided.

In support of our contention that the bacillus coli communis has a "resistance" corresponding closely to that of bacillus typhosus, may we draw attention to Tables II. (one of our three typical Rideal-Walker charts) and X of our report, in which it will be seen that with Cyllin, taking that as an example, we obtained a carbolic acid coefficient of 8.7, by the Rideal-Walker method, for the bacillus typhosus, and of 8.8 by the method as modified. Moreover, if we take the 7½ minute and the 10 minute results obtained by our method and compare them with the figure obtained by the Rideal-Walker method, using the data of our carbolic acid table (Table III.) we obtain the coefficient for Cyllin of 8.75 as the mean between the 7½ and 10 minutes coefficients with B. coli communis.

In thus meeting this criticism we are not wishing to score a point," we are simply desirous of setting forth an alternative view. Again, one of the critics writes: "I have contended all along that these tests to be of any value must be done by a trained chemist and that many of the errors and disputes in the past have arisen through carelessness or want of skill on the part of the investigator." We should go beyond this and say that to obtain successful results by that test not only chemical training and great technical skill but some knowledge of bacteriological methods and problems are necessary. He continues: "It is, however, very astonishing that the Commissioners themselves admit the fact that they could only get three out of eleven consecutive tests; the conclusion is an obvious one, and it makes it possible for me to challenge their statements that no fluid on the market has a higher Rideal-Walker figure than 13. Apart from my own work there must be thousands of tests now recorded throughout the world showing that for some years Cyllin, and now other, manufactures have regularly been on the market with a Rideal-Walker figure much higher than that named." We would point out in all good humour that if the "obvious conclusion" referred to is that we admit a lack of technical skill in not obtaining a definite result there are only two alternatives-either THE LANCET Commissioners must be singularly incompetent not to be able to obtain better results after the considerable amount of practice they have had, or, the test demanding the technical skill, chemical and bacteriological knowledge, and general expert ability of what Mr. Bernard Shaw might call a "super it is not one to be utilised by the medical officer of health or one that can be of any great value to the average laboratory worker who cannot keep up continuous practice, and who has not the opportunity of calling in at a moment's notice the assistance of an expert. We anticipate that with our modification the method will be applied far more generally and by the worker of average skill. Our exact words are: "The bacteriological results are so consistent throughout that we have little hesitation in putting them forward as affording an accurate indication of the germicidal power of disinfectants we have tested. We are fully satisfied on this point although in our investigation we have not found such high coefficient figures as have been given by other observers. Neither with the Rideal-Walker method nor with the modifica-tion we have made use of have we under any conditions obtained (any) carbolic acid coefficient figure higher than 13." This surely can refer only to the disinfectants on which we are reporting and concerning which all data are given. It is because such higher figures have been given by the "many observers" that we feel justified in doubting the accuracy not only of these but of some other figures, and in laying such marked stress on this

Moreover, with regard to the statement that our coefficients as a whole are too low we may point out that one of our critics offers the following: "Broth is a more delicate test for the recovery of the organism than is bile salt medium. I have had no opportunity of using the spoons, but think that in some cases a quantity of disinfectant sufficient to inhibit growth in the MacConkey tube might be introduced." Surely, even casual consideration will show that if such be the case our coefficients are unduly high, since the lethal

dilutions used in our carbolic acid control appear to correspond closely with those generally made use of in Rideal-Walker tests.

Some play is made with the fact that there is a difference between certain coefficient figures published in the Journal of Pathology and those given in THE LANCET report. In both the instances quoted the figures vary in the same direction. In THE LANCET we refer to the fact that in our original calculations the control phenol was worked out as being unduly weak. Later this error was corrected after a series of special tests had been made. The whole of our series of disinfectants then showed a slightly higher coefficient figure.

We ask our critics to read carefully everything from "Table XIV." of THE LANCET Report to the last word of the column in which it appears. We rely on the figures included in that table as containing sufficient answer to any criticism hitherto offered on this point.

In the Journal of Pathology we were simply calling attention to our method and the disinfectants were unnamed. In THE LANCET the corrected coefficient figures are given. our earlier experiments we kept our carbolic acid dilutions and emulsions, as recommended for the Rideal-Walker method, 24 hours after we had prepared them before we tested them. Although we make the statement that we obtained certain results with carbolic acid kept in solution for 24 hours, we had realised that what is spoken of as a "fall" might be nothing more than an experimental error. In any case, the "24 hour phenol" appeared to have no advantages over freshly dissolved phenol and we say "apparently, also, the phenol loses very little of its bacteriological power, but we considered that this was sufficient to compel us to use freshly made solutions for each experiment." In a case of this kind where experimental error may come in, but where there might be something beyond such experimental error, we determined to get rid of those sources of error, at any rate, that were avoidable.

Some of the statements made and suggestions offered appear to us to assume an ex-parte form rather than one of genuine criticism of our work, and we feel that were we to attempt to answer them all we should be led into a loose and wordy controversy on which we have no intention of embarking.

We are accused of making our observations "upon old and superseded preparations." All the results published were obtained with samples bought on the open market just before the tests were made. It is at least regrettable that the stronger samples referred to were not universally distributed. Concerning one of the preparations it is stated that "its germicidal value is, I believe, considerably higher than that expressed in THE LANCET report." Naturally, full credit must be given for this belief, which, however, from the results of our own experiments, we feel justified in tooking upon as being not entirely unbiassed.

The germicidal factor must always remain the basis of these tests, and however great and prolonged the "revolt against the autocracy of the microbe" may be, some kind of a "revolt" will still have to be carried on so long as the microbe remains alive. Sanitas Disinfecting Fluid was originally included in our list because it was advertised and recommended in the directions on the bottle to be used as, among other things, an effective germicide. We made an obvious slip in Table XXIV., where Sanitas Disinfecting Fluid was classed as a coal-tar disinfectant forming a clear solution with water. This slip, which we much regret, we corrected at once, and omitted any reference to the fluid from our table of comparative prices. We agree that it is absolutely impossible to determine the relative values of various disinfectants by any one test, but we claim that anything that will give information on the subject of disinfection is called for in the public interest and in the service of municipal authorities.

We claim no "inside" knowledge of any of the disinfectants we have tested. We have approached the question entirely from the standpoint of outside observers who wish to obtain knowledge ultimately to be applied to practical disinfection. It is a matter of indifference to us which disinfectant gives the test results, but it is equally

a matter of importance that we should, so far as possible. accumulate facts. Where we have not been able to obtain these facts we have reserved our opinion.

We entered upon this investigation with an unbiassed mind, and we think we have succeeded in preserving that attitude. We cannot be blind to the tinge of acrimony that has characterised much of the inter-disinfectant controversy, and we wish to avoid anything of the kind in connexion with our present work. We have considered it necessary to answer our critics because we believe that each one is desirous of helping us to obtain definite facts bearing on a very important question. Having done so we intend to leave the discussion to others until we have more facts to communicate. Certain of the points that we raise in our report are receiving further attention, and as soon as we have any reliable data to communicate they shall be placed in the hands of those interested. In the meantime we shall welcome any assistance that may be placed at our disposal by those who have knowledge that we do not possess, knowledge which they may feel justified in communicating to, or anxious to place before, us.

THE FEEDING OF NECESSITOUS LONDON SCHOOL CHILDREN.

As reported in THE LANCET of Nov. 27th, p. 1640, the Education Committee of the London County Council has asked for a supplemental estimate of £25,000 to meet the cost of feeding necessitous school children during the period ending March 31st, 1910. The Finance Committee, however, reporting to the Council on Dec. 14th, advised that only £15,000 of the estimate should be sanctioned until the Council has fully considered the way in which the Provision of Meals Act is being administered in London. They were advised that from Oct. 1st, 1909, to March 31st, 1910, there would be provided 5,074,300 meals costing 1½d. per meal, or £31,714 plus £5286 for service. The total estimate for the year was £62,265. This, however, did not represent the whole cost of the provision of meals, for it included nothing in respect of establishment charges, whereas the organisation had thrown a very heavy burden upon the education department. The committee thought the Council should be informed of the total cost of administering the Education (Provision of Meals) Act, 1906, and they were obtaining the information. The tendency to provide free meals, especially out of the rates, was undoubtedly to induce an increasing number of parents to obtain free meals for their children, and it was of the utmost importance in the interests of the ratepayers that there should be careful discrimination between cases which were, and those which were not, necessitous. The committee had inquired into the existing arrangements for recovering the cost from parents. scheme approved by the Council was not yet fully in operation, but the school care committees were being formed. was therefore too early to form a definite opinion as to the effectiveness of the procedure decided upon. The total number of free meals supplied in 1908-09. whether out of rates or voluntary funds, was 4,546,771. The original estimate for the current financial year was 6,000,000, and this number was now increased to 7,702,506. No reason was given by the Education Committee for the enormous increase of 3,255,000, or 70 per cent., over last year's figures. appeared to point to the failure of the present procedure to effect the desired object of securing that only really necessitous children should be fed at the expense of the rates. Finance Committee had therefore asked the Education Committee to reconsider their methods and to give the Council full information as to the nature of the tests and safeguards upon which they proposed to rely for restricting the giving of meals to really necessitous children. It was obvious that unless great care and scrutiny were exercised the number of free meals would continue to grow, and it was difficult to see what the limit (other than the statutory one of a halfpenny rate) would be.

The amount included in the annual estimates as likely to be received from parents in repayment of the cost of food

was £1000, but for the six months to Oct. 31st, 1909, the sums actually recovered amounted to only £26. This was entirely unsatisfactory, and called for careful consideration. The Finance Committee criticised the terms of the circular letter sent to parents as soon as their children had been fed by the Council. The letter quoted the emphatic words of the Act that parents "shall" be charged with the cost of food when they can pay, and then, after giving particulars of the cost of meals, added, "These facts are told you in order that you may pay if you can." In the opinion of the committee the letter appeared to convey an impression in conflict with the Act. This procedure was not calculated to result in the recovery of the amount which the Act contemplated should be recovered, and it should be revised. They had pointed out on more than one occasion that the principle upon which the Education Committee should act in respect of the recovery from parents of the cost, not only of feeding but also of medical treatment, was that repayment should be the rule, exception being made only in cases where it was proved that the parents could not contribute. They had asked the Education Committee to strengthen their administration in this matter, and also to modify the circular letter. The sum of £15,000 would suffice until the middle of February, when they would submit a further report.

The report was received without discussion. On Dec. 15th the Education Committee decided to ask the London boards of guardians to make monetary allowances to the Council in respect of meals given to children whose parents are in receipt of out-relief, in order to avoid overlapping. It was pointed out that a similar difficulty will have to be met in respect of medical treatment.

Looking Back.

FROM

THE LANCET, SATURDAY, Dec. 17th, 1831.

THE CHOLERA IN THE NORTH OF ENGLAND.

At the moment of our going to press we have received a letter from a physician at Sunderland, on the subject of the disease prevailing in that town, under the name of "The Cholera,"—the Blue Cholera of India. as we have for some time designated the desolating pestilence which has commenced its scourges in the North of England.

* * * * * * * * * * (Excerpt of the letter mentioned above.)

Accompanied by Mr. Kennedy, the distinguished writer of the excellent book which has so deservedly elicited your praises, I this day went to visit a woman named Henry, who had been attacked with the disease in a severe form about twenty-four hours previously. We tracked our way through a dirty lane near the barracks, ascended a tottering escalier, and found ourselves in a small, though not uncomfortable, apartment. On the bed lay the expiring woman, apparently aged at least 70 years, and presenting a shape and attitude of death, which, although accustomed as I am to its most variegated shapes, I never saw paralleled in terror. But I close the curtain on this patient, and turn to a more instructive object. On the floor, before the fireplace, extended on a palliasse, covered with a solitary blanket, and surrounded by a group of female friends, lay a girl of slender make and juvenile height, but with the face of a superannuated hag. She uttered no moan, gave expression of no pain, but she languidly flung herself from side to side, and from the supine to the prone position. The colour of her countenance was that of lead—a silver blue, ghastly tint; her eyes were sunk deep into the sockets, as though they had been driven in an inch behind their natural position; her mouth was squared; her features flattened; her eyelids black; her fingers shrunk, bent, and inky in their hue. All pulse was gone at the wrist, and a tenacious sweat moistened her bosom. In short, Sir, that face and form I never can forget, were I to live beyond the period of man's natural She had vomited some whitish watery matter at few and distant intervals, and had had a few insignificant dejections of the same kind.

I appeal to Mr. Kell, the surgeon of the 82nd, to Dr. Reid Clanny, to Mr. Kennedy, to Dr. Morreis,

and to numerous others who have seen this case, to say whether I have not understated, rather than exaggerated, its features. And, secondly, I appeal to any practitioner in existence, whose mind is not warped by prejudice, and the expression of whose opinions is not restricted by former declarations, whether he has ever seen a case of our cholera corresponding to that description. Would to God I could bring the sceptics here, and show them the girl Henry! And if they can confound the exhaustion on the essential vomiting and purging of English cholera, with the sudden, deadly, overwhelming, collapse, the living death—to use an apparent paradox—of the unhappy being who will probably have perished before my letter closes—if, I repeat, they can confound these symptoms (and I speak but of symptoms, for it is on them they exclusively dwell), I shall, to use the words of an ingenious writer in your Journal on the other side of this question-" For ever after follow the philosophy of the man who doubted his own existence.'

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 76 of the largest English towns 7613 births and 5238 deaths were registered during the week ending Dec. 11th. The annual rate of mortality in these towns, which had steadily increased during the six preceding weeks from 12.0 to 16.5 per 1000, further rose to 16.6 in the week under notice, and exceeded the rate recorded in any week since the middle of April last. During the first ten weeks of the current quarter the annual death-rate in these towns averaged 14.0 per 1000, and in London the mean rate during the same period was equal to 13.8. The lowest annual rates of mortality recorded in the 76 towns last week were 6.4 in King's Norton, 7:1 in Hornsey, and 8:2 in Handsworth and Smethwick, all being suburban districts; the rates in the other towns ranged upwards, however, to 23.0 in Wigan, 24.4 in Ipswich, 24.8 in Barrow-in-Furness, and 25.4 in Coventry. In London the recorded death-rate last week was equal to 16.6 per 1000. The 5238 deaths registered in the 76 towns last week showed a further increase of 42 upon the numbers returned in the six preceding weeks, and included 246 which were referred to the principal epidemic diseases, against 278 and 297 in the two preceding weeks; of these 246 deaths, 67 resulted from whooping-cough, 47 from measles, 47 from diphtheria, 46 from diarrhea, 22 from scarlet fever, and 17 from "fever" (principally enteric), but not one from small-pox. The annual rate of mortality from these epidemic diseases, which had been equal to 0.9 per 1000 in each of the three preceding weeks, declined last week to 0.8. No death from any of these epidemic diseases was registered last week in Leicester, Croydon, East Ham, Oldham, or in 14 other smaller towns; the annual death-rates therefrom ranged upwards, however, to 3 · 0 in Birkenhead, 3 · 2 in Swansea, 4 · 1 in Barrow-in-Furness, and 4 · 2 in Ipswich. The 67 deaths from whooping-cough in the 76 towns showed a further slight increase upon the numbers returned in the two preceding weeks, and caused annual rates equal to 1.3 per 1000 in Sunderland and in Merthyr Tydfil, 1.4 in Ipswich, and 1.7 in Barrow-in-Furness. 47 fatal cases of measles were fewer by 6 than the number in the previous week; the highest annual rates from this disease last week were 1.1 in Swansea, 1.3 in Birkenhead, 1.6 in Northampton, and 2.1 in Ipswich. The deaths referred to diphtheria, which had been 58 and 48 in the two previous weeks, declined to 47 last week, of which 18 occurred in London and its suburban districts, 3 in Bristol and 5 in Manchester and Salford. The 46 deaths attributed to diarrhea showed a considerable further decline from the numbers in recent weeks, but caused proportionally excessive rates in Merthyr Tydfil, Rhondda, and Barrow-in-Furness. The fatal cases of scarlet fever, which had been 41 in each of the target and the scarlet fever, which had been 41 in each of the two preceding weeks, declined to 22 last week, of which 3 occurred in Liverpool and Bootle, 2 in Manchester and Salford, and 2 in Rhondda. The 17 deaths referred to "fever," of which 3 occurred in Manchester, showed a decline of 15 from the number in the previous week. The number of scarlet fever patients under treatment in the Metropolitan Asylums and London Fever

Hospitals, which had declined during the eight preceding weeks from 2810 to 2488, had further fallen to 2475 on Saturday last; 266 new cases of this disease were admitted to these hospitals during last week, against 264 and 281 in the two preceding weeks. The Metropolitan Asylums Hospitals contained 3 cases of small-pox on Saturday last. Of the 1540 deaths registered in London last week, 417 were referred to pneumonia and other diseases of the respiratory system, against numbers increasing from 167 to 432 in the eight preceding weeks; these 417 deaths exceeded by 45 the corrected average number in the corresponding week of the five years 1904-08. The causes of 47, or 0.9 per cent., of the deaths registered last week in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death registered last week were duly certified in Leeds, Bristol, West Ham, Newcastle-on-Tyne, Leicester, Portsmouth, and in 47 smaller towns; the 47 uncertified causes of death in the 76 towns last week included 7 in Liverpool, 3 in Bootle, 3 in London, and 4 in Manchester and Salford.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 790 births and 851 deaths were registered during the week ending Dec. 11th. The annual rate of mortality in these towns, which had been equal to 24 2 and 22 3 per 1000 in the two preceding weeks, rose again to 23 8 in the week under notice. During the first ten weeks of the current quarter the annual death-rate in these Scotch towns averaged 17.2 per 1000, and exceeded by 3.2 the mean rate during the same period in the 76 largest English towns. The annual death-rates last week in these Scotch towns ranged from 12.3 and 15.2 in Greenock and Leith, to 19.8 in Perth and 31.7 in Glasgow. The 851 deaths from all causes in the eight towns last week showed an increase of 54 on the number in the previous week, and included 121 which were referred to the principal epidemic diseases, against 98 and 88 in the two preceding weeks. These 121 deaths were equal to an annual rate of 3.4 per 1000; the mean rate from the same diseases last week in the 76 English towns did not exceed 0.8 per 1000. The 121 deaths from these diseases in the Scotch towns last week included 64 from measles, 16 from whooping-cough, 14 from diphtheria, 11 from diarrhea, 8 from scarlet fever, and 8 from "fever," but not one from small-pox. The fatal cases of measles, which had been 36, 49, and 43 in the three preceding weeks, rose to 64 last week, of which 60 occurred in Glasgow and 4 in Edinburgh. The 16 deaths from whooping-cough were within one of the number in the previous week, and included 7 in Glasgow, 3 in Edinburgh and in Dundee, and 2 in Aberdeen. The deaths referred to diphtheria, which had been 13 and 4 in the two previous weeks, rose to 14 last week, of which 8 were returned in Glasgow and 2 both in Edinburgh and in Paisley. The 11 deaths attributed to diarrhoea corresponded with the number in the previous week, and included 9 in Glasgow. Of the 8 fatal cases of scarlet fever, 4 occurred both in Glasgow and Edinburgh; and 7 of the 8 deaths referred to "fever," were returned in Glasgow, and were all certified as enteric. The deaths referred to diseases of the respiratory system in the eight towns, which had been 298 and 265 in the two preceding weeks, rose again to 275 last week, and exceeded by 160 the number registered in the corresponding week of last year. The causes of 36, or 4.2 per cent., of the deaths in the eight towns last week were not certified or not stated; in the 76 English towns the proportion of uncertified causes of death last week did not exceed 0.9 per cent.

HEALTH OF IRISH TOWNS.

In 22 town districts of Ireland, having an estimated population of 1,142,308 persons, 532 births and 508 deaths were registered during the week ending Dec. 11th. mean annual rate of mortality in these towns, which had been equal to 21 · 0 and 20 · 1 per 1000 in the two preceding weeks, rose to 23.2 in the week under notice. During the first ten weeks of the current quarter the annual death-rate in these Irish towns averaged 18.2 per 1000, whereas the mean rate during the same period did not exceed 14.0 in the 76 largest English towns, and 17.2 in

last week was equal to 22.0 in Dublin, 29.4 in Belfast, 18.5 in Cork, 19.3 in Londonderry, 17.8 in Limerick, and 11.7 in Waterford; the mean rate last week in the 16 smallest of the Irish town districts was equal to 18.6 per 1000. The 508 deaths from all causes in the 22 town districts last week showed an increase of 67 upon the number returned in the previous week, and included 31 which were referred to the principal epidemic diseases, against 18, 21, and 22 in the three preceding weeks; these 31 deaths were equal to an annual rate of 1.4 per 1000; in the 76 English towns the mean rate from the same diseases last week did not exceed 0.8, but in the eight principal Scotch towns it was as high as 3.4 per 1000. The 31 deaths from these epidemic diseases in the Irish towns last week included 19 from whooping-cough, 8 from diarrhea, 2 from "fever," and one each from measles and scarlet fever. but not one either from diphtheria or small-pox. The 19 fatal cases of whooping-cough showed a further increase of 9 upon the numbers in recent weeks, and included 15 in Belfast and 2 in Dublin. The 8 deaths attributed to diarrhoca corresponded with the number in the previous week; 4 occurred in Dublin and 2 both in Belfast and Cork. Of the 2 deaths referred to enteric fever, 1 each occurred in Dublin and Belfast; and the fatal case both of measles and scarlet fever were returned in Dublin. The deaths in the 22 towns referred to pneumonia and other diseases of the respiratory system, which had been 101 and 157 in the two preceding weeks, further rose last week to 162. The causes of 25, or 4.9 per cent., of the deaths registered last week in the Irish towns were not certified; in the 76 English towns the proportion of uncertified causes of death last week did not exceed 0.9 per cent., while in the Scotch towns it was equal to 4.2 per cent.

VITAL STATISTICS OF LONDON DURING NOVEMBER, 1909.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 5.8 per 1000 of the population, estimated at 4,833,938 persons in the middle of the year; in the three preceding months the rates were 5.0, 7.1, and 6.5 per 1000 respectively. The lowest rates last month were recorded in Chelsea, the City of Westminster, Stoke Newington, Holborn, and Finsbury; and the highest rates in Fulham, Bermondsey, Battersea, Lewisham. and Woolwich. Six cases of small-pox, of which 5 belonged to Stepney and 1 to the City of London, were notified during last month, and 4 small-pox cases remained under treatment in the Metropolitan Asylums Hospitals at the end of the month. The prevalence of scarlet fever showed a further marked decline last month; among the several metropolitan boroughs this disease was proportionally most prevalent in Fulham, Bermondsey, Battersea, Camberwell, Lewisham, and Woolwich. The Metropolitan Asylums Hospitals contained 2460 scarlet fever patients at the end of last month, against 2329, 2717, and 2708 at the end of the three preceding months; the weekly admissions averaged 289, against 274, 394, and 325 in the three preceding months. Diphtheria also was less prevalent than in either of the two preceding months; this disease was proportionally most prevalent in Paddington, Fulham, Hammersmith, Stepney, and Lewisham. There were 940 diphtheria patients under treatment in the Metropolitan There were 940 Asylums Hospitals at the end of last month, against 795, 901, and 958 at the end of the three preceding months; the weekly admissions averaged 104, against 119 in each of the two preceding months. The prevalence of enteric fever during November showed no numerical variation from that recorded in the preceding month; among the several boroughs this disease was proportionally most prevalent last month in Kensington, St. Pancras, Bethnal Green, Stepney, The number of enteric fever Poplar, and Battersea. patients under treatment in the Metropolitan Asylums Hospitals, which had been 75 and 78 at the end of the two preceding months, had declined again to 70 at the end of last month; the weekly admissions averaged 10, against 13 and 11 in the two preceding months. Erysipelas was the eight principal Scotch towns. The annual death-rate | proportionally most prevalent in Hackney, Finsbury, the

City of London, Bethnal Green, Stepney, Poplar, Bermondsey, and Deptford. The 29 cases of puerperal fever notified during the month included 5 in Wandsworth, 4 in Fulham, 3 in Hammersmith and in Stepney, and 2 each in Finsbury, Poplar, Bermondsey, and Woolwich. Of the 3 cases notified as cerebro-spinal meningitis 2 belonged to Islington and 1 to the City of Westminster.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the four weeks ending Nov. 27th the deaths of 5131 London residents were registered, equal to an annual rate of 13.8 per 1000; in the three preceding months the rates were 10.5, 11.5, and 11.3 per 1000. The death-rates last month ranged from 7.9 in Stoke Newington, 8.7 in Hampstead, 11.3 in Paddington, in Wandsworth, and in Lewisham, and 11.5 in Greenwich, to 16.0 in Hammersmith, 16.5 in Chelsea and in Bethnal Green, 17.6 in Bermondsey, 18.3 in Finsbury, and 18.6 in the City of London. The 5131 deaths from all causes included 281 which were referred to the principal infectious diseases; of these, 37 resulted from measles, 24 from scarlet fever, 51 from diphtheria, 73 from whoopingcough, 10 from enteric fever, and 86 from diarrhea, but not any from small-pox, from typhus fever, or from ill-defined pyrexia. The lowest death-rates from these diseases last month were recorded in Kensington, Chelsea, the City of Westminster, Hampstead, Stoke Newington, and Lewisham; and the highest rates in the City of London, Hammersmith, Finsbury. Bethnal Green, Stepney, Poplar, and Deptford. The 37 fatal cases of measles showed a decline of 70 from the corrected average number in the corresponding period of the five preceding years; the greatest proportional mortality from this disease was recorded in Paddington, Hackney, Shoreditch, Stepney, Poplar, and Deptford. The 24 deaths from scarlet fever were equal to one-half the corrected average number; this disease was proportionally most fatal in Kensington, Fulham, St. Paneras, and Stepney. The 51 fatal cases of diphtheria showed a decline of 16 from the average number in the corresponding period of the five preceding years; the highest death-rates from this disease were recorded in Hammersmith, Fulham, Bethnal Green, Lambeth, Battersea, Camberwell and Deptford. deaths from whooping-cough were 26 in excess of the corrected average number; the greatest proportional mortality from this disease was recorded in Chelsea, St. Marylebone, the City of London, Stepney, Poplar, Southwark, and Deptford. The 10 deaths referred to enteric fever were 15 below the corrected average number; of these 10 deaths, 2 belonged to Southwark, 2 to Deptford, and 1 each to Westminster, St. Pancras, Hackney, Stepney, Poplar, and Greenwich. The 86 fatal cases of diarrhea were 41 fewer than the corrected average number; this disease was proportionally most fatal in Paddington, Hammersmith, Finsbury, Shoreditch, Bethnal Green, and Woolwich. In conclusion, it may be stated that the aggregate mortality in London last month from these principal infectious diseases was 33 per cent. below the average.

Infant mortality, measured by the proportion of deaths among children under one year of age to registered births, was equal to 118 per 1000. The lowest rates of infant mortality were recorded in Kensington, St. Marylebone, Hampstead, Stoke Newington, Hackney, Holborn, and Lewisham; and the highest rates in Hammersmith, Chelsea, the City of London, Shoreditch, and Bethnal Green.

HEALTH EXHIBITION IN CONNEXION WITH THE CONGRESS OF THE ROYAL SANITARY INSTITUTE.—An exhibition will be held in connexion with the twenty-fifth congress of the Royal Sanitary Institute from Sept. 5th to 14th, 1910, in the Pavilion at Brighton. The exhibition will be divided into four divisions—namely, (1) Science in Relation to Hygiene; (2) Hygiene of Trades and Professions; (3) Construction and Sanitary Apparatus; and (4) Personal and Domestic Hygiene. Full particulars will be supplied on application to the secretary, Parkes Museum, 90, Buckingham Palace-road, London, S.W. The Brighton town council has appointed a subcommittee to make the necessary arrangements for the Congress. It is proposed to call a public meeting of the inhabitants about the end of February.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Surgeon Charles Kendal Bushe has been promoted to the rank of Staff-Surgeon in His Majesty's Fleet (dated Dec. 9th, 1909).

The following appointments are notified:—Fleet-Surgeons: O. W. Andrews to the *Prince George* on commissioning and H. E. Tomlinson to the *Acheron*. Surgeons: H. D. Drennan to the *Hermes*, additional, for the *Odin* and on commissioning; G. D. Bateman to the *Mercury*, additional, for the *Hazard*; G. A. Bradshaw to the *Fermidable*; E. L. Atkinson to the *Pembroke*, additional, for disposal; W. Miller to the *Achilles*; T. Creaser to the *Vectory*, additional for the *Canopus*, on paying off.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel Robert D. Hodson is placed on retired pay (dated Dec. 14th, 1909).

The under-mentioned officers, on transfer from the 8th (Lucknow) Division, have been appointed specialists in the subjects named:—Lieutenant C. H. Denyer, 5th (Mhow) Division, dermatology; Captain P. S. O'Reilly, 9th (Secunderabad) Division, ophthalmology. Major G. W. Tate, M.B., from Dundalk, has been appointed Recruiting Medical Officer at Dublin.

INDIAN MEDICAL SERVICE.

Lieutenant-Colonel R. J. Baker, Bombay, is permitted to retire from the Service. Lieutenant-Colonel A. T. Brown, Bengal, is permitted to retire from Dec. 14th. Captain Norman and Captain White, members of the Plague Research Commission, have arrived at Madras to inquire into the question why Madras and the East Coast generally remained practically free from plague. It is understood that Captain White will be occupied on this work for three or four months. Captain H. S. Matson, Brigade Laboratory, Jhansi, has been appointed specialist in the prevention of disease from Sept. 20th. Captain Lloyd has been appointed acting professor of biology, Calcutta Medical College. Lieutenant E. B. Munro, 62nd Punjabis, has been directed to proceed to Cawnpore for officiating medical charge of the 41st Dogras.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Supplementary List: William Hilgrove Leslie McCarthy to be Lieutenant (on probation) (dated Nov. 17th, 1909).

TERRITORIAL FORCE.

Royal Army Medical Corps.

1st West Lancashire Field Ambulance: Arthur John Evans (late Surgeon, Royal Naval Volunteer Reserve) to be Captain (dated Dec. 15th, 1909).

For attachment to Units other than Medical Units.—Dudley William Carmalt Jones to be Lieutenant (dated Oct. 26th, 1909). Joseph Hollins Donnell to be Lieutenant (dated Nov. 5th, 1909).

THE ARMY MEDICAL ADVISORY BOARD.

The Army Council has approved of the appointments of the undermentioned gentlemen as members of the Army Medical Advisory Board being renewed for a period of three years: Dr. J. Rose Bradford, Sir C. Cameron, Dr. L. C. Parkes, Dr. M. S. Pembrey, and Sir F. Treves.

DEATHS IN THE SERVICES.

Deputy Inspector-General Horace Edward Firmin Cross, R. N., on Dec. 13th, at Tangley Park, Worplesdon, Surrey, aged 60 years. He joined the Royal Navy as a surgeon in March, 1877, and served in the Orontes during the campaign against the Zulus in South Africa in 1877-79 (Zulu medal). He was the surgeon of the Temeraire at the bombardment of Alexandria, July 11th, 1882 (Egyptian medal, with clasp for Alexandria and the Khedive's bronze star). He served with the Royal Marine Battalion during the operations in the Eastern Soudan in 1884 and was present at the actions of El Teb and Tamaai (mentioned in despatches and promoted). In 1892 he was made a fleet-surgeon, and in 1899 a deputy inspector of hospitals and fleets on retirement.

Correspondence.

"Audi alteram partem."

THE PLEA OF LUNACY IN THE CRIMINAL COURTS OF SCOTLAND.

To the Editor of THE LANCET.

SIR,-May I as one engaged in the administration of criminal law in Scotland be allowed to follow up the excellent paper by Professor J. Glaister which appears in your issue of Nov. 13th? He points out some anomalies which have recently emerged, and as the broader question of lunacy administration is likely soon to be taken up by the legis-

lature discussion may be of value.

The first anomaly is that created by the strict reading of the statutes in Brown's case (the case of poisoned shortbread). As Professor Glaister and you in your comments on his article point out, it is not satisfactory that the jury, after having heard not only the evidence as to insanity but also the evidence put forward to establish guilt, should have been barred from considering this latter evidence and from giving a decision on it, by the judge's direction that they should first of all decide whether the accused was at the time of his trial insane in the sense of being unfit to instruct a defence. One would have expected that the jury would have been told that if, having heard the evidence, they did not feel bound to convict they must acquit; that if, however, they could not acquit, then, and not till then, and before convicting, they should ask themselves whether they were satisfied that the accused was in a fit state to instruct his defence. If the evidence is not conclusive against a prisoner either because it is inherently weak or because the defence, however instructed, has been too much for it, what relevance has the question-in many cases an abstract and debateable one-as to whether or not the accused could instruct a defence? Either he has been actually able to do so or it has not been necessary for him to do so. It follows that, assuming the statutes were correctly interpreted, an amendment of them is needed in the interests of fairness.

The question is raised as to whether a preliminary plea of insanity should be decided by a judge sitting alone or by a jury. Much may be said on either side, but one change seems urgently needed. In many cases the fact of insanity is obvious and admitted from the start. There should be some machinery for at once having a judicial ascertainment of it without waiting until a full-blown trial of the whole case can be held. It is not an ideal system which requires that a person who on the face of things has committed no crime, and who may in his normal condition be entirely lawabiding, should be kept for weeks or possibly months in a prison even under the relaxed conditions applicable to untried prisoners, should be associated with criminals of all sorts, and ultimately placed in a criminal dock. I do not know the therapeutics of insanity, but I should be surprised to hear that such treatment was other than highly prejudicial to even a confirmed lunatic, while I can readily understand that it might in some cases be fatal to all hope of ultimate recovery. The further practice of treating such persons after their irresponsibility has been established as criminal lunatics and associating them with those who are criminals first and lunatics thereafter also calls for

The case referred to by Professor Glaister—the Glenbuck murder—where for undisclosed reasons a capital sentence was set aside, raises broader issues. It is not the first time they have been raised, and unless the law is changed it will not be the last. Incidentally the question as to the Secretary for Scotland's position may be answered. It having been suggested that the King should exercise his prerogative on the ground of the prisoner's insanity, it fell to the Secretary to advise His Majesty. He in turn required expert advice and proceeded to procure it. What, however, happened was that a public trial having been held with every appearance of fairness to the accused, and having resulted in a verdict which commended itself with unusual unanimity to the community, its result was set aside by a tribunal of men whose names were not disclosed, whose inquiry was held in

private, and whose opinions were never made public. I must not be understood as cavilling at the ultimate result. It is the method of reaching it which is open to challenge. It is to the credit of our courts and criminal administration that there was no criticism of their part in the case, and, on the other hand, any suggestion that the Secretary for Scotland or his advisers were influenced by outside or undue considerations must be ruled out as quite untenable. The key to the difficulty doubtless is that whereas the trial was in a law court where the medical evidence had to be looked at in the light of certain legally accepted standards to which it had to conform before it established irresponsibility, in the private inquiry no such necessity existed. Looking to the discrepant ideas of lawyers and alienists it is not surprising that different results were reached. Doctors may be excused from congratulating themselves on having thus, even by a side wind, got the better of the lawyers in the long struggle for the relaxation of the legal doctrine of responsibility. I might be inclined to join in their congratulations, but I am chastened by other reflections. It is imperative that our law courts should have the fullest confidence of the people. They cannot have that if their deliberate judgments are set aside in what the people, kept in ignorance of the reason, must regard as an arbitrary manner.

We pride ourselves in Scotland on the fact that our law courts have always shown a readiness to accept the established results of science as soon as there was assurance that they nere established results. As was so well said by the Lord President in Brown's case, "What may be termed scientific opinion on insanity has greatly altered in recent years, and courts of law, which are bound to follow, so far as they can, the discoveries of science and the results of experience have altered their definitions and rules along with the experts." Over 200 years ago Sir George Mackenzie spoke of insanity in a manner peculiarly enlightened for his time and specially remarkable in one who earned the sobriquet of "Bloody Mackenzie." He, of course, accepted the current view that "absolute furiosity" was necessary for irresponsibility, but he went on to suggest that "by the rule of proportions" the punishment should be lessened for those who, not absolutely mad, are "hypocondrick and melancholly to such a degree that it clouds their reason." Further, he speaks of madness as "too sticking a disease and seldom or never cured," and suggests that the judge should remit something of the ordinary punishment for acts done in lucid intervals, because "where madness has once disordered the judgment it cannot but leave some weakness and make a man an unfit judge of what he ought to do"; and he quotes the proverb "once wud (i.e., mad) aye the worse. Mackenzie's dicta strongly recall the latest result of modern thought—the general conclusions reached by Mercier in his book on "Criminal Responsibility" (p. 203)—and it may be taken that they mitigated to some extent the hardships of the old Scottish Criminal Law. Then it is significant that, so long ago as 1863. the answers of the judges, which seem still to dominate English law, were practically discarded in the Scottish courts. Lord Justice Clerk Inglis then told a jury that if they were once satisfied that a person charged with murder was under the influence of insane delusions at the time, they had no occasion to inquire whether he knew what was right from what was wrong or whether he knew what was murder in the eyes of the law or what was a punishable act. Not till 45 years later do we find Mercier, in commenting on the Otley murder case, congratulating himself that it will not now be necessary to prove in our English courts want of knowledge of right and wrong, but only insanity at the time so as to establish irresponsibility.1

To day it may, I think, be claimed that more regard is paid in Scotland than in England to the plea of "insanity of the will," if I may so call it; while in regard to "insanity of the intellect," attention may be called to the direction which the judge gave to the jury in the case of the epileptic, Brown. They were to judge whether Brown was "in the condition of a truly sane man who can not only tell his counsel how to defend him, but can tell his counsel with the certainty of not being deceived what he was really doing at the time when the act charged is said to have been committed." That direction referred to a plea of insanity in bar of trial, but if the same criterion of sanity is to be applied

¹ Journal of Mental Science, October, 1908.

to determine responsibility, then the most advanced alienist must admit that he has got more from the obdurate and conservative lawyer than he ever hoped to get.

The lawyer's position seems sufficiently clear and reasonable. He asks, first of all, for some greater unanimity than as yet exists among mental specialists, and points to the fact that one of the foremost of them in the book just referred to has to admit that his views, though they have been before the medical profession for many years, have not been formally adopted by any other writer. Even where unanimity does exist, he must remember that specialism has its Nemesis and is apt to exaggerate the importance of its own views, and he has to correct that exaggeration by reference to other considerations. He may still claim that the fear of punishment does stimulate self-control, and appeal to the practice of the doctors themselves who punish, at least by deprivations, inmates of asylums who are undoubtedly insane. Lastly, and with great cogency, he may point out that criminal administration must keep in touch with the opinions prevalent in the community, that it is from these opinions that it derives its sanction, and he may say that until public opinion is more ready to acknowledge advanced views on irresponsibility he must be chary of adopting them.

I should apologise for the length of this communication. I proffer the excuse that the lawyer does not often encroach on your space.

I am, Sir, yours faithfully,

Avr. Dec. 6th, 1909.

P. FRASER MACKENNA.

THE STANDARDISATION OF DIS-INFECTANTS.

To the Editor of THE LANCET.

SIR,—The report of THE LANCET Commissioners in the last three issues of THE LANCET has reopened the question whether at the present time the very generally used method of ascertaining the germicidal value of disinfectants devised by myself and Mr. Ainslie Walker in 1902, is capable of being modified so as to give more useful information.

A suggestion in favour of the chemical assay of disinfectants, made by Mr. M. Wynter Blyth at the International Congress of Applied Chemistry in the spring, and a modification of the bacteriological technique published by Dr. Sims Woodhead and Dr. Ponder in the Journal of Pathology and Bacteriology in the summer were the starting points for this Commission's investigation. They finish by finding that only when the influence of several factors mentioned in the report have been determined will it be possible to modify any standard figure (H, p. 1616). I take it, therefore, that this investigation, like many others, had not led to any very definite conclusion, and that the new tests proposed in the report are not suggested as having any standard value.

The Commissioners claim: (1) that they can by a modified method of the chemical test determine the phenoloids present; (2) that the efficiency of an emulsion, provided that it is fine enough to show a Brownian movement, depends on the amount and the chemical constitution of the phenoloids

as shown by the bromine absorption so that $\frac{P-B}{3}$ = germicidal value; (3) that for this relationship to hold good the Rideal-Walker bacteriological test must be performed in a novel manner. With your permission I should like to deal with these three points shortly in this preliminary note.

The method for the determination of the phenoloids is based upon the assumption that all the barium phenolates are very soluble in baryta water; as a matter of fact they must have varying degrees of solubility in this solvent. The ordinary pure carbolic acid, the only substance tried in the control test, happens to be the phenol which, according to the Commissioners' own admissions, is the one which is seldom if ever present in commercial fluids. I have therefore thought it advisable to test the efficiency of the process by taking as a control an emulsion containing some of the higher phenoloids used. My fluid was made up in the same way as that prepared in THE LANCET Laboratory and had by synthesis the following composition: phenoloids, 28.5; resin and fatty acids, 24.0; water and soda, 27.5; hydrocarbons, 20.0. This emulsion corresponds very closer with the trial fluid examined by them, the only marked difference being that instead of pure carbolic acid it contained those phenoloids usually employed.

When examined by the L.A.B. method by myself and also by two other independent chemists, the results were as follows:—

	ĸ.	H.P.	L.
Phenoloids	21 · 3	 18 · 1	 17 ·0
Resin and fatty acids.	24 · 2	 25.3	 25 · 8
Water and soda	30 · 4	 29 · 9	 29 · 5
Hydrocarbons	24 · 1	 26 · 7	 27 · 7

The extraction with baryta is thus open to the very grave objection that the hydrocarbon and barium salts retain a considerable quantity of the phenoloids. I paid special attention to the washing with the baryta as recommended by the Commissioners, and, as will be seen, was only able to obtained 21.3 out of 28.5 per cent. present, but my chemical colleagues obtained even smaller quantities. Owing to this inherent fault it is therefore certain that in different hands differents results are obtained by this process. It is extraordinary that your Commissioners found more carbolic acid than was put into the fluid tested—i.e., 31 5 instead of 30.9 (p. 1457). This can only be attributed to the fact that, as I have already mentioned, the barium compound of pure carbolic acid is more readily soluble when compared with the others. In their control test the carbolic acid found is not only higher than that put in, but higher than that found by the bromine absorption process.

Another important point is that the weight of phenoloids recovered by this process taking the quantities directed is far too small to afford material for a proper examination as to their character. The deficit in the amount of phenoloids found by us is evidently due to the large proportion which remains in the barium salts of the resin and fatty acids. This magma is of a sticky treacly mass and it is impossible to remove from it even with repeated washings with the baryta solution the whole of the phenoloids present. Therefore the method of separation, by means of their barium salts, of the resin and fatty acids from the phenols at any rate in the case of the higher phenols absolutely fails. Owing to these fundamental defects in the process I have not thought it necessary to inquire into the value of the separation by means of acetone of the resin and oils from the precipitate. Another point which affects the accuracy of the process is that the phenoloids are so hygroscopic that it is impossible when dealing with such small quantities as one-third of a gramme to obtain anything like accurate percentages of these substances present. Take, for example, one of the determinations referred to above. Weighed at the moment at which it seemed probable that the ether and water had been driven off as prescribed by the method, 0.309 gramme, or 18.54 per cent., was obtained. After ten minutes this quantity was reduced to 0.303 gramme, or 18.18 per cent., and after a further 30 minutes to 0.293 gramme, or 17.58 per cent. When a difference of 1 milligramme in weight corresponds to 0.06 per cent. and the weight varies by several milligrammes, according to the time occupied in drying it is obvious that, if the separation of the phenols had been complete, the statement of the percentages to the second place of decimals in the analysis conveys a totally erroneous impression of the accuracy of the

It seems also very important that your readers should realise that there are two classes of emulsified disinfectants on the market-viz., those made by means of glue or gum and those made by means of resin or soap and that the process as outlined in the chemical portion of the report is only applicable to the latter of these classes. If, as I contend, and as I think every chemist must acknowledge, the process does not extract the total amount of phenoloids present, it prejudicially affects there disinfect that a second group as conjust these which those disinfectants in the second group as against those which are not tested by the same process. Thus, is it fair to contrast the composition of "Bactox" and "Okol" as stated in the report, seeing that the figures put forward represent their respective compositions as obtained by two different processes, although both are manufactured by the same firm? I feel that it cannot be too strongly emphasised that the analytical data for the various disinfectants given in THE LANCET report, and especially the percentage of phenols on which very far-reaching deductions are based, are obtained not by one uniform method of analysis having a constant error, but by two distinct methods of analysis according to the nature of the emulsifying agent used. The

results from these two methods do not admit of any comparison. The one, as has been shown, gives a percentage of phenols far below the true percentage, the error probably varying with the nature of the resin or fatty acid soaps used; the other, in accordance with common experience, affords results approximately correct, although rather higher than the real percentage.

The results of the analysis of the resin or fatty acids (soap) preparations are therefore not only hopelessly incorrect but are also unfairly compared with the results of the analysis of gelatin or dextrin emulsions obtained by a different method. And further, values have been deduced from the percentage of one constituent or one class of constituents, the phenols thus estimated-without reference either to the wide differences both in the disinfectant and the commercial value which obtains amongst the phenels themselves, or to the equally pregnant facts revealed by the chemical analyses as to the different nature of the emulsifying agents employed. In this portion of the report reference is made also to the great difference in germicidal value which is brought about by the physical character of the emulsion. It is clear also that the neutral hydrocarbons present are not "inert bodies" but must modify the germicidal effect when equal quantities of any given phenol are employed. Neither of these factors has been taken into account in the conclusions based upon analysis.

I have attempted to follow the bromide absorption results, but these have been dealt with by Mr. M. Wynter Blyth in the Medical Officer of Nov. 27th, and I need only say that I concur with him. I pointed out several years ago when working with creolins obtained from different countries that there seemed to be no fixed relation between the germicidal value and the bromine absorption figure, although some of the higher boiling phenols have small bromine absorption figures. I cannot, however, understand why the phenol percentage (assuming that it is correctly obtained by this method), less the bromine value, divided by three should give the germicidal value, as this arbitrary ratio does not seem to be justified by any of the work brought forward by your Commissioners. Take, for instance, the figures given for "Cyllin" and "Cyllin Medical," the phenoloids returned being 40.41 and 32.08 respectively. Even assuming that these phenoloids had the same bromine equivalent, the coefficient given for Cyllin Medical should be higher than that recorded. But we find that the bromine figure for the phenoloids extracted from Cyllin Medical is very much lower than that obtained for the phenoloids of ordinary Cyllin which should still further increase the coefficient of the former. As a matter of fact, from my own personal knowledge the Commissioners are hopelessly wide of the mark in the case of these two disinfectants, not only bacteriologically but chemically. It is easy to be critical, but as on page 1616 they them-

of the validity of their proposal I do not think that your readers can accuse me of being unduly anxious to detract from the merits of the work. If we examine "Cofectant," the first disinfectant given in the table on page 1612, we find this ratio to be 9.3 and the carbolic acid coefficient 9.8 when determined by means of the B. coli and spoons test and compare them with those for Bactox, the other disinfectant, which has a similar coefficient, 9.5, this ratio of $\frac{P-B}{3}$ falls to 6.8. This certainly does not support the contention of the Commissioners, although I believe that the low figure of 6.8 in the case of Bactox may be due to a retention of the phenoloids by the neutral oils. If this is not the explanation, and the manufacturers will be able to say whether it is so or not, we have only to fall back on the fact that the presence of 35.7 per cent. of hydrocarbons in "Bactox" as against none of those "inert bodies" in "Cofectant" causes an increase of germicidal value. I suggest therefore that the L.A.B. method in this case shows that if the amount of active phenols be reduced and replaced by hydrocarbons no interference in germicidal activity is produced. I am naturally gratified by your Commissioners' first bacteriological conclusion-viz., that "the Rideal-Walker method of testing disinfectants certainly gives accurate information under well-defined and strictly limited conditions, but results that can be set down in definite black

selves say that further work is needed on the subject

and white figures are exceedingly difficult to obtain. I have contended all along that these tests to be of any

value must be done by a trained chemist and that many of the errors and disputes in the past have arisen through carelessness or want of skill on the part of the investigator. It is, however, very astonishing that the Commissioners should themselves admit the fact that they could only get 3 out of 11 consecutive tests. The conclusion is an obvious one and makes it possible for me to challenge their statement that no fluid on the market has a higher Rideal-Walker figure than 13. Apart from my own work, there must be thousands of tests now recorded throughout the world showing that for some years Cyllin, and now other manufacturers, have regularly been on the market with a Rideal-Walker figure much higher than that named.

With regard to the modification suggested I have compared the results recorded in the Commissioners' report with those obtained by Ponder and Woodhead when the use of platinum spoons was first suggested for this work.1 A comparison of the table on Disinfectant D with Table XV., McDougall's fluid,2 show that these are the two same tests as the figures are identical with the exception of the misprint of the dilution of 1/1400 in 30 minutes. It is, however, extraordinary that Woodhead and Ponder conclude from this table that Disinfectant D has an average coefficient of 7.4, whilst, when acting as your Commissioners, the same figures show a coefficient of 7.9. If your Commissioners had taken the trouble to repeat this particular table your readers would have been able to judge the accuracy of the process. Fortunately, we have a means of ascertaining the error in the Commissioners' test by the results obtained with Lawes' fluid, Table XIV. (p. 1525). This was called Disinfectant L (Table III.) in the pathological proceedings, and then had an average coefficient of 1.6. We now find that a previous test gave a coefficient of 2·1, and a re-calculation of Table III., Disinfectant L, from the Commissioners' report, Table XIV., gives 1.65. There is thus a very considerable error in this method of control.

Elsewhere I have insisted that any lengthening at the time of the test so as to include a 30-minutes' time of contact is open to the objection that we want disinfectants to act in the shortest possible time. The change of temperature to 62° F. -67° F. is not justified by any scientific rule, nor does it offer any practical advantage. Long experience with the Rideal-Walker test has shown that accidental contamination is not at all likely. I have had none for two years in my laboratory, but this would not apply when working with open pots as suggested. It is an advantage to use a more resistent organism, but one cannot agree that "coli" is less variable than typhoid. Broth is a more delicate test for the recovery of the organism than is bile salt medium.

I have had no opportunity of using the spoons, but think that in some cases a quantity of disinfectant sufficient to inhibit growth the MacConkey tube might be introduced. A novel suggestion that the disinfectant in these small quantities acts as a stimulating tonic is not now referred to by the Commissioners. Moreover, the tubes do not show any improvement through using a spoon instead of a loop. inoculate 12 tests in 2½ minutes with proper mixing must demand great skill, whatever applications be used. regard to the change in the carbolic acid dilutions I may say that I always in my laboratory use stoppers, not corks, and have not noticed a daily disappearance of .003 (.969-.966) in the germicidal value of the carbolic acid. It would have been interesting had your Commissioners ascertained in what space of time that germicidal value entirely vanished.

I am, Sir, yours faithfully, SAMUEL RIDEAL, D.Sc. Lond., F.I.C.

To the Editor of THE LANCET.

SIR,-From the results published in THE LANCET of Nov. 13th, 20th, and 27th respectively, I am able to state with the greatest assurance that THE LANCET Commissioners have not examined "Sanitas-Okol" and "Sanitas-Bactox" as they are at present (and have been for some time past) made and sold, but that the observations were made upon old and superseded preparations. The published results therefore, satisfactory as they are up to a point, do not adequately express the real or comparative values of these two preparations, and I think care should have been taken to avoid such a possibility, either by obtaining the supplies

Journal of Pathology, vol. xiii., p. 152.
THE LANCET, Nov. 20th, 1909, p. 1526.

direct from the manufacturers, or if obtained indirectly there should have been a specification calling for the very latest products sold under the names in question.

Strong objection is also to be taken to the circumstance that in the case of one particular disinfectant referred to in THE LANCET report (Nov. 13th)—viz., "Cyllin," a calculation of value of cost is made based upon the bulk price of that article, whereas the corresponding calculations in respect of "Sanitas-Bactox" and "Sanitas-Okol" are based upon the price of small retail bottles. "Sanitas-Okol" as now made and sold is not a coffee-coloured emulsion, as described in THE LANCET report, and its percentage of active principles is not in accordance therewith, whilst its germicidal value is, I believe, considerably higher than that

expressed in The Lancet report.

Again, "Sanitas-Bactox" as now made contains a much higher percentage of active principles than that given, whilst its germicidal value is correspondingly greater than that expressed in The Lancet report. According to The Lancet "Sanitas-Bactox" contains 39.7 per cent. of phenoloids, whereas as now made it really contains much more, and subjected to Mr. Wynter Blyth's acetone process it shows a content of 54 per cent. Table XXVI. shows "Sanitas-Bactox" to be the cheapest of all the coal-tar disinfectants examined by the Commissioners having regard to germicidal efficiency, but as now made we claim it to be absolutely the strongest quite apart from price, and therefore even much cheaper than shown in THE LANCET report on the basis

Now, with respect to "Sanitas Disinfecting Fluid," which is classified in Group B as a coal-tar disinfectant, your Commissioners must have well known that it is not a coal-tar disinfectant at all, and as the germicidal test which has been imposed is only—speaking generally—applicable to coal-tar preparations, it is absolutely unreliable for adequately testing the disinfectant value of "Sanitas Disinfecting Fluid." "Sanitas Disinfecting Fluid." is quite well known to be derived from the oxidation of hydrocarbons of the terpene class (which are perfectly distinct bodies from phenols, cresols, and phenoloids) in the presence of water, and it may be noted in connexion with the analytical details given by THE LANCET concerning this article that your reporters have apparently overlooked certain important constituents which go off by volatilisation when that fluid is evaporated to dryness.

THE LANCET Commissioners must be well aware that just as the disinfectant values of corrosive sublimate, the permanganates, hypochlorites, sulphurous acid, formaldehyde, peroxide of hydrogen, and many other sanitary reagents, cannot be determined by the bacteriological test which has been used in respect of the coal-tar preparations which have undergone examination at their hands, so also that of " Sanitas Fluid" cannot be measured by any such test, and it is therefore remarkable, to say the least, that this particular preparation should have been singled out for examination by a test not applicable to it, and, further, erroneously described as a coal-tar disinfectant. The scant footnote in THE LANCET of Nov. 27th to the effect that "Sanitas Fluid" was inadvertently classed among tar disinfectants cannot be accepted as a sufficient reparation for the damaging blunder. The measure of utility of any such article is the extent to which it may be satisfactorily employed for the purposes for which it is advocated in accordance with the directions for use printed on the bottle labels, and no experiments or observations of this kind have been made by THE LANCET Commissioners in connexion with that very important and valuable preparation "Sanitas Disinfecting Fluid."

I entirely resent and dissent from the definition of disinfectant value forming the whole basis of THE LANCET report. What has been done amounts to the determination of germicidal values (not disinfectant values) of a number of coal-tar preparations by a particular bacteriological test, comparing the results at the same time with the ascertained percentages of certain contained principles, and in the result no advantage whatever is shown over the so-called Rideal-Walker test. The Commissioners fail, in my view, to properly appreciate the precise relations that exist between germs and disease as they should be viewed from the standpoint of practical disinfection, for while no one questions to-day the fact that many infectious diseases are originated by micro-organisms, yet in certainly 19 out of 20 cases it is absolutely unnecessary to employ strong germicides for 27th, we cannot but ask you to be good enough, if possible,

practical disinfection. There are, of course, occasions on which the use of relatively strong germicides is called for, and valuable preparations are to be found not only in fluids of the coal-tar order, but there are other agents whichare equally valuable, namely, such as perchloride of mercury, permanganate of potash, peroxide of hydrogen, formaldehyde, and so forth, in respect of which, however, the relative values as germicides cannot—as previously pointed out—be determined by the chemical method elaborated by your reporters on the one hand, or by the particular bacteriological test which has been used on the other hand. Butmy view of the matter goes deeper than that, concerned as it is with what has recently been termed a "revolt against the autocracy of the microbe." All along much too little regard has been paid to the opposing circumstances that disease-causing microbes have to overcome before they can establish disease. They do not create disease by their mere mechanical presence, but by the production, through chemical reactions, of certain definite poisonous substances. In other words, it is all a matter of environment, and their presence is more or less a matter of no importance so long as they are prevented from initiating the baneful changes which they are known to be capable of producing only under certain circumstances.

To put the matter in another way, disinfection is not equivalent to the mere destruction of microbes, and germicidal intensity is no measure of the value of disinfectant preparations. Removal by washing is often more efficacious up to a point than destruction by germicides. As THE LANCET has itself recently observed, "there is no factor more favourable to successful invasion of the human body by disease-producing organisms than when the air is rendered stale, warm, and musty," but no one would have resort to the use of strong coal-tar germicides for the purpose of changing the character of such air, but rather to the employ-ment of "Sanitas Fluid" or peroxide of hydrogen, both of which are capable of doing all that is wanted in such case, but neither of which can be regarded as very powerful germicides, using the interpretation placed upon such substances by your reporters.

I go further and may point out that even supposing reliance be placed upon the use of strong germicides, for most applications the disinfectant is first of all diluted enormously with water, by which time the germicidal potency is reduced to a lower level than that of "Sanitas Fluid," which is generally used pure (undiluted) and which has the further advantage of revivifying the air by reason of the activeoxygen which it contains in the form of peroxide of hydrogen. I contend that it is absolutely impossible to determine the relative values of various disinfectants by any one test, nor is such a determination called for either in the public interest or in that of municipal authorities. Disinfectants are many-sided both in character and in action, and comprise all preparations that can be usefully employed either antiseptically or for the destruction by oxidation or otherwise of filth, and generally for preventing the spread of disease. The definition of the term disinfectant is not synonymous with, nor is it to be confined to, mere germicides or poisons.

I shall be glad to know what action you propose to take in respect of this letter and to learn whether you will publish it as an addendum to the report, or procure new samples of our manufactures as now made and sold, with the object of determining their values and publishing the results before you finally close your report, or in what way you will do justice to our legitimate position and interests.

I remain, yours truly, C. T. KINGZETT, F.I.C., F.C.S., (Ex-Vice-President, Society of Public Analysts), Chairman and Managing Director of the Sanitas Co., Limited.

Nov. 29th, 1909.

To the Editor of THE LANCET.

SIR,-Permit us to congratulate you on the public-spirited action which you have taken in appointing a Commission to inquire into the standardisation of disinfectants. entirely from the fact that our disinfectant has passed your standard and been approved by your Commission as a genuine germicide, we think that the work of your Commissioners will be of lasting and very great benefit to the community as a whole.

In reading your issue of Nov. 13th, as well as that of the

to draw attention to the following facts. In the table showing the chemical results you show that our "Cofectant" (regd.) as purchased in an 8-ounce bottle cost 1.31d. per fluid ounce, and 6.6d. per 100 units of phenolic body. In your issue of the 27th you again work it out in this way, cost per ounce being 1.31d., and you give it a comparative cost in pence of 100 units of efficiency, price ratio to carbolic acid equals germicidal ratio to carbolic acid x 100, this working out at 13.4 in the case of "Cofectant."

May we point out that if "Cofectant" is bought in 4-gallon tins it costs 4s. 3d. per gallon, which works out at 0.319d. per fluid ounce. Supposing one adds 33 per cent. for the profit of the retailer, this brings it up to 0.425d. per ounce, divide this by 9.8 × 100, and the figure in your last column becomes 4.33. Again, if purchased in 40-gallon casks, our price is 3s. 9d. per gallon, which works out at 0.2812d. per fluid ounce; add 33 per cent. and this brings it to 0.3742, which divided by 9.8 × 100 gives a price of 0.381d. for your last column. You will see that "Cofectant" bought in bulk is enormously cheaper even than crude carbolic acid.

If you could see your way in justice to us to insert this letter we should be extremely obliged, as when we determined to start in the disinfectant trade we determined to charge only fair manufacturing profits in order that we might supply the public with an efficient germicide at a reasonable price.—We are, Sir, yours faithfully,

EDWARD COOK AND CO., LIMITED.

THOS. ALEX. COOK, Director.

Bow, London, E., Dec. 3rd, 1909.

THE CONGENITAL FACTOR IN HERNIA AND ITS BEARING ON THE OPERATION OF RADICAL CURE.

To the Editor of THE LANCET.

SIR,—In 1899 there was published in THE LANCET a paper by Mr. R. Hamilton Russell of Melbourne on the congenital factor of hernia. The conclusions at which he arrived were set forth as follows: 1. Oblique inguinal hernia is invariably caused by the presence of a congenital sac which in the vast majority of cases is provided by patency of the whole or a portion of the processus vaginalis. 2. There is no evidence in favour of the view that congenital weakness of the abdominal wall in the inguinal region is a factor in the causation of inguinal hernia. 3. While actual weakness of the abdominal wall in the inguinal region is frequently met with and is an occasional cause of recurrence after operation, such weakness is not congenital, but is an acquired weakness due to the existence of the hernia and the use of a truss during a lengthened period. 4. Complete removal of the sac when performed before the abdominal wall has sustained such damage will not be followed by recurrence. 5. The causes of recurrence after operation are three in number-viz., (1) the above-mentioned acquired weakness; (2) incomplete removal of the sac; and (3) traumatism, the

result of misguided methods of operating.

The existence of a congenital factor in some inguinal herniæ is, of course, obvious and familiar, but so far as I am aware no surgeon previously had put forward so sweeping and so consistent a theory and supported it by such cogent and convincing arguments. Although it was opposed to the current doctrines of the text-books and to the practice of most surgeons, this theory made many converts among those who were beginning ten years ago to operate on much larger numbers of herniæ than was formerly thought practicable or advisable, and anyone familiar with the trend of surgical opinion to day as shown in periodical literature, and even in the later text-books, cannot fail to recognise that Mr. Russell's views have made great progress towards general acceptance. Nevertheless, the full importance of the congenital theory and of its bearing on operative practice is not, I believe, as fully realised as it deserves to be. Whether the ordinary inguinal and femoral herniæ are in their essential nature "ruptures," that is, the result of strain, or primarily due to a congenital sac. and impossible without it, is not a matter of mere academic interest but of vital importance in the operation of radical cure. If Mr. Russell is right, as I believe him to be, then

the operation most generally practised in London—viz., that of Bassini or some modification of it—is based on a radical misconception. If we accept the older doctrine embodied in the popular term rupture we accept also the belief that the essential mischief lies in the abdominal wall, and consists of a weak or weakened inguinal or femoral canal, and the chief aim of an operation devised for radical cure must therefore be to strengthen or repair the canal. It is true that all operations for radical cure remove the hernial sac before dealing with the canal, but the method of dealing with the latter is considered the fundamental point of the operation by every surgeon who does not accept the congenital theory.

Since Mr. Russell's first paper appeared in 1899, an important piece of evidence in support of the congenital theory has been brought forward by Mr. R. W. Murray, who, in 200 consecutive post-mortem examinations made upon persons in whom during life there was no history or evidence of hernia, found 68 peritoneal diverticula, of which 44 were femoral, 22 inguinal, and 2 umbilical. This evidence shows that the "pre-existing sac" is no mere hypothesis either for inguinal or femoral hernia. As I pointed out in the course of a controversy with Mr. A. Keith and others in these columns in November, 1906, only one thing remained to carry the congenital theory to its logical conclusion—namely, to show that the radical cure of hernia could be carried out with certainty and success merely by complete removal of the sac without any attempt to strengthen or repair the inguinal or obliterate the femoral canal. Up to that date I had, after dealing thoroughly with the sac, narrowed the external ring by infolding and suturing the external oblique aponeurosis, or the fascia lata in the case of femoral hernia, in all cases except children under puberty. In the latter I had always ignored the canal. From November, 1906, to November, 1908, I had in my hospital clinic 250 operations of radical cure of inguinal and femoral hernia. In all of them but an insignificant percentage the inguinal canal was left absolutely unsutured and the femoral canal was left open except for a simple purse-string suture in the fascia lata and pectineus fascia. In perhaps 2 or 3 per cent. where the hernia was excessively large or complicated by undescended testis the external oblique was sutured so as to narrow the external ring. The patients were discharged from hospital after an average stay of 10-12 days and returned to their work, often laborious work, at the end of four weeks. None wore a truss after the operation. cases were absolutely unselected, included all sizes and durations of hernia and every age from six months to 70 years. As I have shown in previous publications, when recurrence of hernia takes place after operation it appears almost invariably within 12 months of the operation. If, therefore, the closure of the canal is an essential part of the operation, a large number, if not all, of these cases would have recurred long before the present date. At the very least there should have been a greatly increased rate of recurrence. As a matter of fact, only 9 cases have presented themselves, and have all been cured by a second operation. As every case is kept under observation as far as possible for 12 months, and is told to report recurrence at once. I am confident that this number includes practically all recurrences to date. It is noteworthy that they do not include a single case of femoral hernia, and I have not in the whole of my experience had a single femoral hernia recur after operation. In a recent text-book on hernia by Mr. McAdam Eccles (1908) the author remarks: "The operation (for femoral hernia) should be undertaken only with the patient's or the friend's full knowledge that a cure cannot be confidently promised, and that a truss will have to be worn in many instances at any rate for some length of time after the operation has been done.

My own experience has convinced me, on the contrary, that a radical cure of femoral hernia can be absolutely guaranteed, and that the wearing of a truss after an operation for radical cure is merely a confession of failure. I submit that the results in the large number of cases I have quoted above are an absolute proof that the various methods of suturing the inguinal canal are unnecessary in hernia of any ordinary size, and a sufficient proof that the sac and the sac only is the forms or origo mali. The secret of success in operations for the radical cure is complete removal of the sac and the cause of recurrence is the failure to achieve it. If the canal is laid open in order to obtain access to the sac it must

of course be restored by sutures which, far from improving the result, are merely a source of weakness and trouble. As the sac can be completely removed without laying open the canal at all in all but a few complicated cases such as some irreducible hernias and cases of retained testes it is far better to avoid this procedure. By Kocher's method, which I invariably practise, it is perfectly easy first to free the whole sac and afterwards to drag it upwards and outwards until the whole of the lax peritoneum naturally present in the neighbourhood of the internal ring is rendered taut and smooth on its abdominal surface.

In this position it is maintained when the sac is invaginated and pushed through the abdominal wall close to the anterior iliac spine in the manner familiar to all who have looked at the excellent figures in Kocher's "Operative Survery." Anyone who has once seen the ease and quickness with which this manœuvre can be accomplished and the perfect removal of the sac which it achieves I cannot imagine returning to the tedious and misdirected operations which depend for their result on suturing the inguinal canal. In speaking of perfect removal of the sac, I refer, of course, to the neck or upper portion and not the fundus. The neck of the sac is much longer than inexperienced operators suppose. If it is separated from the cord (not merely the vas but all the constituents) upwards to the fall extent the actual junction of the neck with the general peritoneum is marked, as Kocher has pointed out, by a thick pad of sub-peritoneal fat which forms an outlying spur of the prevesical fat. Indeed, to obtain full isolation of the sac it is often necessary to expose and detach the bladder both in inguinal and femoral hernias. Unless this fatty pad is reached and identified a pouch of peritoneum, or at least a pit will probably be left and recurrence is certain. This I believe to be the only cause of failure-viz., imperfect dealing with the sac, and for the benefit of house surgeons and many others to whom I have demonstrated the source of fallacy I have summed up the whole duty of the herniotomist in a few words: the sac, the whole sac, and nothing but the sac.

I venture to commend this little aphorism and the facts which it embodies to surgeons generally. The operation for radical cure of hernia has become, next perhaps to the operation for adenoids, the commonest operation in surgery. It is performed in every hospital, large and small, in the kingdom, and the numbers run into prodigious totals.

If there were less confusion of thought and more simplicity of practice among those who instruct the rising generation of students and practitioners we should hear less of operations which require four to six weeks in bed after-wards, or the "precautionary" use of a truss, or of refusing to operate on people over 40 because of the danger and uncertainty of radical operation. We should be able to agree that the operation is one of the simplest and safest in surgery, that it can be performed at any age, and that the expectation of permanent cure and relief from the nuisance of a truss can be reasonably and confidently put at 95 per cent. if no higher. I believe that the congenital theory of hernia explains and harmonises the anatomical and clinical facts which without it are full of confusion. Its general adoption will necessarily involve greater simplicity and uniformity in the operation of radical cure and will finally banish many of the complicated, misdirected, and imperfect operations which still cumber surgical text-books.

I am, Sir, yours faithfully, EDWARD DEANESLY, F.R.C.S. Eng. Wolverhampton, Nov. 28th, 1909.

THE LISTER INSTITUTE OF PREVENTIVE MEDICINE AND THE WORLD'S GRAPHIC PRESS.

To the Editor of THE LANCET.

SIR,—The governing body of the Lister Institute have noticed with much annoyance that a description with photographs of the Institute has appeared in an advertising pamphlet, entitled "The Petroleum Idea," issued by the Angier Chemical Co., Limited. As the appearance of this description has occasioned some surprise and perplexity amongst the members of the profession to whose notice it has come, the governing body would be grateful if you could find space for the enclosed letter of apology from the World's has found and proved and written that these are just

Graphic Press to the Institute's solicitors which sufficiently explains the circumstances.

I am, Sir, yours faithfully,

CHARLES J. MARTIN, Director.

Chelsea-gardens, Chelsea Bridge-road, London, S.W., Dec. 13th, 1909.

[ENCLOSURE.]

World's Graphic Press, Limited, 36-38, Whitefriars-street, Fleet-street, London, E.C., November 26th, 1909.

Messrs. Hunter and Haynes, 9, New-square, Lincoln's Inn.

9. New-square, Lincoln's Inn.

Dear Sirs,—We are in receipt of your letter of the 19th instant with regard to the photos of the Lister Institute. We are very sorry if we have indirectly caused annoyance to your client who kindly gave us the opportunity of taking the photos of the Institute. We have not seen the pamphlet to which you refer for it was not published by us, but we understand that the photos used therein are photos which we supplied to a firm who asked for them. We stated at the time the permission was granted to us that we required the photos for publication in the Scientific American.

Please accept our sincere apology for the annoyance we have caused your client by supplying the photos to the firm in question. We undertake not to use or supply the said photographs to any journal or person without, in every case, previously obtaining the consent of the Lister Institute.

World's Graphic Press, Limited, Sgn. J. Savory, Secretary.

THE INFLUENCE OF MIND AS A THERA-PEUTIC AGENT.

To the Editor of THE LANCET.

SIR,—In your issue of Nov. 27th. in a letter concerning the therapeutics of suggestion, Dr. E. L. Ash, as I understand him, states that suggestion in most cases will fail unless accompanied by some material form of treatment with the exception of some mental conditions, and adds the further information that this is a matter of practical experience and not theory. It would have been better if Dr. Ash had stated explicitly if this view was the result of his own personal experience, and not left it to be gathered whether it was his or a generally accepted opinion. My own opinion is, and also that of the highest authorities in this method of treatment, that suggestion, unaccompanied by any material form of treatment, is very much more efficacious than Dr. Ash endeavours to make out.

Those medical men who practise suggestive therapeutics with or without the induction of hypnosis do not surround it with mystery, very much the reverse, for they give fullest explanations to their patients concerning the treatment and avoid every appearance of the mystical; but where the treatment is practised by quacks I grant that an endeavour is made to surround it with mystery and occultism. Further, I should like to know what Dr. Ash refers to when he talks about "the more doubtful adjuncts of suggestive thera-peutics" This is casting a serious reflection upon those of us who use suggestive therapeutics with or without the induction of hypnosis, and calls for a definite explanation, which I trust Dr. Ash will be good enough to give, for it is most important that statements such as these should not be allowed to pass without the fullest investigation.

We who practise hypnotic suggestion do not seek to cloak the method of cure by making use at the same time of a material form of treatment, but tell our patients openly that we cure by means of verbal suggestion, and do not let them go away with a false idea that a material form of treatment has brought about the cure, as is so likely to be the case in the method of treatment which Dr. Ash advocates.

I am, Sir, yours faithfully, Douglas Bryan, M.R.C.S. Eng., L.R.C.P. Lond. Leicester, Dec. 8th, 1909.

To the Editor of THE LANCET.

SIR,—The letter of Mr. J. Foster Palmer in THE LANCET of Dec. 4th should not pass without protest, for not only does he deny any virtue to hypnotic influence, but he even accuses it of destroying reason, inducing insanity, and so on, and asks for its condemnation by "all right-thinking persons both in the medical profession and out of it."

To those really experienced in hypnotism Mr. Palmer's opinions appear to be based mainly on empty surmise, and they are hardly good natured. He further declares, for instance, that only the feeble-minded are subject to the influence of hypnotism, when every reliable authority

the subjects who are very difficult, if not impossible, to hypnotise, while the healthiest, body and mind, are the easiest. Nay, more, I have never yet seen a case in which, when properly applied, hypnotic influence has not conferred some amount of benefit, usually most marked and sometimes apparently miraculous. Let Mr. Palmer produce the cases of harm done to substantiate his assertions. There will at least be no difficulty in finding many hundreds illustrative to the contrary.

Recent contributions before learned societies and in medical journals indicate a growing interest and confidence in psychotherapy, including hypnotic influence, and it had need be so when quackery, faith-curing, and Christian Science in the hands of ignorant and unscrupulous operators have recently been gaining a dangerous ascendancy. Would it not therefore be advisable, in the interests of true science and honest professional labour, for some sort of a commission to sit upon the whole question of quackery, faithcuring, and hypnotic treatment? For by the searching inquisition involved under unimpeachable testimony educed we should surely reach conclusions which would serve to deservedly bring forward the true and mercilessly expose the false once for all.

I am, Sir, yours faithfully,

Caterham, Surrey, Dec. 5th, 1909.

HAYDN BROWN.

THE HARD CASE OF THE LONDON STUDENT.

To the Editor of THE LANCET.

STR,-The special articles on medical education appearing in THE LANCET throw much light on this question, but they do not encourage the hope that an equitable adjustment of the weights, carried by runners in the professional race, trained in London, is to be obtained quickly. Towards fairer treatment certainly many proposals have been made, only to arouse instant opposition and maintain the injustice. The institution of a State degree in medicine, recently advocated as meeting the case, does not, as objected, necessarily constitute the anomaly of a one faculty university, and did it do so a more anomalous situation than that now confronting the London medical student would not be created.

Possibly certain bodies may object to the institution of a State degree, fearing it might diminish their utility and prestige, but it can positively be asserted that to certain of them the existing disabilities of the London medical student, if much longer continued, constitute a far more serious menace. Indeed, it is more reasonable to believe that if the medical corporations could by means of the State obtain a degree in medicine for their diplomates their utility and prestige would increase rather than diminish. The alliance in another quarter sought by the two Royal Colleges in London does not appear calculated to enhance their prestige, and as it also does not appear likely to be effected it may not be out of place to plead for less curt condemnation of a State degree in medicine. Particularly so, since another alternative, a new university, seems out of the question. It is merely cruel to taunt London students with the fact that they possess a university already but do not use it; it would be fairer to say that London possesses an Imperial University which does not meet the general needs of London students. I am, Sir, yours faithfully,

Dec. 11th, 1909.

J. H. P. GRAHAM.

THE BRITISH WHITE CROSS MILK COMPANY.

To the Editor of THE LANCET.

SIR,—I have just read an account of a process of dealing with milk intended for consumption in the metropolis at the hands of a company patronised by Lord Lytton which seems to me to be open to criticism. Briefly stated, the process provides for the evaporation of the milk to a fifth of its original bulk, in which concentrated form it is despatched to London where it is diluted with water to make it up to the normal volume.

It strikes one as somewhat ingenuous to expect that milk purveyors will limit their intervention to the strict four-fifths, and even if we concede their honesty we can have no guarantee that the added water will be free from contamination, so that in reality it means opening up a further source

of possible mischief. Moreover, if ever this practice become general it will add greatly to the difficulty of tracing the origin of epidemics which are suspected to be derived from the milk-supply, since it will not be the milk-supply that has to be inquired into but a series of water-supplies.

I am, Sir, yours faithfully,
ALFRED S. GUBB, M.D. Paris.

Mustapha Supérieur, Algiers.

THE THERAPEUTIC VALUE OF LIQUID AIR AND SOLID CARBON DIOXIDE.

To the Editor of THE LANCET.

SIR,—I am much interested in the criticisms of Dr. Stopford Taylor and Dr. R. W. MacKenna regarding what I have said as to the relative advantages of liquid air and solid carbon dioxide in my paper published in THE LANCET of

Reading their letter leaves me with the impression that they have not used carbon dioxide to any great extent, and that when they do it is not compressed as hard as I consider it should be to get the best results. It should be so hard that a fragment, say, as large as a filbert, thrown into cold water immediately sinks. With such a crayon, and proper adjustment of the two important factors of time and pressure, I have found it possible to get practically any desired depth and intensity of action, and as this varies from a mild and passing hyperæmia to a complete necrosis I quite fail to see how liquid air or any other freezing agent can do any better. An application of liquid air, even made in the manner described by your correspondents, is necessarily a transient one on account of the very short time it remains liquid under those conditions, and though the effect is very vigorous while it lasts, it cannot extend very deeply. With solid carbon dioxide, on the other hand, the application may last any length of time ever likely to be required without any fear of the supply giving out, and its temperature remains constant to the last. In addition to this, carbon dioxide is easier to obtain, easier to manage, very much cheaper, and a large cylinder of the liquefied gas, as used in the mineral water industry, can be kept on hand ready for use at any time, which cannot be done with liquid air.

It may interest your correspondents to know that while liquid air has been used to a considerable extent in the London Hospital, it has been almost entirely superseded by solid carbon dioxide on account of the superior advantages I am, Sir, yours faithfully, of the latter. REGINALD MORTON.
Upper Wimpole-street, W., Dec. 13th, 1909.

ADAMS v. POMEROY: AN APPEAL.

To the Editor of THE LANCET.

SIR,—The case of Adams v. Vanity Fair and others is of considerable interest to the medical profession. action was originally brought against Vanity Fair, Limited, the editor of Vanity Fair, the printers, the publishers, and the writer of the article, Mr. Ernest Pomeroy. The first four made and published a full apology to Dr. Adams. which she accepted on condition that they paid costs up to the date of their apology, so that, at an early stage of the hearing, proceedings were stayed against all except the lastnamed defendant, Mr. Ernest Pomeroy.

The article which formed the basis of the Adams libel action was published in Vanity Fair on Oct. 7th, 1908, and it is typical of the attacks previously made by Mr. Pomeroy against the medical profession, particularly in connexion with the subject of vaccination. It contained scandalous and absolutely untrue statements regarding the whole medical profession, and suggested an imputation against Dr. Adams personally which, if true, would necessitate her exclusion from the profession on the ground of infamous conduct. She strongly resented the general as well as the personal attack, and, in our opinion, she rendered a public service by her action in bringing the defendant into court at her own risk and exposing his methods. We believe that this view will be generally endorsed and that many members of the profession will be glad to show their appreciation of the trouble and anxiety incurred by Dr. Adams,

largely from altruistic motives, by contributing to a fund for the reimbursement of her out-of-pocket expenses.

After the judge's summing up, which contained a scathing criticism and condemnation of the writer of the article, and in which he emphasised the point that the individual opinions of the jury on the merits or demerits of vaccination ought not to affect their verdict, the finding of only \$\frac{1}{4}d\$. damages came as a surprise to those in court. The taxed costs will not cover all the legal expenses which Dr. Adams has incurred, so that there will be a deficit of at least £100.

Contributions are invited, and may be sent to the honorary secretary of the Adams Fund, Dr. L. Garrett Anderson, 114A, Harley-street, London.

We remain, &c.,

A DISCLAIMER.

To the Editor of THE LANCHT.

SIR.—A report has recently appeared in certain papers of some proceedings in the Law Courts against a Mr. Dudley Wright. Several persons have been misled into thinking that this refers to our client, Mr. Dudley D'A. Wright, F.R.C.S., of 3, Bentinck-mansions, Bentinck-street, and we should esteem it a favour if you would be good enough to insert in your next issue a statement to the effect that our client is in no way connected with the defendant in the proceedings we have mentioned. One report of the case to which we refer appeared in the Daily Telegraph of the 6th inst.

We are, Sir, yours faithfully,
F. KIMBER BULL AND DUNCAN.
6. Old Jewry, London, E.C., Dec. 10th, 1909.

ANNUAL MEETING OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

To the Editor of THE LANCET.

SIR,—Every Fellow of the College becomes a Member as soon as he becomes a Fellow, so that I fail to see any point in the communication which you published last week under this heading from the honorary secretary of the Society of Members of the Royal College of Surgeons of England.

I am, Sir, yours faithfully,

Dec. 14th, 1909.

A MEMBER.

ALVARENGA PRIZE OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA.—The College of Physicians of Philadelphia announces that the next award of the Alvarenga prize, being the income for one year of the bequest of the late Senor Alvarenga, and amounting to about 180 dollars (£36), will be made on July 14th, 1910, provided that an essay deemed by the committee of award to be worthy of the prize shall have been offered. Essays intended for competition may be upon any subject in medicine, but cannot have been published. They must be typewriten, and must be received by the Secretary of the College on or before May 1st, 1910. Each essay must be sent without signature, but must be plainly marked with a motto and be accompanied by a sealed envelope having on its outside the motto of the paper and within the name and address of the author. The successful essay, or a copy of it, shall remain in possession of the College; other essays will be returned upon application within three months after the award.

THE POOR-LAW MEDICAL SERVICE IN FRANCE.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

THE NEW FRENCH METHOD PROMOTED BY THE MEDICAL UNIONS TO SECURE FOR THE POOR THE FREE CHOICE OF MEDICAL ATTENDANTS AND THE PAYMENT OF THE MINIMUM MEDICAL FEES BY THE MUNICIPALITIES.

THERE are in France unions or syndicates which, commencing as local organisations, have gradually federated together, so that to-day 8000 medical men belong, not only to their local union, but also to l'Union des Syndicats Médicaux de France. The mission of these syndicates is to defend the interests of the medical profession from the economic, legislative, legal, and social points of view. They seek to uphold the dignity of the profession, to defend medical men when unjustly prosecuted, to influence legislature when dealing with matters in which the profession is concerned, and generally to promote the corporate interests of medical men. Of late years one of the principal questions with which it has been necessary to deal relates to the medical relief of the indigent. While in England we are discussing how our Poor-law should be altered and improved our neighbours are endeavouring to create something like a Poor-law. In England every necessitous British subject has a right to claim relief and theoretically, at least, need never starve. No such right exists in France. There are State instituted and subsidised charities and relief bureaus that give a great deal of help, but the French citizen has no absolute right to such assistance. Certainly a law was enacted on July 15th, 1893, that was meant to confer upon all the right to receive medical assistance. But this law does not give the necessary directions as to the method of administration of such relief. It merely orders the Conscillers Généraux or county councillors to provide medical assistance in such a manner as will best serve the interests of the patients and of the public funds of the district and county authorities (communes et départements). Such vagueness has naturally produced a great divergence in the methods adopted by the various local

The medical unions, on their side, however, have fortunately entertained no difference of opinion. Even those medical men who had not thought over the matter and had no clear ideas of their own were very promptly indoctrinated by the unions to which they belonged and thus throughout all the disputes that have followed the profession has not failed to present a united front. The principle on which all are absolutely agreed is embodied by the one word freedom. The patient shall be free to choose the medical attendant he prefers, and the medical practitioner shall be free to undertake that sort of practice if it suits his convenience or interests. If a medical man be willing to take such cases and if he be fully qualified, then the mayor, or whatever other authority may be in charge of this service, must not refuse to put his name down on the list of medical men from which the poor have the right to select their medical attendant. Thus far it was easy to agree, but the question of remuneration was not so readily settled. Yet in principle that was also quickly arranged. There should be the minimum fee when the patient was able to consult the medical practitioner at his surgery, then a larger fee when the patient was seen in his own house if within one kilometre, and an increase for every kilometre beyond. The lowest fees suggested under these heads were 1 franc and 1.50 francs and 50 centimes per kilometre respectively, but many practitioners thought these sums far too low. Night visits were to be charged extra and all surgical operations according to the tariff under the law on accidents to workmen.

The local authorities did not in every instance endorse the views of the medical profession. They had ideas of their own, and having the undisputed authority proceeded to apply them. In many instances they adopted the system of the friendly societies. As soon as a person had established his claim to gratuitous medical assistance his name was placed on the list of a certain practitioner, and a small sum, a very small sum, sometimes only 2 francs, or 1s. 10d., was paid for him per year to this practitioner. This system resembles the club system in England, except that the remuneration is even less.

and the patients being supposed to be paupers the payments are made by the municipality. Apart from the insufficiency of the remuneration, which is, however, a minor consideration, the great objection is that, while the medical man is converted into a salaried functionary the patient is deprived of the free choice of his medical attendant. Then further, the system lends itself to abuse, generally of a political character. A mayor may be tempted to put patients on the free list so as to secure their votes at the next election, and he may inscribe these patients on the list of the medical officer whom he wishes to influence in his favour, though the profits to be obtained from such practice must be slender. In rural districts, where the allowance for travelling adds considerably to the fees paid and where there are very few well-to-do patients, this poor practice is of importance. Even where the free choice of the medical adviser is established in principle it is not always applied in practice. For instance, Dr. Ed. Duchemin, practising in the department of the Côtes-du-Nord, relates that in many communes the mayor inscribes, or causes to be inscribed, on the ticket given to the patient certifying that he is entitled to gratuitous medical attendance the name of the medical man he is to consult. This is, of course, absolutely contrary to the regulations; it is for the patient himself to write in the name of the medical practitioner he On being questioned why they thus transgressed against the rule the mayors generally replied that the poor people were very embarrassed when called upon to make a choice. The weakness of this excuse becomes manifest when, on examining the choice made by the mayor, it proves to be in favour of some active political supporter or of a member of his own family. Such nepotism is inevitable whatever may be the system adopted so long as the patient is not given absolute freedom of choice.

The law of 1893, though susceptible to abuse, would be favourable to the interests of the medical profession if properly applied. It should put an end to the very extensive gratuitous attendance on the poor which falls to the lot of most practitioners. For all such attendance the public authorities have now to pay, a very small fee it is true, but nevertheless some return for frequently arduous work. On the other hand, there is the danger that some persons who are not poor, who could afford to give fees, will be put on the free list from motives of favouritism. The medical profession would therefore lose the better fees which these people as private patients would have to pay. Then there still remains a number of persons who are really unable to give anything and yet are too proud to apply for a ticket for medical attendance at the public cost. Such patients make promises they cannot fulfil, and thus in spite of the new law the medical practitioner finds that he has been working for nothing. There is, however, a way out of this difficulty. When the practitioner feels convinced that his patient is too poor to pay he can himself go to the town hall and demand that his patient be enrolled on the free list. Such a request when made by the medical practitioner himself is very rarely refused. Thus it amounts to this, that when the patient does not pay the municipality must do so in his stead. Of course, the municipality only pays the minimum fee and could easily recover the amount from the patient if the latter was only pretending to be poor.

Dr. Proby, of Oullins (Rhône), in l'Avenir Médical, suggests that when called to a patient who is manifestly unable to pay, he should be urged to claim his right to medical relief. It should be explained that this is no charity, but a right recognised by law, that everyone has to pay additional taxation so as to be insured against the extreme misery of having no medical assistance when ill. If the local authority hesitates to grant this right then application must be made to the representatives of the central authority—namely, the prefect of the department. The prefects are complaining that the law is not yet effectively applied, that many still suffer for want of proper medical attendance, and that the small local authorities are negligent; but the prefects cannot interfere on behalf of the poor unless the poor themselves complain. It would therefore be well if medical practitioners explained to the poor what are their legal rights. Dr. Proby argues that if a State or a nation offers medical attendance and medicine gratuitously to the poor this is done from praiseworthy motives of humanity, but there is also

to preserve for the benefit of society the health of its workers, for this constitutes the most precious national asset. Especially is this the case in France, where there is no increase of population. Dr. Proby is very clear that the patient should have the right to choose his He says:--"Because a patient is in such unfortunate circumstances that he cannot afford to pay for a medical attendant, that is no reason why he should be deprived of the liberty of disposing of his own person. Do we not know that the confidence of the patient is the practitioner's most useful ally? Would it not be odious to impose a doctor on a sick man who must listen to the story of all his suffering, to all his confidences, all his secrets, who must bring him consolation even if he cannot cure him, when this doctor, rightly or wrongly, is not trusted but absolutely disliked by the patient?'

It is assuredly sound economy to see that the sick poor have medical attendance early, for otherwise their diseases will be aggravated and they will end by going to a hospital, where they will cost the community a much larger sum. The better the attendance given at the patient's home the less will be the pressure on the hospitals. If medicine and efficient medical attendance is provided gratuitously, many patients now taken to a hospital might remain in their homes surrounded by their families. This would cost less, especially in France, where nearly all the hospitals are municipal hospitals. But, of course, a patient is not so likely to receive good treatment at home if his medical attendant is not properly paid for his trouble. any case, the medical attendant will seek to get rid of a troublesome patient by passing him on to a hospital. Thus from all points of view it is best policy to give full satisfaction to the claims brought forward by the medical syndicates, particularly as the medical practitioners who have not joined these unions are often consulted. Thus, for instance, in the department of the Cher there are 110 practitioners, some of them in the union, whilst some have not yet joined. Before communicating to the prefect and demanding the recognition of the principle of the free choice of the medical attendant by the poor in receipt of relief, all these practitioners were asked to state whether or no they supported this principle. The result of this plebiscite of the profession was: "Yes," 83 votes; "Yes, but with some conditions," 8; "No," 5; "Failed to reply," 14. In the course of time, and after the result of this vote had been submitted to the prefect, he agreed to negotiate with the Medical Syndicate so as to arrive at a common understanding with regard to the gratuitous medical service. Altogether and throughout France the principle of the free choice by the poor of their medical attendant has been admitted in 63 out of the 86 or, if the colonies are included, the 91 depart-But there have been many struggles and local medical strikes to bring about this result.

As an illustration of the way the system of medical poor relief works, a petition sent to its county council by the bureau of the medical syndicate of L'Ille-et-Vilaine be quoted. This department, which has the town of Rennes for its capital and is well known to the English frequenters of St. Malo, possesses a total population of 611,805 inhabitants. Of these 50,817, or 8.30 per cent., receive poor relief. The outlay for public assistance is 262,131 francs (£10,525) per annum. This equals an expenditure per inhabitant of 0.43 franc, or 44d.; or of 5.17 francs (4s. 14d.) per recipions of relief. Out of this total arrangilisms. recipient of relief. Out of this total expenditure, 89,150 francs, or 0.14 franc per inhabitant, or 1.75 francs per person relieved, are paid to the medical men in attend-The department occupies the thirty-first rank in order of corporate wealth, and the third place as regards the number of persons relieved out of the 54 departments for which the necessary statistics are obtainable. In the department of the Loire-Inférieure, of which Nantes is the principal town, there is a population of 666,748 inhabitants, but only 38,441 receive poor relief, and in the Côtes-du-Nord, with 611,508 inhabitants, not more than 26,551 receive relief, yet it is placed as low as the seventy-first amongst French towns in respect to the wealth of its populations. In the Calvados those who receive poor relief cost 29.25 francs, in the Loire-Inférieure 19.60 francs, in the Côtes-du-Nord 11.58 francs, in La Manche 7.20 francs, and in Ille-et-Vilaine another reason. Such relief is given not only for the sake of those who receive it—there is a higher and more general interest to be served. The object is department of L'Ain the medical attendant receives 4.35

francs on an average for every patient in receipt of medical relief. In 11 departments, out of the sum spent on each individual in receipt of poor relief, the medical attendant receives as his fees an average of 5 francs, or 4s.; in 22 departments he receives from 7 to 8 francs, in 11 departments from 8 to 10 francs, and in 12 departments from 11 to 13 francs. Out of the 54 departments that have supplied statistics 40 have adopted the principle of the free choice of medical adviser.

The chief objection alleged against this method is its greater expense. The poor, it is said, will naturally select the practitioner who treats them with the greatest kindness, and is easily induced to prescribe agreeable stimulants and restoratives; that therefore the bill for drugs and for relief in kind will be augmented. But there is no difficulty in establishing beforehand what sort of prescriptions may be made, and experience has shown that other systems are at times quite as expensive. Again, it is not as if these pauper patients represented a mine of gold. At best the remuneration for attending them is so very small that it does not constitute a sufficient temptation to induce a medical practitioner to go out of his way to secure their preference. Consequently it seems very likely that in course of time all the local authorities in France will apply the methods which have already been accepted by the large majority of county and district councils. The cost in France is generally borne by all three tax-collecting authorities: the commune, which in England we should call the rural or urban district council or borough; the department, or county council; aided, where there is special need, by subventions from the State. By indirect taxation, and especially by the octroi (or town dues), the poor pay a larger proportion of their incomes in taxation than the wealthy classes. The tendency is to look upon taxation more and more as a form of insurance against sickness and poverty and the other ills of life. The medical profession, by the voice of its representative organisations, declares that it endorses heartily all such social legislation, and its members are quite willing to pay the increased taxation in common with other citizens. But having thus subscribed its full share there is no reason why the medical profession alone should be expected to contribute further by attending on the poor without adequate remuneration. All other persons concerned are paid. The butcher, the baker, the grocer, who provide for the food, the clerks of the "Public Assistance" are all paid, and paid at the usual rate. The medical man alone is expected to give his services for nothing, or for next to nothing. But a great improvement will have been realised if henceforth the municipality is bound to pay when the patient fails to do so. The medical practitioner will then be sure of receiving at least the minimum fee. If the patient objects to the stigma of pauperism he has only to pay the fees and his name would at once be effaced from the free list kept at the town hall.

The following things will certainly bring about a very great change in the position of medical practitioners: Firstly, that no one, whether rich or poor, shall suffer for want of medical assistance; secondly, that the sufferer shall choose his medical adviser; thirdly, that the medical adviser shall receive at least the minimum fee, if not from the patient then from the municipality. This is certainly a very simple and vet a very thorough scheme of medical poor relief. Nor is this merely a scheme; its application is now in course of development. It has met with the almost unanimous approval of the medical profession of France and is endorsed by the great majority of the local authorities which administer the public funds destined for the relief of the poor.

PREGNANCY AND EMPLOYMENT.—Our Paris correspondent writes that a statute relative to the employment of female workers during pregnancy has just been passed in France. It provides that absence of a woman from work for eight weeks covering the period which precedes and follows her delivery shall not entail dismissal by her employer on the ground of breach of contract. The woman shall inform her employer of the reason of her absence. Any agreement waiving her rights shall be void in law. In the event of dismissal by the employer she shall be entitled to claim damages from him.

THE 1909 CHOLERA EPIDEMIC IN EUROPE AND SPORADIC PLAGUE IN THE NEAR EAST.

(FROM THE BRITISH DELEGATE TO THE CONSTANTINOPLE BOARD OF HEALTH.)

Cholera in Russia.

THE cholera returns for all Russia (excluding St. Petersburg) in the last few months are summarised in the following

Between	July	5th	and	July	11th		(858)	cases,	384	deaths)

(All the above dates are according to the Old Style.)

In this table the figures given within parantheses are uncorrected, and consequently considerably below the truth. During the present epidemic the Russian authorities have published weekly returns, but the figures given for one week have invariably been corrected during the subsequent week, and the result of this correction has always been to add something like 20 or 25 per cent. to the figures issued the previous week. For the first two and the last three weeks included in the above table I have only been able to obtain the uncorrected figures. The above returns, moreover, do not include the figures for St. Petersburg and suburbs, which have been as follows, since the disease appeared there in May last:—

Week ending-	Cases.	Deaths.	Week ending-	Cases. Deaths.
May 23rd	23	12	Aug. 15th	172 81
" 30th	58	19	22nd	172 72

Aug. 1st	210	7 7	" 24th	81 20
" 8th	195	71		

(In this table also the dates are according to the Old Style.)

The total figures for St. Petersburg down to Oct. 24th (Nov. 7th) had, therefore, been 6184 cases and 2368 deaths. The totals for the rest of the Russian Empire down to the same date had been 19,054 cases and 8485 deaths.

The present epidemic of cholera in Russia, like those of 1907 and 1908, has been very widespread, as shown by the following facts. Beginning in the city of St. Petersburg in May, it had by the first week in July extended to the following governments: St. Petersburg, Vologda, Arkhangel, and Olonetz in the north; Novgorod, Pskof, Vilna, Vitebsk, Courland, Livonia, and Finland in the west; Moscow, Yaroslavl, and Riazan in the centre; Viatka in the north-east; and Simbirsk on the Volga. In the week ending July 11th, the governments of Kharkof, Tver, Esthonia, and Kostroma were added to the list, and in the two following weeks those of Tula, Mogilef, Poltava, and Kherson. Then, in the week ending August 8th, the disease spread to the governments of Nijni-Novgorod, Samara and Saratof on the Volga, and to that of Perm, in the extreme north-east of European Russia. In the week ending August 15th it appeared in the Siberian government of Tomsk, and in that and the next two weeks it extended to the governments of Smolensk, Kovno, Kief, Ekaterinoslav, and the

Taurida. In the week ending Sept. 5th the governments of Minsk, Astrakhan, Voronezh, and Kazan first appeared in the list, and the presence of the disease was announced in Vladivostok, on the Pacific. (It would seem possible, even probable, that the infection in Vladivostok came from some centre in the Pacific, rather than by an extension from the west through Siberia, since none of the other Siberian governments, save that of Tomsk, have figured at any time in the weekly returns). In the week ending Sept. 12th cholera appeared in the governments of Grodno, Suvalki (Poland), and Ekaterinoslav; in that ending Sept. 19th Baku, on the Caspian, became infected; in the week ending Sept. 26th the governments of Tchernigof, Kaluga, and Tambof; in that ending Oct. 4th the town of Derbent (in the Caucasian province of Daghestan); and finally, in the week ending Oct. 24th the government of Volhynia appeared for the first time in the lists. Mention should also be made of an outbreak of the disease, in the last week of the series, in Yalta, on the shores of the Crimea.

The intensity of the epidemic has, of course, varied considerably in different parts of the country. It has been particularly persistent and severe in the capital, the figures for which were quoted above; and in the governments of St. Petersburg (1324 cases, 726 deaths), Arkhangel (744 cases, 381 deaths), Vitebsk (3390 cases, 1315 deaths), Tver (728 cases, 332 deaths), Yaroslavl (985 cases, 512 deaths), and Novgorod (768 cases, 358 deaths). The governments on the Volga have this time been comparatively lightly visited. In the more outlying parts of the empire it may be noted that 63 cases and 27 deaths have occurred in Baku; that in Derbent (Daghestan) there has been only 1 case and 1 death; in Finland only 10 cases and 5 deaths; in the Tomsk government (Siberia) only 2 cases and 1 death; while in Vladivostok, on the other hand, there have been as many as 142 cases and 94 deaths. (In each case the figures just quoted refer to the period between the beginning of the epidemic and the week ending Oct. 24th, Old Style). As on previous occasions, the present epidemic in Russia has been characterised here and there by the occurrence of "cholera riots" in a few villages, and by the carrying out in others of some very curious superstitious and practically pagan rites, intended to conjure away the evil demon of the disease.

A Case of "Laboratory Cholcra."

The Russian medical journal, the Vratch, published in July last the following interesting details of a case of cholera contracted in the course of laboratory work. A lady student working in a laboratory in St. Petersburg was investigating the agglutination characters of a cholera vibrio isolated from a sample of water taken from a manufactory in the city. By accident some of the contents of a pipette entered her mouth. In spite of immediate efforts to disinfect the mouth, a typical attack of cholera followed, and the dejecta were found to contain enormous quantities of comma vibrios. Fortunately the patient recovered. The incident is a most instructive one, and the conclusions to be drawn from it are obvious.

The Pilgrimage and the Cholera Epidemio.

The fêtes of Kurban Bairam will take place in about three weeks from now. The contingent of pilgrims from the north has not been a very large one this year. They have been subjected to the necessary measures in the Turkish lazarets of the Black Sea and Mediterranean, and so far there has fortunately been no case even of suspected cholera among them. A suspicious death, however, recently occurred on board a sailing ship arriving at Kopmish, on the Russo-Turkish frontier east of Trebizond. The ship had come from some of the Russian ports on the eastern shores of the Black Sea.

Cholera in Persia.

Within the last few days it has been reported that cholera has appeared in the Persian portion of the (double) town of Astara, situated just where the Russo-Persian frontier comes down to the shores of the Caspian.

Cholera in Germany.

In view of the prevalence of cholera in the Baltic provinces of Russia it is not surprising that the infection has spread to the adjoining districts of East Prussia. The following details have been communicated officially to the Board of Health here. On July 20th a passenger arrived by train at

the following day from cholera; the diagnosis was confirmed bacteriologically. On Sept. 18th a German raftsman died from cholera at Pokalina, Heidekrug (East Prussia), and his wife was attacked by the disease. The infection was believed to have been brought by timber rafts floating down the Memel from Russia. In these cases also bacteriological evidence confirmed the diagnosis of cholera. A sanitary station was opened at Schmalleningken, on the Memel. A Berlin telegram, dated Oct. 29th, stated that since Oct. 9th the following cholera cases and deaths had occurred in the basin of the Memel: in three places in the Heidekrug district 7 cases and 2 deaths; in two places in the Niederung district 11 cases and 2 deaths; and in that of Tilsit Land 1 fatal case. Measures had been taken, it was added, for the sanitary control of the river. Between Oct. 29th and Nov. 5th 3 cases occurred in one place in the Heidekrug district, 3 cases in two places in the Niederung district, and 4 cases in the Labian district. The two former districts are in the prefecture of Gumbinnen, and the last in that of Königsberg.

Cholera in Holland.

At the end of August news was received here that cholera had appeared at Rotterdam. From August 20th to Sept. 1st 25 cases of the disease were seen in that town, and 3 in other places in the Dutch provinces. About the same time 2 cases were reported from the neighbourhood of Amsterdam. From Sept. 1st to Sept. 7th 24 cases were observed in all Holland, of which 20 occurred at Rotterdam, and single cases at Middelburg, Utrecht, Breda, and Helsteren. Later information showed that the disease broke out first in Rotterdam, where, on August 20th, four persons died in one family alone. A bacteriological inquiry showed that they had died from veritable cholera. On Sept. 10th a case of the disease was reported from Dirksland and another from Amsterdam. No case had occurred in Rotterdam since the 4th. A telegram of Sept. 28th stated that "a second case" had occurred in Hanswert, the two patients being husband and wife, hairdressers, who took in boatmen as lodgers. Still later telegrams showed that a third case occurred in this family at Hanswert, that two cases had been seen at Lopik, and that at Hattom (near the Zuyder Zee) 4 cases with 1 death had occurred in one family. On Oct. 20th a fatal case of the disease was seen at Yaarsveld, in the Utrecht province, and a second case in the same family followed on Oct. 25th. Since then no further news has been received here concerning cholera in Holland.

Cholera in Belgium.

A telegram from the Ottoman Consul in Antwerp was received here early in September, stating that on Sept. 4th a boy, aged 14 years, had died in the village of Lillo, north of Antwerp, from fulminant cholera, and that his brother, aged 16 years, was attacked with the same disease; both were sons of the owner of a boat that had come to Lillo from Utrecht. In the former case a bacteriological investigation could not be carried out, but in the latter such investigation was made and showed that death had been really due to Asiatic cholera. It was further stated that on August 29th the owner of a barge coming from Rotterdam to Lillo had died from a suspicious disease, but that a bacteriological examination had given negative results. A later report from the same source, dated Sept. 28th, stated, on the authority of the Governor of the Antwerp province, that "none of the cases till then reported in Belgium had been confirmed bacteriologically"—a statement in direct contradiction of the earlier reports. A month later (Oct. 29th) the same consul telegraphed that, from personal inquiries, he had established that at a distance of 17 kilometres from Antwerp there had occurred in the course of eight days nine cases of Asiatic cholera with six deaths. Two days earlier the Belgium authorities had officially admitted that some cases of the disease in which the cholera bacillus had been found had occurred in the Antwerp province. It was believed that the infection had come from drinking water on board certain barges coming from Holland and touching at places on the banks of the Escaut.

Cholera in Galicia and Moravia.

On July 28th the Ottoman Embassy at Vienna telegraphed that a suspicious case had been seen at Lemberg, and in later telegrams, dated August 24th and 30th respectively, the same authority reported a suspicious case at Napagedl in Königsberg, coming from Russia. He was already ill and died | Moravia, and a fatal case of Asiatic cholera in Galicia, the name of the place where it had occurred not being mentioned.

Plague in Adalia.

It will be recalled that, as stated in my last letter on this subject (published in The Lancet of August 21st, p. 576), 5 cases of plague, with 3 deaths, occurred at Adalia in July. After the 29th of that month no further case was seen until Oct. 25th, when 2 fresh cases were reported. The patients were the son (aged 4 years) and the servant (aged 15 years) of a merchant in the town. They appeared to have been ill since the 16th and 24th of the month respectively. On the 28th a third case occurred in the same house. The house had apparently simply been "cordonned," with sick and healthy together, and this patient developed the pneumonic form of the disease, which rapidly proved fatal.

Plaque in Berrut.

The occurrence of a sporadic case of plague here in July was reported in a former letter. Quite recently three fresh cases have been reported; the first was seen on Nov. 25th. He had then been ill for ten days. The second was seen on Nov. 27th (the eighth day of the attack); the third on Dec. 1st. In the first and third there was bacteriological proof that the disease was plague.

Plague in Alexandretta.

In both Adalia and Beirut plague has been probably endemic, though in sporadic form, for some time past. It has now appeared for the first time in Alexandretta. Two cases were seen there on Nov. 30th; they were the son and daughter of a labourer who had died with suspicious symptoms a fortnight before. At the same time a youth, employed in a store where grain coming from Bombay by way of Alexandria is dealt in, was also found to be suffering from plague. It is added that dead rats had been found in the latter store and in that where the father of the other two patients had worked. These two stores adjoined.

Plague in the Kirghiz Steppes.

In August last the Russian Plague Commission announced officially that several cases of pneumonic plague had occurred in the village of Iltoi, in the district of Ulentin, 140 versts from the town of Uralsk; 22 deaths had occurred, and no further cases were reported after July 31st. This village is obviously in the region of endemic plague described in my letter on this subject which was published in THE LANCET of April 24th last (p. 1197).

Dengue in Syria.

There has recently been a serious epidemic of dengue in Jaffa and in Beirût. Details are wanting, but it is stated that large numbers of people have been attacked in both places.

Constantinople, Dec. 3rd, 1909.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Liverpool Royal Infirmary: Roentgen Ray Installation.

Mr. C. Thurstan Holland, at the Royal Infirmary on Dec. 9th, gave an interesting demonstration with the "Snook" Roentgen apparatus which has been recently fitted up at the infirmary. The X ray department of the hospital in 1905 had 300 patients, and there were now about 3000 cases annually, each ward of the dispensary sending not merely cases where people had been injured by bullets, needles, pins, coins, &c., but cases of the chest, stomach, kidney, and other complaints. Many plates of such cases were shown by Mr. Holland, who said Punch's forecast regarding the little boy who ate overmuch Christmas fare and was subjected to the Roentgen rays had literally come to pass, although at one time it was entertained as a humorous idea. The cost in connexion with the X ray department at the infirmary was seriously increasing, and Mr. Holland mentioned that the hand of bis assistant was permanently injured by the rays, despite the protective measures adopted. Additional accommodation for the X ray department would be afforded when the erection of the new out-patient department had been completed. Mr. Ralph Brocklebank (chairman of the committee of the infirmary), Mr. Holford Harrison (honorary treasurer), Sir James Barr, and others expressed their

appreciation of the lucid demonstration given by Mr. Holland who so ably fills the post of director of the department.

Hospital Saturday Fund.

The Lord Mayor presided at the annual meeting of the Liverpool Hospital Saturday Fund, held on Dec. 7th at the Exchange Station Hotel. There was a considerable and representative gathering. The committee regret that, notwithstanding a strenuous year's work, there was for the first time since the year 1887 a decrease in the receipts for the year. Steadily from £2870 at that time the fund increased, until in 1908 the income was £10,136. Through a combination of circumstances, the principal one being trade depression and its consequent lack of employment, the returns for 1909 only show £8,775, a decrease of £1361. The greatest loss has taken place in the workshop collection. This is attributable to two causes. First, several amounts equal to nearly £90 from special efforts have not been available this year; and secondly, the serious decrease in the subscriptions from contributing firms, especially those where the systematic collection is adopted. The collection has suffered most where the weekly system is in force. Another serious loss has been the 10 per cent. so kindly promised by the guarantors, and which last year realised £433. Since the inauguration of the Fund in 1871 the sum of £179,360 has been collected through the agency of the Hospital Saturday Fund. There are at present 1082 firms assisting the Fund, a considerable number of which only have the annual collection, and the committee again urge the adoption of the weekly system.

Liverpool Medical Institution.

Dr. T. R. Bradshaw, senior physican to the Royal Infirmary and lecturer in clinical medicine at the University of Liverpool, has been nominated by the council of the society as president for the ensuing two years. Dr. Bradshaw has long taken an active interest as a member of the Faculty of Medicine at the University in the education of the medical student. He was the first to draw attention in this country to the significance of albumose in the urine and its association with a special form of bone disease, and gave to the clinical complex the name by which it is generally known in this country—myelopathic albumosuria. He has also been an examiner in medicine at the University of London.

Dec. 13th.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

University Service at the Cathedral.

ON Dec. 7th a special service was held at the Cathedral, by invitation of the Dean, to celebrate the foundation of the University. The members of the corporation attended in state, and together with the University professors and a large number of students made an imposing gathering. The Vice-Chancellor, Pro-Chancellor, and Pro-Vice-Chancellor were also present. The sermon was preached by the Rev. A. A. David, M.A., late headmaster of Clifton College, who has recently been appointed to the headmastership of Rugby.

Testimonial to Professor Lloyd Morgan.

Subscriptions to a testimonial fund for Professor C. Lloyd Morgan are being collected from among those who are concerned with the University, either directly or indirectly. Professor Lloyd Morgan's services to the University of Bristol have not simply been those of an eminent science teacher; he was for many years Principal of University College until the University was born, when he became the first Vice-Chancellor. In both capacities he has striven with the utmost zeal to establish higher education and propagate the University idea in Bristol, and it is felt that the gratitude and admiration evoked by such labours need some outward and visible token such as the testimonial will supply.

The University Colston Society.

The Colston Society's annual dinner has been postponed till either February or March on account of the General Election. It is hoped that on the same day the foundationstone of the new chemical and physiological wing will be laid.

Bristol General Hospital.

The president of the hospital, Mr. Joseph Storrs Fry, has

¹ THE LANCET, July 24th, p. 260.

given £1000 towards the reduction of the existing debt. The Ladies' Needlework Guild held its annual meeting at the hospital last week. The work done by the guild was on view. During the year about 2500 articles, valued at £420, were made, and £35 were subscribed for the purchase of blankets and other things which cannot be made by the guild.

Medical Inspection of School Children in Somerset.

At the last meeting of the Somerset education committee it was decided to appoint another assistant medical inspector at a salary of £250 per annum, with necessary travelling and out-of-pocket expenses. The gentleman appointed will be required to devote the whole of his time to the duties. He will have charge of the Axbridge, Long Ashton, and Wells districts, and he will also render general assistance to the chief medical inspector of schools. Dr. W. G. Savage, the chief medical inspector, reported that for the five months ended October last 8318 inspections of children had been carried out.

The Deconshire County Council and Criminal Lunatics.

At a meeting of the Devon county council held on Dec. 9th a resolution was passed to the effect that:—

This council is of opinion that there should be provided by the Government special asylums to which those convicted of crime and found insane during their period of sentence might be sent, after the expiration of such sentence, should they be found unsuited for a county asylum.

The council decided to send copies of the resolution to the Home Secretary and the County Councils Association.

The Nationalisation of Medical Service.

At the Plymouth Institution on Dec. 9th Mr. Robert Jaques delivered an address on the Nationalisation of Medical Service. There was a good attendance, and Mr. J. Elliot Square presided. Mr. Jaques, in the course of an interesting lecture, made three suggestions: (1) That the Poor-law medical service should be merged in the public health service; (2) the public health service should be national and not a local service, and should be greatly extended; and (3) all voluntary hospitals should be nationalised and all the members of the staff should be paid for their services.

The Royal United Hospital, Bath.

The annual meeting of the Ladies' Working Association of the Royal United Hospital, Bath, was held recently. The report showed that the association numbered 405 members. During the past 12 months 1202 articles of clothing for the patients and linen for the use of the hospital had been distributed.

The Long Fox Lecture.

The sixth Long Fox lecture was delivered on Dec. 14th in the Medical Library of the University by Professor Edward Fawcett, dean of the Faculty of Medicine and professor of anatomy to the University. The pro-Vice-Chancellor, Professor J. Michell Clarke, was in the chair. The subject, the Development of the Human Cranium, though an abstruse one, was lucidly expounded with the aid of many excellent lantern slides and wax models. Professor Fawcett explained the method of preparation of the models, which are built up by projecting serial microscopic sections on a lantern screen of suitable size; from the resulting pictures tracing designs are then cut out of beeswax plates of a known and appropriate thickness. Such models are of value not only for demonstration purposes but also for the elucidation of many doubtful details in embryology.

SCOTLAND.

Dec. 14th.

(FROM OUR OWN CORRESPONDENTS.)

The Proposed Reform of the Medical Curriculum in Edinburgh.

THE medical curriculum at the University of Edinburgh has been discussed and criticised at some length within the past few weeks in the newspaper press of Edinburgh. This has apparently been, in part at least, prompted by a report adopted by the Edinburgh Pathological Club on the curriculum and the general efficiency of the school. The report has been made sufficiently public to account for its being dealt with by the leading local newspaper, for University matters always arouse much public interest, not

only in Edinburgh but in Scotland generally. points in the report referred to will be of interest to many of the readers of THE LANCET as they have more than a local bearing. The report at the outset indicates that as there exists practical coordination between the University and the extra-mural school the deliberations of the committee which was responsible for its final form centred round the University curriculum. It then makes the following general recommendations: (1) It is suggested that students should begin the study of medicine in summer, instead of, as is the more common practice, in winter; (2) that a fixed curriculum should be laid down, so that students should not be allowed to take classes practically in any order they chose; (3) wherever the earlier subjects of the curriculum may studied it is desirable that the later subjects should be studied in Edinburgh; (4) there is a dangerous tendency in medical schools to treat each subject as if it were in a watertight compartment by itself, and this may be obviated by consultation between different departments to arrange for the distribution and coördination of teaching the various subjects; and (5) it is recalled that in the rearrangement of the five years' curriculum the idea in the minds of clinicians was that the strictly scientific subjects would be overtaken in the first two years, and thus the last three years would be given over to the applied sciences and to clinical work. The report then deals with the individual subjects of the curriculum, and these may with advantage be dealt with in the same manner. Botany and roology. These subjects. it is suggested, should be replaced by a short course of systematic and practical instruction in biology. should be extended by the addition of practical instruction to the present theoretical course. These two subjects, biology and physics, might be passed before the winter session began. Chemistry.—The teaching of this subject should be rearranged by cooperation between the departments of chemistry, physiology, and materia medica. By such rearrangement pharmacognosy would form part of the course of descriptive chemistry, while the time now allocated to practical materia medica would be available for organic chemistry, such as would be useful in medicine and would be a preparation for the study of physiological chemistry and of pharmacology. Anatomy.—The study of this subject and the examination in it should be completed before the third winter of study. *Physiology*.—The report practically accepts the views expressed by Professor E. H. Starling at the Sheffield meeting of the British Medical Association, when the subject was discussed by leading physiologists. The report homologates the view that there ought to be a differentiation between physiology as a branch of pure science and as a subject of medical education. Materia Medica. - The two subjects of pharmacology and therapeutics should be treated separately. Pharmacology would be best studied after the examination in anatomy and physiology, and a course of 50 lectures and lecture-demonstrations is suggested. If the rearrangement suggested between chemistry, physiology, and materia medica were effected a course of practical pharmacology would be unnecessary. With regard to therapeutics, it is held that the curriculum should contain a systematised consideration of the subject apart from the treatment it receives in clinical teaching. It is suggested that a course of 50 lectures should be given in the fourth winter. Pathology. Modifications of the teaching of this subject are considered to be necessary. It is suggested that in the third winter. when the student has begun surgery, there should be a course of 50 lectures in general pathology, and concurrently with these a course of 50 meetings for practical pathology, the two courses to form a correlated whole. At a later period there should be a further course in which regional pathology and the pathology of function should be treated of. From these subjects the report passes to the consideration of the "all-important practical subjects of the curriculum -medicine, surgery, and midwifery, and the special branches of these subjects." In Edinburgh the teaching of these three great subjects has long included a systematic treatment in lectures and clinical teaching at the bedside It is recognised that a difference of opinion exists as to the part which systematic lectures should play in the modern curriculum, and the sanction for lectures is given under nive heads—namely, (1) some students derive more benefit from oral instruction than from the reading of text-books: (2) in the earlier subjects where only a knowledge of a small part

¹ See The Lancet, 1908, vol. ii., p. 479.

of a science is necessary it is often difficult to recommend a text-book which will cover the aspect of the subject required; (3) it is fitting that in a great University the individual views of the teachers should have the opportunity of finding expression; (4) in every subject there are general aspects of questions which do not find a place in text-books; and (5) the constant progress of knowledge makes it necessary to present the most recent views on a subject. It is, however, definitely indicated that the systematic lecture should take a less prominent place in the curriculum than it has hitherto taken. The three final subjects are then dealt with seriatim. Surgery.—It is suggested that in the third winter there should be a junior course of 50 lectures on three days a week and a senior course of the same extent in the fifth winter. The other three days a week would be thus available for tutorial work at the corresponding hour. With regard to clinical work, the necessity of insisting upon a definite course of study is again emphasised so that the precise course which each student should pursue should be laid down each term. It is also emphasised that in this way the number of students attending each surgeon should be rigorously limited by the equal distribution of the students to the various teachers. In the teaching, the services of the assistant surgeon attached to each full surgeon ought to be utilised. Importance is given to the out-patient department as a means of familiarising the student with the aspects of surgical practice seen there. Surgery is thus made to occupy a prominent place in the third winter and the following summer. Medicine.—In this subject the ideal course in systematic medicine is given as 90 to 100 lectures in which every system is dealt with generally. With regard to clinical medicine, much stress is, of course, laid upon the great importance of bedside work. It is suggested that the ordinary physicians should be so correlated to the clinical professors that the students would be equally distributed amongst the various teachers. It is also suggested that the assistant physicians ought to take a definite part in teaching. Midwifery and Gynecology.— It is held that oral instruction as pursued in Edinburgh has many advantages, and it is not suggested that it ought to be altered, but that the lectures should be taken in the fourth winter. Special subjects. - These are also dealt with, but as the arrangements for taking them are largely a question of time table and not of principle, they do not require special mention. Attendance, however, on these subjects can only be properly regulated by a definite curriculum being laid down which the student must follow. Examinations. - With regard to examinations, it is suggested that the first pro-fessional subjects should be taken as they are at present. Anatomy and physiology should be passed at the end of the summer after the second winter. At the end of the third winter there should be an examination in pharmacology and elementary pathology, and in medical jurisprudence and public health at the end of the summer after the fourth winter. Another very important suggestion is made-namely, that when a candidate fails twice in a subject he should not be allowed to attend subjects in advance, but must lengthen his curriculum. The question of introducing a block system is referred to, but no strong opinion with regard to it is expressed. Other matters are dealt with in the report, but these have not the same wide interest that belongs to any proposals which have for their object the improvement of the teaching of the student.

Presentation of the Freedom of the City of Edinburgh to Principal Sir William Turner, K.C.B.

On Dec. 10th, on the invitation of the Lord Provost, magistrates, and councillors of the city of Edinburgh, a large number of citizens met in the Synod Hall to witness the conferring of the freedom of the city on Principal Sir William Turner, K.C.B., and the Rev. Principal Whyte, D.D., an eminent local clergyman. The Lord Provost, as is usual on such an occasion, gave a sketch of Sir William Turner's career in Edinburgh, and also sketched the relations past and present which subsisted between the town council and the University. As is also customary on such an occasion the recipient of the honour is expected to make a speech. This Sir William Turner did in his own strong and direct style; he was evidently much affected by having had the honour offered him and by the reception he received. He also referred to the connexion between the University and the University. The event was of peculiar interest as the freedom of the city is not usually bestowed upon citizens. Principal Whyte unfortunately was prevented by indisposition from being present.

Proposal for a New Hospital for Women in Edinburgh.

A meeting was held some days ago in the council chambers, and presided over by the Lord Provost, which had for its object the inauguration of a scheme for a sort of paying hospital for women in Edinburgh, to be officered by men. The scheme met with some criticism at the meeting, and it will be difficult to float any new charity at present; while it would require to be made very clear that it is necessary to add to the medical charities of the city before the proposal would meet with any considerable measure of support from the public or the medical profession.

Appointment.

Dr. A. K. Traill, the medical superintendent of the Sidlaw Sanatorium, Dundee, has received an appointment at the Municipal Sanatorium, Salterley, Birmingham, and has resigned his present appointment.

Poorhouse Medical Officers in Dundec.

At a meeting of the subcommittee of the Dundee parish council it was agreed to recommend for the staffing of the East Poorhouse Hospital a senior medical officer at a salary of £120 per annum, and a junior at £100 per annum. Under this scheme the services of the present medical officers would be continued.

Proposed Infirmary Extension at Dundee.

A scheme for the erection of a large building in connexion with the out-patient department of the Dundee Royal Infirmary was under consideration at a meeting of the management committee on Dec. 9th. The erection will cost between £3000 and £4000, and it is understood that Mr. J. K. Caird, who has frequently come forward to help the infirmary, has promised substantial aid towards the cost. It is proposed that the building shall face Barrack-road, and the matter will come up for further discussion at the quarterly meeting of the governors

Consumption in Turriff.

At a meeting of the Turriff district committee a letter was read, dated Nov. 11th, containing resolutions adopted at a conference on pulmonary phthisis—namely, that notification should be compulsory, that infection should be traced out by officers of the local authority, followed by disinfection where necessary; that hospital accommodation should be provided for cases that could not be treated at home. letter from the town clerk of Turriff was also read suggesting a conference with the town council as to the advisability of extending the present hospital to admit consumptive The feeling of the meeting was in favour of patients. notification and disinfection, but with regard to hospital accommodation there was doubt expressed. Eventually the chairman moved :-

That the district committee approves of the first three resolutions of the conference on pulmonary phthisis, and resolves to make notification of phthisis compulsory in the district and to instruct the sanitary inspector to assist in disinfecting houses where the disease occurs; but while willing to discuss this matter with the town council, is of opinion that a grant should be given by Government for that purpose before any provision for hospital accommodation is made from the rates

The motion was unanimously agreed to, and the matter of meeting the town council remitted to the hospital committee representatives.

Dec. 14th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Irish Universities.

THE following figures give in round numbers the students at present attending the Irish Universities:—National University: (a) University College, Dublin, 90; (b) Ceciliastreet Medical School, 270; (c) University College, Cork, 320; (d) University College, Galway, 120; total, 800. University of Dublin: Trinity College, 1200; Magee College, 90; total, 1290. The Queen's University of Belfast: Faculty of Medicine, 252; Faculty of Arts, 201; Faculty of Science, town council and also spoke of his long connexion with the 1110; Faculty of Law, 12; total, 575. As a result the total

University students at present

University students at present in Ireland are 2665. In Belfast the numbers last session were 456.

Irish Meat-Supplies.

The Local Government Board has just issued a new code of regulations relating to the inspection of all foreign meat imported into this country. The foreign meat trade was very small, indeed, when the old regulations were drawn up, but it has attained considerable dimensions, and it is desired by dealers in the article of home production that the imported meat should be submitted to a process of inspection at least as searching as that which is applied in the case of Irish meat. Of the two varieties of cold-preserved meat which are brought into this country, the "chilled" comes from Liverpool, where it has been slaughtered within the previous 24 hours or less before its arrival at an Irish port; while the frozen comes in many cases from some of the most distant parts of the earth, and may have been killed many months before arrival here. It is hoped that the new regulations for Ireland will provide precautions as careful and effective in the safeguarding of the public meat-supply and the public health as are enforced at the Port of London. It is significant of current opinion that a motion brought before the Limerick county council with the object of discontinuing the attendance of veterinary inspectors at fairs was promptly rejected, and at the annual dinner of the Dublin Victuallers' Association, which took place on the evening before the opening of the Cattle Show of the Royal Dublin Society last week, Mr. T. P. Gill, secretary of the Department of Agriculture, pointed out that the cattle trade of Ireland was being outstripped by other trades not usually considered of so high importance—trade in the produce of the dairy and the poultry-yard and that of bacon. Last year the value of these amounted in round numbers to £9,200,000, while that of the cattle exports made a total of £8,900,000.

Richmond Asylum v. Local Government Board: Report of Judgment.

The joint committee of the Richmond Asylum has published a full report of the judgment which was given in its favour in the Court of King's Bench in the case in which it successfully contested the payment of four surcharges which had been made by the auditor of the Local Government Board. The printed report of the legal details and the circumstances in which they originated (to which I have already drawn attention in this column) is accompanied by an instructive memorandum drawn up by the chairman of the committee (Mr. Richard Jones), who points out that the judgment has established that Irish public bodies are endowed with the right of protection of the interests of the members of the working population by the adoption of the fair wages resolution, and special attention is directed to the passage in which the Lord Chief Baron stated that they should guard to the best of their abilities against the danger of having that clause rendered a dead-letter. Such bodies, in the expenditure of public money, are entitled to exercise the same discretion that the members would use in the conduct of their own private and personal affairs, which includes the power of rejecting the lowest tender when it is thought fit to do so. And He indicates, finally, that it is decided that public bodies are to be allowed to manage, in the real sense of the word, the affairs which were entrusted to them-"that these gentlemen are not appointed to be mere clerks," as the Lord Chief Baron forcibly expressed it. This report will doubtless inaugurate a notable departure in the transaction of public business by the various Irish boards, and the thanks of the Irish public are due to the chairman of the Richmond committee for the preparation of the memorandum, and to this body for the publication of it and the report which it accompanies.

Bangor Hospital, Co. Down.

On Dec. 9th the foundation-stone of the new hospital at Bangor was laid by Miss Connor, who has contributed £500 to the building fund. Situated on an excellent site, this useful cottage hospital will afford accommodation for medical and surgical cases, with rooms for matron and nurses, and with an excellent operating theatre. A simple style of early Georgian architecture has been adopted, carried out in solid red brick with sandstone sills and copings.

The Belfast Branch of the Women's National Health Association.

At the second annual meeting of the Belfast branch of the

Women's National Health Association of Ireland held in the city hall, Belfast, on Dec. 13th, the Right Hon. the Lord Mayor presiding, very gratifying reports were presented from the various subcommittees on the prevention of tuberculosis, the promotion of school hygiene, and the formation of babies' clubs, showing the admirable preventive work that was being done. Among the speakers were the Lord Mayor and Lady Mayoress, the Dowager Marchioness of Dufferin and Ava, the Right Hon. Thomas Sinclair, D.L., Mr. J. S. Bryars (chairman of the Belfast board of guardians), and Dr. W. J. Maguire.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

Honours to Enrico Giglioli.

THE "Republic of Science" is about to show its appreciation of the life and work of this veteran in the field of comparative anatomy and ethnographical exploration by celebrating on Dec. 20th the completion of his fortieth year of professional instruction in the Istituto di Studi Superiori in Florence. Nature students of all nationalities throughout Christendom are taking part in the ceremony and already a lengthy list of names has been received by the secretary of the organising committee (Dr. E. Balducci, Via Romana 19, Florence) in attestation of the universal interest evoked by the anniversary. Among these I may notice the representatives of nature study in the English-speaking world—British, colonial, and American—such as J. T. Cheeseman, Robert Etheridge, Professor A. C. Haddon, Sir E. Ray Lankester, Professor Henry F. Osborn, Charles H. Read, Professor G. D. Thane, Professor E. B. Tylor, Professor Bernhard H. Woodward, and Dr. E. P. Wright. These gentlemen, in compliance with the invitation of the committee, have forwarded to the secretary either their autograph, their carte de visite, or their photograph to be inserted in the album—an artistically illuminated volume in symbolical binding to be presented to Professor Giglioli along with the congratulatory address on Dec. 20th. Other participants in the "testimonial" (for such in a signal sense it is) are in course of doing likewise, thereby giving to the commemoration an "ecumenical" character in keeping with the kinship, or rather the brotherhood, of science. are special reasons for the cordiality with which Englishspeaking nature-students have responded to the appeal. Giglioli is described by his compatriots as "Italo-Inglese, having been born of Italian parents on June 13th, 1845, in London, where, after graduating in medicine at Pisa, he worked with Professor Huxley as a trusted disciple and coadjutor. He made a voyage round the world in the Magenta, and enriched the "Museo di Storia Naturale" in Florence (in which he has long been director of the Gabinetto degli Animali Vertebrati") with specimens, as valuable as they are unique, of zoological treasure-trove. A member of the "Consiglio della Società di Anthropologia," he has laid its transactions under heavy obligations by original research, while his published writings entitled "I original research, while his published writings entitled "I Tasmaniani: Etnologia e Storia di un Popolo Estinto"; "Zoologia della Magenta"; "Relazione del Viaggio intorno al Globo della Pirocorvetta Magenta"; "Iconografia dell' Avifauna Italica"; "Un Bisogno Urgente dell' Antropologia"; "Notizie sul Kalang di Giava"; "Studi Etnologici in Siberia," and many others bear witness to the variety and comprehensiveness of observations distinguished by painstaking accuracy, clear exposition, and charm of style.

Superstition.

"How 'green' is this grey world" (Shelley's memorable line) might have been the motto of Professor Pio Foà's recent lecture before a popular assembly at Milan on "Pregiudizi e Vittorie di Medicina." Superstition playing into the hands of charlatanism dates from remote antiquity and finds illustration even in what the platform declaimer referred to as "this so-called twentieth century." A generation which has witnessed the pathological and therapeutic triumphs of Virchow, Pasteur, Lister, Koch, Behring, and Schaudinn is still capable of such tragedies in "faith-healing" as that reported from the quondam states of the Church, where a poor peasant woman, bitten by a mad dog, was dissuaded from using the money subscribed to take her to the

"Istituto Antirabbico" in Rome and prevailed upon to dedicate it, with prayer, to the local Madonna, whose "saving grace" (she was assured) was worth all the medical treatment in the world. As a result of this advice she died in what the newspaper records as "dolori strazianti" (excruciating pain)—her money gift and fervent prayer notwithstanding. "Ignorance," in Loyola's phrase, "may be the mother of devotion." But it is also the parent of misery and suffering preparable exceptible in a country where the and suffering unspeakable, especially in a country where the "analfabeti" (unlettered) number more than one-third of the population.

A True Sister of Meroy.

Miss Alice Burke, whose many gifts, including a rare sagacité de cœur, were for 20 years devoted to the ailing and the injured in the Hospital of Santa Catarina in Florence, died on Nov. 23rd, at her residence in the Tuscan capital. The tragic fate of Mr. Thomas Burke, Under-Secretary to the Irish Viceroy—assassinated in the Phoenix Park, May 6th, 1882, in company with Lord Frederick Cavendish, who tried to save him—not only cost her a dear brother's life, but profoundly affected her own. Associated with him in his office and home in Dublin Castle, she left her native Ireland never to return, and for the last 22 years found distraction and solace in Italy, devoting to fine art, particularly painting, such time as she could spare from the self-imposed duties of the hospital. In water-colours she reproduced the chef-d'œuvres of the old masters with a fidelity and power that attracted many artists, Italian and others, to the studio, while her salon was the congenial resort not only of these but of other guests distinguished in science, literature, and affairs.

A niece of Cardinal Wiseman, and sharing much of his conversational charm in four languages, she drew around her all that was most distinguished in Florentine society, resident or migratory, enlisting their sympathies, moreover, in her numerous charities, among which was her relief work in behalf of the survivors of the Siculo-Calabrian cataclysm. This, the last of her more conspicuous efforts in the philanthropic sphere, told heavily on a constitution naturally strong and elastic, but impaired by profound if nobly suppressed grief and by strenuous devotion to the religious life; and so the malady, which she had long struggled against in secret, after months of suffering at last prevailed. Her funeral was attended by numbers of the Florentine poor, for whom her grave at San Miniato, where, beside her artist brother Augustus, she sleeps under a Celtic cross of her own designing, will long be a "point of pious pilgrimage."

Small-pox in Italy.

The Association for Promoting the Influx of the Outlying World into Italy will do well to use its undoubted influence with the central authorities so as to mitigate, if not remove, one at least of the far too numerous deterrents to the "influx" in question—to wit, the steady spread of small-pox throughout the kingdom. The correspondence columns of THE LANCET have drawn attention to the epidemics of the disease at Parma, at various points on the Milan-Domodossolo line, and more recently at Salerno-all these, be it noted, occurring within a few weeks of each other and all of them implying culpable negligence in vaccination. But as if the admonition were unavailing, one of the leading journals of Italy, the Secolo, alarms its readers this morning with the announcement of "Smallpox at the Gates of Milan," and proceeds to give authentic details of the number of cases, the number of deaths, and the frantic efforts, promoted from the Lombard capital, to undo the disastrous results of communal "trascuranza" (negligence), first, in prevention, and second, in treatment. Take, for instance, the following typical specimen of the modus operandi (or rather the modus negligandi!) brought home to the "bureaucratic authorities" within less than four miles of the most prosperous of Italian cities. At that distance from Milan there is the township of Turro, which, two years ago, numbered 593 souls, and which has recently added to its population-mainly by fugitives from Milan unable to meet the cost of house rent and food—some 10,000 more, huddled together in old, or insufficient new, tenements, and living under conditions compatible only with misery and disease. Two years ago the school counted 50 pupils, now there are 700, without proportionate addition to the accommodation—a state of things, perhaps, intelligible when, according to the Secolo,

the finances of the commune are verging on bankruptcy, with a debt of some 20,000 francs and with only some hundreds in the cassa to meet it. Add to this that Turro is the refuge of the malandrini (malefactors) who have made Milan too hot to hold them-"undesirables' import not only vice and crime, but actual disease, living as they do beyond the pale of law and administrative surveillance. Small-pox in such a population will spread in proportion as vaccination has been either neglected altogether or perfunctorily applied. Nor is Turro the only neighbour from which the Lombard capital is threatened. Lodi and its vicinity-according to the Secolo-are also suffering from the same visitant. Here, again, as at Turro, the efforts at isolation, disinfection, and revaccination are put forth with febrile energy, in tardy replacement of the measures which, taken in time and with due care, would have kept the disease at bay. All this is unpleasant reading for the Italian and the non-Italian world alike—spelling for the former the loss of that "foreign import" (as it terms the "paying guest" from abroad) to which it owes one-third of its revenue; and for the latter the loss of that sojourn in the winter and the spring season to which it looks for health and vigour during the remainder of the year. The winter now upon us is one, which from various causes, can ill brook the gratuitous deterrent of small-pox. The "arrivals," hitherto, have been below the average in all the chief towns of Italy a fact for which the General Election shortly to be held in the British Isles is partly responsible. Other causes are mentioned as conducing to the same "falling off"-anticipated reduction of income and the prospect of enforced economies, ascribed (rightly or wrongly) to recent fiscal legislation, being among them. The situation, indeed, is one which Italy, in her own interests, cannot ignore, fraught as it is with loss to her from within and from without, and only to be retrieved, on her part, by systematic and steady enforcement of her "Codice Igienico," which, admirable as it is "on paper," has hitherto been but sparingly utilised in practice. Dec. 6th.

VIENNA. (FROM OUR OWN CORRESPONDENT.)

The Annual Meeting of the Austrian Medical Councils.

THE continual difficulties which the medical profession has to encounter in this country in regard to its organisation and the furtherance of its lawful requirements have led the Aerztekammern, or Medical Councils, composed of the representatives of the profession in all parts of the country, to hold an annual meeting for the discussion of important questions. Such an annual meeting is called the Aerztekammertag, and the one for the present year was held at Vienna during two days in the end of November. One of the subjects was that of insurance against various risks. A company for insurance against accidents and also for life insurance has been called into existence by medical men, and a special point of this company will be insurance against charges of malpractice. Claims against medical men on the ground of malpractice have increased to such a degree as to become a serious danger, for although nearly all the cases brought into court are dismissed, the expenses incurred by practitioners in their defence are nevertheless very heavy. Much time was devoted to the discussion of the proposed Socialversicherung (general insurance against sickness) by the Government. As the friendly societies and the obligatory sick-clubs try to obtain as many members as possible, claiming eligibility for all persons who earn their living by employment, only patients who are of independent means would be left for private practitioners. In this country the majority of medical men would be ruined if this view were adopted by the Legislature. This proposed insurance against sickness is embodied in a Bill promoted by the Government and is intended to relieve the working-class in times of difficulty, especially during illness of the bread-winner. Now the political parties and also the section of the population mostly concerned have proposed that every person earning less than 4800 kronen (£200) a year shall come within the scope of the law-i.e., should

attendance and daily sick-pay, the medical officers being appointed by the clubs. These provident institutions are very beneficial to their members, but, on the other hand, they have a disastrous effect on medical practice, because for a salary varying from £100 to £200 a year, and never exceeding the latter amount, the medical officer of the Kassa has to attend at least 1000, but more generally from 3000 to 5000 persons all the year round. In these circumstances, private practice in the ordinary sense is hardly possible. The medical profession, on the other hand, wishes to limit the income which carries with it compulsory membership of a Kassa to 2400 kronen (£100) a year. The statistics compiled by the Surveyor of Taxes for 1907 show that in Vienna alone there were 73,000 wage-earners who had returned their annual incomes as being between 2400 and 4800 kronen. If this Bill becomes law these persons and their families would be lost as possible private patients for the general practitioners who did not happen to hold club appointments. On the other hand, it is impossible in Austria to bring about an organisation of medical men which would be in a position to dictate terms to the Krankenkassen. In the discussion it was shown that in this country there are about 2000 medical men which the state of the country that is the state of the sta medical men who are not earning enough to live upon, and they would be the first to suffer if the Bill should be passed, as then their income would be cut off entirely. Another point much discussed was the Bill dealing with a modification of the existing Health Act. A resolution was passed in which the meeting expressed strong disapproval of the modification, because it was drafted without asking the opinion of the Aerztekammern, and was, moreover, inconsistent with the interests of the medical profession. The chief points of controversy were the definition of the posi-tion of the practitioner relatively to the officer of health, payment for notification of infectious diseases, the method of taxing medical incomes, and the right of private practice by holders of State appointments. The law dealing with quackery was also an item on the programme of the discussion. In Austria the law is not satisfactory on this point, and "nature-healing" is in great favour among certain classes of the population. The following resolution was adopted by the meeting and recommended to the Ministry of Justice as suitable for a satisfactory basis:

Whosoever undertakes, without possessing a regular Austrian diploma of M.D. or a recognised equivalent diploma of a foreign university, the medical treatment of any person or persons with or without payment or fee shall be guilty of a breach of the law. Nevertheless, when an imminent danger is threatening the life of the affected person, a non-qualified person may interfere in a medical sense. The punishment of such a breach of the law shall not be less than one month and not more than three months' imprisonment for each offence.

The position of the practitioner towards his patient was also a subject of discussion. The existing law does not provide any special privilege or immunity for a medical man in reference to any particular form of treatment. a short time ago operative interference was regarded as quite justifiable if the practitioner thought it necessary, but in several recent instances the Chief Court of Austria has decided that an operation, or an extension of an operation, performed without the special (and perhaps even the written) consent of the patient may form the basis of a claim for damages against the surgeon. In certain circumstances the law requires a medical man to break some statute, such, for instance, as that relative to professional secrecy. An example of this kind was mentioned in this column on June 19th. The meeting decided to present a petition to Parliament praying that the Bill may be modified so that legitimate professional work shall not bring a practitioner into conflict with the law. Some important questions were raised in connexion with the title of specialists. A movement is on foot in this country to regulate the assumption of medical titles and to permit only actual holders of university titles to use them in their scientific publications and on their door-plates. On the same principle, consulting physicians. privat-docenten, and professors would be required to confine themselves to consulting practice, and no practitioner would call himself or allow himself to be called a specialist unless he practised only in his special branch and could prove that he has had special training in this branch for at least a year at a recognised clinic or hospital. Local requirements should be considered in the instances where a combination of two or more special branches of medical practice in one practitioner were necessary. Naturally, there was a certain amount of opposition

manifested against all these proposals, especially against the last-named one; but still, the proceedings of the Aerztekammertag showed that much good work could and would be done by these meetings; and already the power of this organisation of medical corporations is making itself felt by the newspapers which champion the cause of the Krankenkassa, for the medical profession in general is obviously dissatisfied with the salaries and other conditions offered by the sick-clubs.

Dec. 13th.

Gbituary.

WILLIAM BRAMWELL RANSOM, M.A. CANTAB., M.D., B.Sc. Lond., F.R.C.P. Lond.,

SENIOR PHYSICIAN TO THE NOTTINGHAM GENERAL HOSPITAL;
PHYSICIAN TO THE SHERWOOD FOREST SANATORIUM
FOR CONSUMPTION, ETC.

THE name of Ransom, held by father and son, is not only a household word in Nottingham, but is widely known in the medical world outside that city. Dr. William Bramwell Ransom, the subject of this memoir, commenced practice in the city of his birth in 1890, and shortly afterwards was appointed physician to the Nottingham General Hospital on the resignation of his father. Only two and a half years have elapsed since Dr. W. H. Ransom, F.R.S., passed away full of years and honours, and now on Dec. 9th his no less gifted son has been called from his unfinished work at the untimely age of 48 years, deeply mourned by a large circle of friends and patients.

Educated in the most liberal manner for the high calling he was destined to pursue, Dr. Ransom already manifested in his boyhood and as a scholar at Cheltenham College those gifts, so conspicuous in after life, which education can but foster and cannot create. From Cheltenham at the age of 17 he went as a student, as his father had done before him, to University College, London. In 1882, being now 21, he headed the list in physiology honours at the Final B.Sc. Lond., carrying off the University scholarship and medal. He had already in 1880 entered at Trinity College, Cambridge, and in 1883 graduated as a B.A., taking first-class honours in the natural science tripos. On account of his great interest in physiology he was sent by the University to do original work at the Zoological Station at Naples, and at a similar institution at Roscoff in Brittany. As a result of this work he published articles on "The Cardiac Rhythm of Invertebrata," "The Influence of Glycerine on the Liver" (Journal of Physiology, Vols. V. and VII.), "The Spinal and Visceral Nerves of Cyclostomata," and other papers well known to physiologists.

In 1886 he was elected Fellow of Trinity College, Cambridge, among the highest distinctions to be obtained at the University of Cambridge, and certainly one of the most difficult to get. Having returned to University College, London, to study medicine, he gained two Fellowes medals for clinical medicine, the Liston medal for pathology, and graduated M.B. Lond. in 1888. After a year's post-graduate study in London, Vienna, and Halle, he took the M.D. in 1889. In the following year he became a Member of the Royal College of Physicians of London, and the same College recognised his excellent abilities by electing him to the Fellowship in 1898. No sooner had Ransom settled in Nottingham than it was felt, not only among the medical profession, but by everyone with whom he came in contact, that a new power had arisen in the place. On the boards of charities and other committees he at once showed an insight into difficult problems which astonished men of more years Whenever he spoke he was attentively and experience. listened to, and his weighty words were always delivered with grace and ease of style, and not without drawing upon a fund of real humour. In these circumstances it cannot be wondered at that his consultant practice in the city and county spread rapidly. He early recognised that purely medical practices could not be expected to be as large as formerly, on account of the ever-increasing developments of surgery and of specialism, but his own limitations were wide, for he was always an exceedingly busy and even an over-worked man. He was popular alike with patients and practitioners; to the former he was invariably kind and sympathetic, and to the latter courteous and very

His admirable memory and reasoning powers sometimes made the diagnosis of a case which had appeared difficult to others a matter of instinct, yet he had none of the arrogance of intellect. He must have seen something of the mistakes of others, yet he never did or said anything calculated to disturb the relations of doctor and patient. "I never wish to meet a nicer or a fairer man in consultation "-this is not a mere commonplace of nil nisi honum type, but has been said of Ransom scores of times during his life.

Shortly after he commenced practice Dr. Koch announced the discovery of tuberculin. Ransom's untiring energy was shown by his making a special journey to Berlin to obtain at first hand a supply of the new specific. Its effects were afterwards demonstrated to the medical profession in the wards of the General Hospital by himself and his colleagues. For 17 years, until finally struck down by illness, he was the constant and devoted servant of that institution. For years he spent the whole of his Sunday mornings in the wards, besides numerous visits on week-days. Add to this five or more long hours for out-patients on Friday afternoons, and some conception can be formed of the work he forced himself to do, instead of allowing some space for rest and recreation. He never had a strong physique, and the enormous amount which he got through was a continual triumph of mind over matter. He was not only keen in acquiring but generous in imparting knowledge. On those Sunday morning visits he was frequently accompanied by a small but earnest band of men to whom he expounded his science with ungrudging patience, while for years he lectured to nurses with an earnestness which others keep for academic addresses. No matter what the occasion, he always gave of his best—Nit tetigit quod non ornavit. His relations with his honorary colleagues and with the resident medical and nursing staffs were always of the most cordial description. In addition to the General Hospital he was also a member of the honorary staff of the Nottingham and Notts Convalescent Homes, to which institution he rendered valuable service by advising on medical, hygienic, and administrative matters.

In 1892, when the British Medical Association met in Nottingham, W. B. Ransom was secretary of the Section of Medicine, his father being President. He also took part in the Leicester meeting in 1905. The British Association for the Advancement of Science met in Nottingham in 1893, Ransom being one of the secretaries. He was a governor of the Nottingham High School and a member of the council of the Nottingham University College. He was President of the Nottingham Medico-Chirurgical Society during the session 1896-97, and on that occasion delivered a masterly address on "Immunity to Disease," which was published in full in THE LANCET. He was a frequent contributor of valuable clinical and pathological material to this society. Year after year he delivered set addresses, and however long these might be he possessed the happy art of keeping his audience interested to the end. No matter what the subject—"Should Milk be Boiled?"; "The Prevention of Tuberculosis"; "Pernicious Anæmia"; "Experiments on Animals"; "Infantilism"; "Modern Views on the Nervous System"; and many more—all were treated in the same exhaustive manner, it being a wonder to all how he obtained his knowledge. When he opened a discussion on Diet on Dec. 5th, 1906, there seemed to be no diminution in the familiar energy of manner or depth and facility of treatment. Yet that was the last occasion on which his voice was to be heard within the four walls so often the silent witnesses of his eloquence.

Ransom threw-himself heart and soul into the question of the open-air treatment of phthisis, which began to be strongly advocated in Great Britain about the year 1898. By his untiring labours and great enthusiasm a society for the prevention of consumption was formed. A lasting monument to those labours remains in the form of the Sherwood Forest Sanatorium. By his own generous and self-sacrificing efforts a building fund of over £5000 was collected, a site having been provided by the munificence of the Duke of Portland. It is no easy matter in these days to start a new medical charity, and it is not too much to say that this sanatorium owes its existence to the unstinted efforts of Ransom in arousing the necessary enthusiasm. He possessed a unique combination of gifts which alone could make such an

patients, all of the poorer class. This beneficent work has been brought within reach of an ever increasing number of patients, 32 of whom are now accommodated in the sanatorium.

Ransom contributed a number of articles to medical literature, many being of permanent value, in addition to those already referred to. Among these the following may be mentioned: "A Case of Actinomycosis" (Transactions of the Royal Medical and Chirurgical Society, 1892); "Some Cases of Cerebral Disease" (THE LANCET, 1893); "A Case of Actinomycosis of the Orbit, with a Summary of Seven Other Cases of Actinomycosis" (British Medical Journal, 1896); "A Case of 'Intestinal Sand'" (Quarterly Medical Journai, 1892); "Two Cases of Acromegaly" (British Medical Journal, 1895); "Immunity to Disease" (THE LANCET, 1896); "Case of Tumour of the Spinal Dura Mater" (British Medical Journal, 1894); "Syringomyelia" (Journal of Pathology, Vol. XI.); "A Case illustrating Kinæsthesis" (Brain, 1892); "Tumours of the Corpus Callosum" (Brain, 1895); "Phthisis in Relation to Life Insurance" (1900); "The Medical Man as Expert" (THE LANCET, 1905); "Plumbish from Investions of Disabellar as Expert" (Gibb. from Ingestion of Diachylon as an Abortifacient" (with Dr. Arthur Hall, THE LANCET, 1906); "The Vis Medicatrix (presidential address, Nottingham Naturalists' This is by no means a complete list of his Society). published writings, but it will serve to illustrate his indefatigable industry and the wide range and many-sided interest of his observations. By a strange irony of fate Dr. Ransom fell a victim to the disease—consumption which he had done so much to relieve. During the later years of his life he contracted several severe attacks of influenza. Definite symptoms of phthisis showed themselves in the summer of 1907 and the disease proved fatal about two and a quarter years later.

He married in 1898 a daughter of Mr. George Fowler of Basford Hall. She and their three children survive him.

Dr. Henry Head writes: "I first knew William Bramwell Ransom in the year 1880 when we entered together at Trinity College, Cambridge. He had already received a considerable scientific training at University College, London, where he attended Professor Lankester's lectures. He was intensely enthusiastic for both comparative anatomy and physiology, and at the end of his first year became a major scholar of his college. After taking his degree with first-class honours in the second part of the Natural Science Tripos (1883), he went to Naples and worked at the action of the heart in the cuttle-fish and other allied animals. On this work he obtained a Fellowship at Trinity College, and then entered strenuously on his medical studies at University College Hospital. Here he held all the ordinary junior appointments and was house physician to Dr. Ringer. He returned to Nottingham about the year 1890, and the rest of his career is better known to others than to me. In his earlier days he was always known to us for his vivacity and for the agility of his intellect. In our debates, whether in the laboratory, the hospital, or the natural science club, he was distinguished for the extraordinary accuracy of his knowledge over an unusually wide range. He had been brought up in an atmosphere of natural history and had been taught by his father to observe the phenomena of nature. To this had been added a superb zoological training which gave him an unusually wide range for so young a man. His power of interesting himself in new medical subjects was the outcome of his agile mind, and I know no man who could put forward so luminous and accurate an account of some recent advance in medicine in which he had interested himself. Unfortunately the last years of his life were haunted by perpetual ill-health which lowered his vitality and made the work that he had previously loved a heavy tax on his failing strength."

GEORGE FREDERICK BERGIN, M.B. LOND., L.R.C.P. LOND., M.R.C.S. ENG.

Dr. G. F. Bergin, who died at his residence, 1, York Buildings, Clifton, on Dec. 7th, in his forty-fifth year, was the eldest son of Mr. G. F. Bergin, the honorary director of Müller's He received his medical education Orphanages, Bristol. at the Bristol Medical School, where he obtained the Martyn and also the Sanders Scholarships. Dr. Bergin also studied at Guy's Hospital. Hequalified L.R. C. P. Lond, and M.R.C.S. Eng. in 1889, and graduated M.B. of the University of London in 1893. After holding some resident appointments at the effort successful. The sanatorium was opened for 14 Bristol General Hospital Dr. Bergin decided to go to China as a medical missionary. He contracted malarial fever there, and, Bright's disease following, his health was completely broken, and he returned home about ten years ago. Dr. Bergin was afterwards strong enough to take part in the work at Müller's Orphanages, and his tact and judgment were most useful in the management of this large institution. Dr. Bergin was highly respected and his early death is much regretted. The funeral, which took place on Dec. 10th at Arno's Vale Cemetery, Bristol, was very largely attended.

MARK FARRANT, L.R.C.P. LOND., M.R.C.S. ENG., D.P.H.

Mr. Mark Farrant died at his residence in Exeter on Nov. 28th in his thirty-ninth year. He received his medical education at the Westminster Hospital, and qualified L.R.C.P. Lond. and M.R.C.S. Eng. in 1893. Mr. Farrant joined his uncle in practice at Exeter, and in 1896 was elected medical officer of health for the St. Thomas rural district. Mr. Farrant was also medical officer and public vaccinator for the St. Thomas district of the St. Thomas (Exeter) board of guardians, but had resigned his appointments some months ago owing to failing health. He was very popular in Exeter and took a great deal of interest in the political life of the "ever faithful city.'

ROYAL SOCIETY OF MEDICINE: A SPECIAL MEETING OF THE FELLOWS; THE ANNUAL DINNER.

A LARGELY attended meeting of the Fellows of the Royal Society of Medicine was held at Hanover-square on Dec. 15th to discuss an important scheme which had been brought forward by the Council of the Society, on the recommendation of the House and Finance Committee, with the object of raising £60,000 to enable the society to build a new home for itself. The particular scheme put forward was rejected by a large majority, but the result of the meeting was to show an absolute consensus of opinion that the Royal Society of Medicine was inadequately housed and ought to take steps at an early date to remedy the position. Although the meeting rejected the scheme put forward by the House and Finance Committee, the pains at which that committee had been to arrive at a solution of some great practical difficulties were recognised, and the thanks of the society were expressed to them, and especially to Dr. Arthur Latham for the very large amount of time and trouble expended in considering the matter.

The annual dinner of the society was held in the evening at the Hotel Cecil, Strand, Sir William Church, President of the Society, being in the chair. Nearly 200 sat down, and the guests included Lord Strathcona; Sir Archibald Geikie, President of the Royal Society; Sir R. Douglas Powell, President of the Royal College of Physicians of London; Mr. Butlin, President of the Royal College of Surgeons of England; Dr. James Porter, Medical Director-General of the Naval Medical Service; Lieutenant-Colonel Sir Arthur Keogh, retired Director-General of the Army Medical Staff; Dr. P. W. Latham; Mr. A. W. Aston, Master of the Skinners' Company; General Sir Lionel Spencer; Dr. Macnaughton Jones; Dr. Samuel West, President of the Medical Society of London; and Dr. Squire Sprigge, Editor of THE LANCET.

The toast of "The Royal Society of Medicine" was given by Sir Archibald Geikie, who in sympathetic terms congratulated the Society on its success in gathering together so many different constituents under one roof, and admitted that the time might soon come when the Royal Society itself would have to adopt some such amalgamation scheme.

Sir WILLIAM CHURCH, in replying, referred to the scientific work of the society during the year as being eminently satisfactory, the discussion on Heredity held having been especially important. The library had been attended by 8564 readers during the year, and nearly 8000 books had been borrowed from the library. The society now numbered 2328 Fellows and 991 Members. The expenses of publication were very great, however, and he suggested that the reports of the proceedings of the society might often be curtailed with advantage.

Dr. NORMAN MOORE proposed the health of the guests "in historical sequence," alluding in a speech full of bright

and happy allusions first to Lord Strathcona's position as a Privy Councillor, or member of the Magnum Concilium which existed before Kings, Lords, or Commons were instituted; next to Mr. Aston, as representative of the ancient City of London; next to Dr. James Porter and Sir Alfred Keogh, representing services that had their origin before the days of the Normans, "when most things seem to have begun"; and then to the Royal Colleges; and to THE LANCET, concerning the breadth of whose interests he told a flattering story.

Mr. Butlin, in responding, said he hoped that the Royal Society of Medicine would have a home worthy of its great position to show to the distinguished strangers who will visit London at the next International Congress of Medicine.

After Sir RICHARD DOUGLAS POWELL had proposed the toast of "The Chairman," Sir WILLIAM CHURCH, in reply, said that already a building fund had been started.

Medical Rews.

ROYAL COLLEGE OF SURGEONS OF ENGLAND .-At the Final Examination for the Fellowship in Surgery, Surgical Anatomy, and Pathology, held on Nov. 22nd, 25th, 26th, 27th, 29th, and 30th, 1909, 72 candidates presented themselves, of whom 30 were approved and 42 were rejected. Among the successful candidates were two gentlemen (John Henry Farbstein, M.B., B.S. Lond., L.R.C.P., M.R.C.S., University College Hospital, and Shamrao Ramrao Moolgaokar, L.R.C.P., M.R.C.S, Bombay University and King's College Hospital) who have not yet attained the requisite age of 25 years. The Council accordingly conferred the Diploma of Fellow upon the 28 gentlemen mentioned below. who have complied with the necessary by-laws:

Diploma of Fellow upon the 28 gentlemen mentioned below, who have complied with the necessary by-laws:—

John William Geary Grant, L.R.C.P., M.R.C.S., St. Thomas's Hospital: David Leighton Davies, M.D., M.S. Lond., L.R.C.P., M.R.C.S., University College Hospital; Hugh BernardWilloughby Smith, M.B. Lond., L.R.C.P., M.R.C.S., London Hospital; William Square Edmond, L.R.C.P., M.R.C.S., St. Bartholomew's Hospital; Walter Goldle Howarth, M.B., B.C. Cantab., L.R.C.P., M.R.C.S., Cambridge University and St. Thomas's Hospital; Arthur Donald Griffith, M.B., B.S. Lond., L.R.C.P., M.R.C.S., King's College Hospital; Francis Rudolph Hotop, M.B., B.Ch. New Zealand, L.R.C.P., M.R.C.S., New Zealand University and King's College Hospital; Arthur Sydney Blundell Bankart, B.C. Cantab., L.R.C.P., M.R.C.S., Cambridge University and St. Bartholomew's Hospital; Henry Sessions Souttar, M.A., M.B., B.S. Lond., L.R.C.P., M.R.C.S., Cambridge University and St. Bartholomew's Hospital; Henry Sessions Souttar, M.A., M.B., B.Ch. Oxon, L.R.C.P., M.R.C.S., Cambridge University and St. Thomas's Hospital; Walter Rowley Bristow, M.B., B.S. Lond., L.R.C.P., M.R.C.S., Cambridge University and St. Thomas's Hospital; Walter Rowley Bristow, M.B., B.S. Lond., L.R.C.P., M.R.C.S., St. Thomas's Hospital; Rustom Nusserwan Coorlawala, L.M. & S. Hyderabad, D.P.H. Cantab., L.R.C.P., M.R.C.S., University College Hospital; Ardeshir Pestonji Bacha, L.M. & S. Bombay, M.B., B.S. Lond., L.R.C.P., M.R.C.S., University College Hospital; Ardeshir Pestonji Bacha, L.M. & S. Bombay, M.B., B.S. Lond., L.R.C.P., M.R.C.S., Bombay University and University College Hospital; Rustom Manchersha Dhanjibhai Dorabji Gilder, M.B., B.S. Lond., L.R.C.P., M.R.C.S., Bombay University and London Hospital; Wilfrid Warwick Treves, B.A., B.C. Cantab., L.R.C.P., M.R.C.S., Bombay University and London Hospital; Alfred Gough, M.B., Ch.B. Glasg., Glasgow University and London Hospital; Hubert Gordon Thompson. M.D., Ch. B. Liverp., Liverpool University and London Hospital; Hubert Gordon Thompso

Licences to practise dentistry were also conferred upon the following 36 gentlemen, who have passed the necessary examinations and complied with the by-laws:

xaminations and complied with the by-laws:

Richard Guy Ash, Charing Cross and Royal Dental Hospitals; Reginald John Bailey, Middlesex and Royal Dental Hospitals; Guy Capper Birt, St. Thomas's and Royal Dental Hospitals; Charles Rrnest Blows, Charing Cross and Royal Dental Hospitals; Cecil Hastings Bradnam, Guy's Hospital; Harry Fielden Briggs, M.D. L.A.H., L.D.S. Glasgow, D.D.S. Michigan, Michigan and Bristol Universities: Charles Rdward Brown, Liverpool University; Frank Bocquet Bull, Guy's Hospital; Eric Horsfall Chesters, Birmingham University; Leonard Dinnis, Charing Cross and Royal Dental Hospitals; Lionel David Frühauf, Charing Cross and Royal Dental Hospitals; Lionel David Frühauf, Charing Cross and Royal Dental Hospitals; John Daniel George, Guy's Hospital; Bernard Goldsmith, Middlesex

and National Dental Hospitals; Arthur Rusby Hawksley, Liverpool University; George Theodore Douglas Hughes, Liverpool University; Percy Stanley Humm, Guy's Hospital; Leonard John Kemp, Guy's Hospital; William Caffyn Miller, Guy's Hospital; Cecil Graves Morris, Guy's Hospital; Walter Cecil Murray, Charing Cross and Royal Dental Hospitals; James Ormrod, Liverpool University; Percy Hills Orton, Guy's Hospital; Alfred Bunce Plank, Liverpool University; John Morley Pomeroy, Guy's Hospital; Reginald Wood Powell, Guy's Hospital; Arthur Pusey, Middlesex and National Dental Hospitals; George Hubert Walter Randell, Middlesex and National Dental Hospitals; John Roberts, Guy's Hospital; Bertram Charles Salter, Charing Cross and Royal Dental Hospitals; John Henry Skerritt, Sneffield University; Theodore Victor Smith, D.D.S. Penn., Pennsylvania University and Charing Cross Hospital; Stanley Runton Storey, Charing Cross and Royal Dental Hospitals; Norman Healea Swallow, Manchester University; Herbert Thornton, Guy's Hospital; and Henry Alfred Woodhouse, M.A. Oxon., Middlesex and Royal Dental Hospitals.

University of Oxford.—The following candidates have been approved in the undermentioned examinations :-

FIRST B.M. EXAMINATION.

FIRST B.M. EXAMINATION.

Organic Chemistry.—H. E. A. Boldero, Trinity College; C. H. Carlton, St. John's College; F. B. Chavasse and W. T. Collier, Balliol College; L. M. Davies, Lincoln College; J. C. Dixey, Brasenose College; K. M. Dyott, non-collegiate; V. T. Ellwood, Pembroke College; L. Gameson, Queen's College; O. H. Gotch, New College; W. J. Hart, B.A., Queen's College; J. W. Horan, Brasenose College; M. R. Lawrence, B.A., St. John's College; P. A. Martin, New College; T. S. Nelson, University College; A. L. Pearce-Gould, B.A., Christ Church; E. Scott, B.A., St. John's College; G. P. Selby, New College; N. A. Sprott, Christ Church; and C. P. Symonds, New College; N. A. Sprott, Christ Church; and C. P. Symonds, New College; A. Booth, B.A., Keble College; A. Jackson, Queen's College; A. Booth, B.A., Keble College; A. Jackson, Queen's College; H. M. Pope, B.A., Lincoln College; M. O. Raven, Trinity College; and J. Sainsbury, Oriel College.

Second B.M. Examination.

SECOND B.M. EXAMINATION.

SECOND B.M. EXAMINATION.

Pathology.—G. E. Downs, B.A., Magdalen College; A. D. Gardner, B.A., University College; G. W. Johnson, B.A., Brasenose College; C. Newcomb, B.A., St. John's College; E. L. Pearce-Gould, B.A., Christ Church; and A. F. S. Sladden, B.A., Jesus College.

Forensic Medicine and Public Health.—R. F. Bridges, B.A., University College; G. H. Hunt, B.A., Christ Church; S. F. Moore, B.A., Trintty College; H. P. Newsholme, B.A., Balliol College; and A. F. S. Sladden, B.A., Jesus College.

Medicine, Nurgery, Midnifery.—F. J. Aldridge, B.A., Magdalen College; H. G. Butterfield, B.A., Wadham College; G. H. Cross, B.A., Balliol College; D. C. Dobell, B.A., Christ Church; G. J.Z. Jessel, B.A., University College; S. F. Moore, B.A., Trinity College; C. Newcomb, B.A., St. John's College; and H. P. Newsholme, B.A., Balliol College.

MEDICAL CONGRESS.—An AMERICAN International Congress of Medicine and Hygiene is arranged to be held at Buenos Ayres in 1910. The opening day is May 25th.

Dr. Mosny has been elected a member of the Academy of Medicine of Paris. The candidates who were placed second and third on the list, but a long way behind Dr. Mosny, were M. Lemoine and M. Vallon.

THE SEWERAGE OF OKEHAMPTON (DEVON).—A Local Government inquiry was held last week at Okehampton in reference to the application of the local town council for sanction to borrow £4300 for sewerage and sewage disposal works.

PLAGUE IN INDIA.—In all India during the week ending Nov. 6th there were 5725 cases of plague, resulting in 4479 deaths. The deaths in the provinces were as follows: Bombay, 850; Madras, 104; Bengal, 89; United Provinces, 918; Punjab, 697; Burma, 19; and Central Provinces, 950. The mortality in the preceding week was 3456.

SANITARY INSPECTORS UNDER PUBLIC HEALTH (LONDON) ACT, 1891.—Examinations recognised by the Local Government Board under the above Act will be held at the Examination Hall, Victoria Embankment, London, W.C., commencing Tuesday, Jan. 18th, 1910. For particulars application should be make to the Honorary Secretary, The Sanitary Inspectors Examination Board, 1, Adelaide Buildings, London Bridge, London, E.C.

University of Cambridge.—The special board for biology and geology has appointed Mr. A. E. Shipley, M.A., Christ's, to be a manager of the Balfour Fund. The general board of studies has appointed Mr. J. E. Purvis, M.A., St. John's, to be University Lecture in Chemistry and Physics in their application to Hygiene and Preventive Medicine for five years. This appointment has been confirmed by the special board for medicine.

BOOKS, ETC., RECEIVED.

ENGELMANN, WILHELM, Leipzig.

Ther die Palliativtrepanation bei Stauungspapille. Von Eugen von Hippel. Price M.3.40.
Nach Diagnosen geordnetes Register für Augenärzte. Von Dr. med. Georg Hirsch. Mit einem Vorwort von Prof. Dr. A. Bielschowsky (in German, French, and English languages). Price W 7

FISCHER, GUSTAV, Jena.

Die Cholelithiasis. Von L. Aschoff und A. Bacmeister. Price M.20.

Pathologie und Therapie der Gonorrhoe. In Vorlesungen. Ein Lehrbuch für Aerzte und Studierende. Von Dr. W. Scholtz. Zweite erweiterte und umgearbeitete Auflage. Price, paper, M.4.50; bound, M.5.50.

Urgent Surgery. By Félix Lejars, Professeur Agrégé à la Faculté de Médecine de Paris. Translated from the Sixth French Edition by William S. Dickie, F.R.C.S. Vol. I. Introductory—Head—Neck—Chest—Spine—Abdomen. Price 25s. net.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication

AHERN, RICHARD, M.B., B.S. R.U.I., D.P.H. Camb., has been appointed Resident Medical Superintendent of the Cork County and City Sanatorium.

ARCHER, T. C. R., M.R.C.S., L.R.C.P. Lond., has been appointed Clinical Assistant in the Eye Department at St. Thomas's Hospital. BENTLEY, A. J. M., M.D., C.M. Edin., has been appointed Lecturer in Tropical Diseases in the University of Manchester.

CHILD, W. N., M.R.C.S., L.R.C.P. Lond., has been appointed Clinical Lecture in the County of Manchester.

CHILD, W. N., M.R.C.S., L.R.C.P. Lond., has been appointed Clinical Assistant in the Surgical Children's Department at St. Thomas's Hospital.
 CHOLMELEY, M. A., M.R.C.S., L.R.C.P. Lond., has been appointed Honorary Assistant Medical Officer to the Royal Cornwall Infirmary.
 COLDICUTT, CLAUDE E. A., M.D. Edin., has been appointed Assistant Medical Officer of Health of the County Borough of Leicester.
 DELISCHAIT, M. E., M.R.C.S., L.R.C.P. Lond., has been appointed Clinical Assistant in the Bar Department at St. Thomas's Hospital.

DESPREZ, HENRY SOULBIEU, L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed District Medical Officer by the Okehampton (Devon) Board of Guardians.

RARLE, H. G., B.A. Cantab., has been appointed Joint Lecturer in Biology at Middlesex Hospital Medical School.

ENGLISH, THOMAS CRISP, M.B., F.R.C.S., has been appointed Surgeon (Non-obstetric) to Queen Charlotte's Lying-in Hospital.

FYFFE, B. L., M.B., B.S. Lond., M.R.C.S. L.R.C.P. Lond., has been appointed Senior Obstetric House Physician at St. Thomas's Hospital.

GEORGE, WILLIAM. M.B., Ch.B. Vict., has been appointed Managery.

Hospital.

GEORGE, WILLIAM, M.B., Ch.B. Vict., has been appointed Honorary Amesthetist to the Royal Lancaster Infirmary.

GRAHAM-JONES, J. L., M.R.C.S., L.R.C.P. Lond., has been appointed Junior Obstetric House Physician at St. Thomas's Hospital.

HOPWOOD, J. S., M.R.C.S., L.R.C.P. Lond., has been appointed Clinical Assistant in the Ear Department at St. Thomas's Hospital.

HUMPHRYS, H. E., M.R.C.S., L.R.C.P. Lond., has been appointed Clinical Assistant in the Skin Department at St. Thomas's Hospital.

HUMPHRYS, G. F., M.B. Aberd. has been appointed to the Skin Department at St. Thomas's Hospital.

Hospital.

HUNTER, G. F., M.B. Aberd., has been appointed Junior Assistant Physician to the Ayr District Asylum.

MCDOUGALL, M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer for the No. 2 District of Southampton.

MACINTYRE, DAVID D. F., M.B., Ch.B. Glasg., has been appointed Medical Officer to the Board of Trade at Liverpool.

MARLOYE, J. C., M.R.C.S., L.R.C.P. Lond., has been appointed Clinical Assistant in the Skin Department at St. Thomas's Hospital

Clinical Assistant in the Skin Department at St. Inomas's Hospital.

MAYBURY, B. C., M. R.C.S., L.R.C.P. Lond., has been appointed Clinical Assistant in the Throat Department at St. Thomas's Hospital.

MAXWELL, R. D., M.D. Lond., F.R.C.S. Eng., has been appointed a Physician to Out-patients at Queen Charlotte's Lying-in Hospital.

MEAKIN, L., M.R.C.S., L.R.C.P. Lond., has been appointed Clinical Assistant in the X-Ray Department at St. Thomas's Hospital.

MORCOM, A. F., M.R.C.S., L.R.C.P. Lond., has been appointed Clinical Assistant in the Throat Department at St. Thomas's Hospital.

MURRAY, CHARLES, M.A., M.D., D.P.H. Aberd., has been appointed Senior Assistant Medical Officer of Health and Schools Medical Officer for the County of Dumfriesshire.

PARKINSON, W. R., M.R.C.S., L.R.C.P. Lond., has been appointed Clinical Assistant in the Surgical Children's Department at St. Thomas's Hospital.

PRESCOTT, N., M.R.C.S., L.R.C.P. Lond., has been appointed Resident Medical Officer at the Guest Hospital, Dudley.

PRIDHAM, F. C., M.R.C.S., L.R.C.P. Lond., has been appointed Clinical Assistant in the Medical Children's Department at St. Thomas's Hospital.

Assistant in the Medical Children's Department at St. Thomas's Assistant Resident Medical Officer at the Whitechapel Union Infirmary.

ROUTH, L. M., M.R.C.S., L.R.C.P. Lond., has been appointed Clinical Assistant in the Medical Children's Department at St. Thomas's

Hospital.

ROWNTREE, CECIL, M.B., B.S. Lond., F.R.C.S. Eng., has been appointed Assistant Surgeon to the Cancer Hospital.

Salisbury, C. R., M.R.C.S., L.R.C.P. Lond., D.P.H., has been appointed Resident Medical Officer to the Central London District Schools at Hanwell.

WINK, C. S., M.R.C.S., L.R.C.P. Lond., has been appointed Clinical Assistant in the Mental Department at St. Thomas's Hospital.

Pacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BIRKENHEAD BOROUGH HOSPITAL. - Junior Resident House Surgeon. Salary £80 per annum and fees.

Brighton, Hove, And Preston Dispensary.--House Surgeon. Salary

£130 per annum, with board and residence.

BRIGHTON, SUSSEX COUNTY HOSPITAL.—Third House Surgeon, unmarried. Salary £50 per annum, with apartments, board, and

married. Salary £50 per annum, with apartments, board, and laundry.

Bristol Royal Infirmary.—Honorary Dental Amesthetist.

Buxton, Wye House Asylum.—Assistant Medical Officer. Salary £120 per annum, all found.

Cancer Hospital, Fulham-road, S.W.—Assistant Amesthetist. Salary 25 guineas per annum.

Chartham, Kext County Asylum.—Third Assistant Medical Officer. Salary £145 per annum, with board, quarters, attendance, and washing. washing.

ELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Clinical

washing.
CHEISEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Clinical Assistant.

DERBYSHIRE ROYAL INFIRMARY.—Two House Surgeons, a House Physician, and an Assistant House Surgeon. Salaries of three former £100 per annum, and of latter at rate of £60 per annum, with apartments, board, &c.

DEVONDORT, ROYAL ALBERT HOSPITAL.—Resident Medical Officer, unmarried. Salary £100 per annum, with apartments, board, &c.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—House Physician. Salary at rate of £75 per annum, with board and residence.

EDMONTON UNION INFIRMARY, Bridport-road, Upper Edmonton.—
Resident Medical Superintendent. Salary £400 per annum, with unfurnished apartments, fire, light, and water.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark Bridge-road, London, S.E.—House Surgeon for six months. Salary at rate of £60 per annum, with total, residence, and washing. Also Ten Clinical Assistants in the Out-patient Departments.

FARRINGODON GENERAL DISPENSARY AND LYING-IN CHURITY, Bartlett's Buildings, Holborn-circus, E.C.—Honorary Physician.

GRIENOCK INTERMARY.—Assistant House Surgeon. Salary £40 per annum, with board and residence.

GRIMSBY AND DISTRICT HOSPITAL.—House Surgeon. Salary £120 per annum, with board, lodging, attendance, and washing.

GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—Assistant House Surgeon. Salary £50 per annum, with board, residence, and laundry Hastings, St. Leonards, and East Sussex Hospital.—Assistant House Surgeon for six months. Salary £20, with board and

HEMBL HEMPSTEAD, WEST HERTS HOSPITAL.—House Surgeon. Salary

£100 per annum, with rooms, board, and washing.

Hôpital Français, 172, Shaftesbury-avenue, W.C.—Second Resident
Medical Officer, unmarried. Salary £50 per annum, with full

and laundry.

WANDSWORTH UNION HOME FOR AGED AND INFIRM, Church-lane,
Tooting.—Assistant Medical Officer. Salary £130 per annum, with

apartments, lodging, and washing.
WEST BROMWICH DISTRICT HOSPITAL.—Resident Assistant

Surgeon, unmarried. Salary £75 per annum, with board, residence, and washing.

EST LONDON HOSPITAL AND POST-GRADUATE COLLEGE, Hammersmith-road, W.—Clinical Assistants, Throat, Nose and Ear, Skin, and X Rays, Pathological Laboratory, &c.; and Three Casualty Officers.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—House Surgeon. Salary at rate of £80 per annum, with board, rooms, and

laundry.
YARMOUTH COUNTY BOROUGH.-Medical Officer of Health. Salary £400 per annum

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Polmont, in the county of Stirling; at Littleport, in the county of Cambridge; at Westport, in the county of Mayo; and at Pewsey, in the county of Wilts.

Births, Marriages, and Deaths.

Campuell.—On Dec. 11th, at Westwood, Brechin, N.B., the wife of Malcolm Campbell, M.A., M.B., F.R.C.S. Edin., of a son.

Eyre.—On Dec. 8th, at Holmsdale, Wandsworth Common, to Dr. and Mrs. Eyre, a son.

Hollist.—On Dec. 8th, at Riseley Lodge, Maldenhead, the wife of Gerald W. C. Hollist, M.R.C.S., a son.

Lee.—On Dec. 9th, at Muswell-rise, N., the wife of William Edward Lee, M.D., F.R.C.S., of a son.

STITT.—On Dec. 11th, at 16, Trinity-road, Bootle, Lancashire, the wife of Robert R. Stitt, School Medical Officer and Police Surgeon, of a son.

UPCOTT.-On Dec. 12th, at Hull, the wife of Harold Upcott, F.R.C.S., a

son. On Dec. 11th, at Woolpit, Suffolk, to Dr. and Mrs. Orby R. M. Wood, a daughter.

DEATHS.

Cross —On Dec. 13th, at Tangley Park, Worplesden, aged 59, Horace Edward Firmin Cross, R.N., Inspector-General of Hospitals and Fleets.

N.B.— A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE CLASSIFICATION OF ODOURS. To the Editor of THE LANCET.

SIR,-I have read with considerable interest Mr. Morris J. Williams's letter and your leading article on this subject. No doubt there is a considerable analogy between colour, sound, and odour, and some classification of the last based upon that which obtains in one of the two former is at any rate conceivable. Dr. S. Piesse takes sound and Mr. Williams colour as his basis, but both are met by the initial difficulty of the absence of an adequate terminology. It is pointed out in your leading article that in this respect odour differs from colour and sound, but I think that too much importance should not be attached to this difference. In all probability we owe our well recognised, though far from exact, terminology of colour to the fact that we have an example of colour graduations so frequently before our eyes In the rainbow and other phenomena of a similar character, where all the colours are vividly represented and accurately arranged according to wave length. But even here there are no words exactly denoting various shades of colour—only the larger distinctions are represented in language. To illustrate this perhaps I may be allowed to quote a passage from one of your contemporaries in which a despairing attempt is made to describe colour in accurate terms: "Greys will be prominent, from a soft elephant toneto which, however, a new name will be attached-to a quite delicate pigeon breast. Blues will be smiled upon, and much care is being pigeon breast. Blues will be sinited upon, and the expended in producing these as cold as possible. They are blues without tone so to sav. and infinitely novel. Greens, saving only out tone, so to say, and infinitely novel. Greens, saving only in fausse tints, are not greatly in evidence; in fact, the colour card throughout points to a falling back to indecisive delicacy of tint. Meanwhile, Paris is declaiming loudly over the loveliness of flamme-voyant red with yellow lights in it, aptly likened to the rays of the setting sun " (The Queen, vol. exxvi., Dec. 4th, 1909, p. 1022). With regard to sound, vibration frequency can, it is true, be expressed with approximate accuracy in the musical notation of our day, but, beyond this, comparison to a known sound or allusion to the emotions which a known sound can produce is all which can be attempted in words. If I may be permitted another illustration I would quote the well-known lines of Shelley in which he attempts to describe the notes of the skylark:-

" All the earth and air, With thy voice is loud, As, when night is bare, From one lonely cloud The moon rains out her beams and heaven is overflowed.

Colour and sound, then, are not so very much better off than odour as regards an accurate terminology.

Mr. Williams's suggestion is ingenious, but I cannot think that the time has yet come for any classification at all. The dependence of odour on volatility (specific solubility in air), molecular weight, and chemical constitution is well recognised, and certain "osmophore groups have been described. But beyond this little is known. Odour is not a force or mode of motion, and if due to vibrations these must be intra-molecular. There is some suggestion that this may be the case, as Professor Francis and I have elsewhere pointed out ("Chemical Basis of Pharmacology," p. 332), and until more is known as to these vibrations any attempt at classification can only be pigeon-holing and must fail to shew any scientific relationship between the bodies classified.

As a small instance of the difficulty which lies in the way of Mr. Williams's own classification I may mention that sulphuretted hydrogen is stated when pure to be devoid of odour (Georg Cohn: Die Riechstoffe, 1904).

With apologies for my somewhat diffuse remarks on this very interesting subject,

I am, Sir, yours faithfully,

J. M. FORTESCUE-BRICKDALE, M.A., M.D. Oxon. Clifton, Bristol, Dec. 12th, 1909.

"DANES' SKINS" AND FLAYING.

THE west doors of churches have for ages been used as notice-boards. This was already the case when few could read and printing had not yet been invented. In the Middle Ages the church doors often exhibited notices or warnings in kind. Thus, our early Saxon forefathers are supposed to have occasionally affixed to the doors of their churches, especially in the eastern counties, the skins of Danes or Northmen whom they had caught red-handed in the act of plunder or sacrilege, and whom they had flayed alive. Numerous fragments of so-called "Danes' skins" are still in existence, and were at one time frequently visible on church doors. Thus Pepys, writing of April 10th, 1661, mentions that he observed the great doors of Rochester Cathedral, "as they say, covered with the skins of the Danes." In the newly opened historical cabinet of the Museum of the Royal College of Surgeons are three fine specimens of Danes' skins, presented by the late Mr. Albert

Way, an authority on this subject. These are labelled, "Portion of human skin, said to be that of a Dane, from the door of the Church of Hadstock, Essex:" "Portion of human skin from the door of the Church of Copford, Essex;" and "Portion of human skin from the north door of Worcester Cathedral." These fragments are of an appreciable thickness-quite the tenth of an inch-and resemble small pieces of felt in appearance. The largest, which is from Copford, and measures about two inches by an inch and a half, is pierced by a nail-hole about half an inch wide, a fact which reminds us that large-headed nails, such as are still used on church doors, were driven through the skin in such a manner as not to interfere with the general design of the ironwork on the door. A piece of Hadstock skin was recently exhibited to the Cambridge Antiquarian Society by Alderman Deck. Commenting on this, the Proceedings of this society remark: "About seventy years ago the door of Hadstock Church needed repair, and under an iron bar nailed across the outside were found pieces of skin." The woodwork of this door is very ancient and shows marks of having been cut by a hatchet, but it is a question, in view of the systematic manner in which the skin was fastened to the door, whether it belonged to a Dane at all. Might it not rather be a relic of the human victim immolated when a temple was anciently built? The belfry or steeple of the early Saxon church might conceivably represent the Pagan temple, on the ruins of which many Christian places of worship were founded. The steeple was certainly a lay meeting-place up to a late date, and it was on the steeple door that the Danes' skins were mostly nailed.

Professor Quekett, who was the first to examine the Danes' skins under one of his powerful microscopes, was in favour of the belief in their Scandinavian origin. In or about 1854 he examined a piece of dark-coloured elastic skin, about the size of a half-crown, from the door of the church at East Thurrock in Essex. The explicit tradition of the locality was that the skin had been bolted on the church door, under an iron plate a foot square, as a warning to marauders, and that it had belonged to "a man who had come up the river and robbed the church." He is supposed to have been flayed alive by the Saxon villagers of the time, but, if so, and if they intended to exhibit his skin as a warning, one wonders why it was bolted down and hidden under a plate of metal. Without knowing anything about the East Thurrock tradition, Quekett pronounced the skin to be that "of a light-haired man, having the hair of a sandy colour.

The Worcester skin in the Museum of the Royal College of Surgeons was also pronounced by this great histologist to be "some part of the body of a light-haired person where little hair grows," and he gave much the same verdict in the case of the Hadstock skin. But light hair is no proof of Danish origin. In fact, this little square of Worcester skin is probably English, and is said to have belonged to a man who was flayed for stealing the sanctus bell from the high altar in Worcester Cathedral. The skin was nailed to the fourteenthcentury woodwork of the north door of the Cathedral in the time of Richard II., but may have been transferred from an earlier door. There can be no doubt that in the early Middle Ages torture must have been almost scientifically practised and that the tortured must sometimes have come under medical treatment or observation. for the victims of the gruesome practice of flaying there could have been little medical aid. They were bound to die. The practice seems to have taken a strong hold of the popular imagination and to have lingered long. Indeed, a case is recorded of a boy being flayed by villains as late as 1700 at Sharnford in Leicestershire. And talk of "skinning alive" still lingers in our slums and in the jargon of our gentle schoolboys.

At Lyons during the first French Revolution flaying is said to have been practised on the bodies of the guillotined. The fact is noticed by Mr. St. George Gray in his valuable notes on "Danes' Skins." The skins so procured were made into boots. At Meudon, according to Montgalliard, human skins were tanned and converted into good wash-leather. Thomas Carlyle speaks of breeches being made from the skins. The epidermis of the male was superior in quality and toughness to chamois; that of the women was so soft in texture as to be almost good for anything. In the case enclosing the Danes' skins at the Royal College of Surgeons is a piece of human skin tanned as leather and labelled in Clift's handwriting. It may very well have come from Lyons or Meudon.

TRAGIC INCIDENT IN OBSTETRIC PRACTICE.

UNDER date, Rome, Dec. 8th, an Italian correspondent writes: "Dr. Masetti, a well-known practitioner, and his colleague, Dr. Vecchi, who were recently called in just before midnight to attend a case of complicated labour, found the conditions of the patient such that, to save her life, craniotomy of the child had to be performed. Leaving his colleague in charge Dr. Masetti hurried home for special instruments, but on his return, having mounted many stairs on his journey to and fro, he was seen to suffer acutely from cardiac distress. With no time to lose, he at once applied himself to the operation, but had scarcely introduced the instrument when, with the exclamation, 'Dio: mi sento male' ('God: I feel ill'), he fell forward, overtaken with syncope. The poor patient, an intimate friend of Dr. Masetti, whom he had often attended in previous confinements, forgetting her own distress in his, looked anxiously on, a keenly interested spectator of the efforts made to bring him round. These proved quite unavailing; the good doctor after not many minutes breathed his last, and his colleague, Dr. Vecchi, on turning to relieve the lady found that she, too, had already collapsed, involving in her own death the already doomed

life of her child. Dr. Masetti had long laboured under weak heart, and the anxiety, combined with the haste and the exertion in running to and fro between the patient's house and his own, had determined the attack to which he succumbed. The incident has evoked much sympathy far beyond the circles, professional and social, in which Dr. Masetti and his patient were known and esteemed."

HEALTH AND SANITATION IN TRINIDAD AND TOBAGO.

THE report on the Blue-Book of this colony for the year 1908-09 has been prepared by the Acting Colonial Secretary, Mr. W. M. Gordon, and is now published as a Parliamentary paper. The present population is estimated at 343,945. The number of births recorded in 1908-09 was 11,638, while the deaths were 7941, the birth-rate being 33.84 per 1000 and the death-rate 23.09. There was during the year no unusual prevalence of diseases incident to the climate, but an outbreak of bubonic plague, which was confined to Port-of-Spain and suburbs, occurred on May 30th. Between this date and Sept. 25th 19 cases occurred of which 15 resulted in death. The preventive measures adopted were isolation of contacts, special scavenging by sanitary gange, and destruction and bacteriological examination of rats. 3 cases of yellow fever also occurred, 2 in Port-of-Spain and 1 in San Fernando. Towards the close of the year the regulations dealing with the breeding places of mosquitoes were strictly enforced by the prosecution of householders on whose premises any stagnant water containing mosquito larvæ were found. These prosecutions resulted, in most cases, in the offenders being fined by the court, and the result has been satisfactory. Four-fifths of the premises in Port-of-Spain are now connected with the sewerage system, and the remainder will be sewered in the near future. The ravines and drains in the suburb of Belmont have been concreted, and the work of filling in the low-lying lands of the Woodbrook suburb has been continued, with the result that a number of possible breeding places of mosquitoes has been greatly diminished and cases of malarial fever are fewer and less virulent. In view of the distrust with which the health conditions of Trinidad appeared to be viewed by some of her sister colonies in the West Indies, the following statistics are quoted in which the mortality of the colony is compared with that of other colonies. According to the latest available records (those for 1907-08) the death-rate per 1000 in Jamaica was 37.25, in British Guiana, 36.9; and in Barbados, 26.86. For the same period (1907-08) the death-rate per 1000 in Trinidad was 25.6, which fell during last year to 23 09. It will thus be seen that the health conditions of Trinidad compare very favourably with those of the principal West Indian Colonies. The climate of Trinidad is hot but not unhealthy, and while the heat is sometimes oppressive during the day at certain seasons, the nights are almost invariably cool and conducive to sleep. Europeans who lead regular lives enjoy good health in most parts of the colony without the necessity of taking any special care or precautions, though there are certain districts in which malarial fever is common and care required. The number of admissions into the hospitals of Port-of-Spain and San Fernando during the year was 6093 and 2715 respectively. Of the total number discharged from both institutions 2714 were cured, 4871 were relieved, and 252 were recorded as not improved. The total number of deaths in the two hospitals was 967. There are also district hospitals at Arima, St. Joseph, Tacarigua, Couva, Prince's Town, Cedros, and Tobago, with an aggregate number of patients on March 31st, 1909, of 177. Special hospitals likewise exist in Trinidad and Tobago for the treatment of yaws patients. In the former there were on March 31st, 1909, 182 patients, as against 165 on the same date last year; in the latter there were 218, as against 109 a regrettable increase of 100 per cent. In the Leper Asylum there were 251 inmates on March 31st, 1909. The number of patients admitted during the year was 60; the discharges were 38 and the deaths 38.

THE WEIGHT OF HAND-FED INFANTS. To the Editor of THE LANCET.

SIR,—Can any reader of THE LANCET give a table showing the average weight of infants fed by hand every month from birth, and giving the information separately for the sexes. There are published tables for those raised on mother's milk but not for those otherwise reared. Infants not fed on mother's milk seem heavier. I should be glad of a reference to any published tables or to hear of any original observations if not yet published.

I am, Sir, yours faithfully,

Dec. 13th, 1909.

ENQUIRER.

OBSTETRICS AMONGST THE ANNAMITES.

Dr. Moti, who is now a lecturer in the Military Medical School of Val de Grâce, describes in La Semaine Médicale of Dec. 1st the practice of Annamite midwives as seen by him when he was stationed in Tonkin. The patient lies on a charpoy, under which a brazier of glowing embers is arranged so that the hot air ascends to the genital organs, thus warming the parts and doubtless acting beneficially, being to some extent sterilised. When the woman groans other women who surround the bed cry or chant also so as to drown the patient's cries. If the labour does not progress rapidly enough a woman carefully balances herself on the patient's liiac crests and with her heels over the fundus of the uterus applies the amount of pressure she thinks needed. This always seems to prove effectual, for Dr. Moti during the two years he was in the country never had to apply forceps.

Although dirty rags are used as diapers and though the woman gets up in a few hours and goes on with her ordinary avocations septic complications are extremely rare. This may perhaps be partly explained by the hot-air treatment but is largely due to the avoidance by the midwives of all digital interference.

THE MANUFACTURE OF NITRO-BENZOLS AND ANILINE COMPOUNDS.

To the Editor of THE LANCET.

SIR,—Can any of your readers afford information, or refer me to any work or papers relative to the constitutional and local effects produced in the manufacture and handling of nitro-toluois and nitro-benzols, and in addition any prophylactics in use, and the local and general treatment of disturbances caused thereby? Are local irritations caused in the manufacture of aniline and its compounds?

I am, Sir, yours faithfully, S. F. C.

Dec. 11th, 1909.

A SOCIOLOGIST ON THE TREND OF MODERN MEDICINE.

Mr. H. G. Wells has been unburdening himself of certain suggestive "Scientific Anticipations" in the Christmas number of T.P.'s Weekly, which is largely devoted to a "symposium" of opinions on the question "Whither are we tending?" in which Mr. Arnold Bennett, Mr. T. P. O'Connor, the Rev. R. J. Campbell, and Mr. G. K. Chesterton discuss literature, Parliament, faith, and social evolution respectively. Mr. Wells begins his discussion of medicine as follows: "The general mass of the medical profession, equipped with a little experience and a muddled training, and preposterously impeded by the private adventure conditions under which it lives, goes about pretending to the possession of precise know-ledge which simply does not exist in the world." But after this bitterness he proceeds to speak with considerably more hopefulness as to the future of medicine. Indeed, he is inclined to think that science will advance chiefly along the lines of increased biological knowledge in its widest sense, for "masked, misrepresented, limited, and hampered, the work of establishing a sound science of vital processes in health and disease is probably going on now, similar to the clarification of physics and chemistry that went on in the later part of the eighteenth, and in the early years of the ninetceth, centuries." Mr. Wells also looks forward to the time when medicine will "take over this great hinterland of human interests which legitimately belong to it," as assuredly it is doing already. He proceeds to speculate upon the future possibilities of surgery, and anyone with a knowledge of the unlimited rein which Mr. Wells gives his imagination will not need to be assured that he predicts wonderful achievements on the operating tables of the future. In support of his expectations he quotes the belief of the late Sir Michael Foster. The doctrine of Metchnikoff could hardly have escaped his attention. After repeating that revolutionary scientist's indictment of the large intestine he continues "If a gentleman called upon me 'done up' in the way I am dimly suggesting, with most of the contents of his abdomen excavicated, his lungs and heart probably enlarged and improved, parts of his brain removed to eliminate harmful tendencies and make room for the expansion of the remainder, his mind and sensibilities enhanced, and his liability to fatigue and need of sleep abolished, I should conceal with the utmost difficulty my inexpressible disgust and terror. But then, if M. Blériot, with his flying machine, ear-flaps, and goggles, had soared down in the year 54 B.C., let us say, upon my woad-adorned ancestors at Dover, they would have had entirely similar emotions. And at present I am not discussing what is beautiful in humanity, but what is possible—and, being possible, is likely to be attempted." But having thus made his readers' flesh creep, the prophet of surgical progress closes on a more pleasant note, suggesting that man may yet come to such wisdom as to cultivate physical perfection without the intervention of the knife, and that, if we read aright the promise of modern therapy, is the future of medicine to which we may, indeed, look forward with longing and some slight hope. The dictum of John Hunter should never be forgotten that the necessity for operations is the reproach of surgery.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Bye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed swolusively "To THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that carly intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTI-FIGATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS, not used.

MANAGER'S NOTICES. TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

Until the end of the present year copies sent by post will be charged at the rate of $7\frac{1}{2}d$. inland and 8d. abroad.

Commencing with the issue of Jan. 1st, 1910, the rates of subscriptions, post free from THE LANCET Offices, will be :-

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs. 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA-Messrs. WILLIAM WOOD AND Co., 51, Fifth Avenue, New York, U.S.A.

Communications, Letters, &c., have been received from-

A.-Mr. J. Astier, Asnières; Mr. J. W. Arrowsnith, Bristol; Messrs, D. Appleton and Co., Lond.; Mr. E. Arnold, Lond.; Dr. R. Ahern, Lond.; Dr. James F. Allen, Pietermaritzburg; Mr. F. Algar, Lond.; Dr. T. R. Atkin-son, Chadwell Heath.

The Lancet of the second at all Messrs, W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements or Subscriptions should be addressed.

The Lancet can be obtained at all Messrs, W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Remarks

THE EFFECTS AND USE OF RADIUM.¹

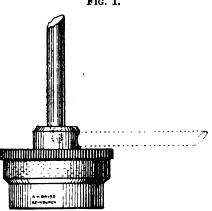

Delivered before the Edinburgh Medico-Chirurgical Society on Dec. 1st, 1909,

By DAWSON TURNER, M.D. Edin., F.R.C.P. Edin., M.R.C.P. Lond., F.R.S. Edin.,

MEDICAL ELECTRICIAN TO THE ROYAL INFIRMARY, EDINBURGH, ETC.

MR. PRESIDENT AND GENTLEMEN,—Mr. Butlin's interesting paper in THE LANCET of Nov. 13th on radium in the treatment of cancer and some associated conditions has suggested to me that perhaps my own five years' experience in the use of this remedy might be of some service. In 1903 I purchased 20 milligrammes of radium bromide, in January, 1904, 10 milligrammes, while in the electrical department of the Royal Infirmary, Edinburgh, I have had charge of 15 milligrammes.

Radium applicators and containers.—All the specimens were in sealed glass tubes except the one of 10 milligrammes, which was in an ebonite case with a thin mica window; this specimen also was quite pure with an activity according to the Curie method of measurement of 2,000,000. To contain this latter specimen I have recently had a small aluminium box made by Baird, Lothian-street, Edinburgh, with a lid which screws on tightly enough to make a water-tight joint; the bottom of this box is only 1-5th of a millimetre thick, so that it is practically quite transparent to the beta and gamma rays. There is a hole in the lid of the box into which an aluminium rod can be screwed so as to facilitate applying the specimen to the interior of the mouth or other cavity (Fig. 1). Last April I went to Paris to study the

Radium applicator.

methods at the Radium Institute and saw their tviles radiferes and other applicators, but I have made no use of these myself. The amount of active salt is spread out into so thin a layer that I doubt their radiating efficiency except for the most superficial condition, and if any screen, such as even a thin piece of indiarubber, be used to prevent their being damaged by an ulcerating surface the rays that would penetrate the screen would be comparatively few in number. I have also an osophageal applicator made by Martindale. With the apparatus I have used I have been practically limited to the different varieties of beta rays and gamma rays. Alpha rays can be obtained from the toiles radiferes and plasters provided no screen at all be used, but these rays would be stopped by the first layer of the tissues and would therefore only influence that layer.

Radium rays appear to have two chief actions: (1) a specific action on certain pathological conditions such as rodent ulcers, cancerous nodules, angiomas, keloids, cicatrices, and fibrous contractions; and (2) an action producing inflammation and destruction somewhat similar to that produced by caustics and burns. Sometimes the one action and sometimes the other may be used, and often both are

1 The address was illustrated by an exhibition of patients and of lantern slides.
No. 4500.

The curative action of radium on a rodent ulcer is an example of its specific action. After a sufficient exposure the floor of the ulcer will be observed to gradually fill up, the raised edges to subside, the surface to contract, until finally the part will be covered with fresh rather transparent skin. As a rule no pain at all will be felt, and there may be but little inflammation, but the part may dry up under a scab. This is an ideal treatment and an example of the "cito, tuto, et jucunde."

If radium be applied in a sufficient dose to the healthy skin there will be observed in the course of a few hours to some days a red spot which will become slightly raised and a little tender; over this a scab may form resembling, as Wickham has pointed out, an impetigo crust; this may persist for a time or be replaced by another, but the final result will be good. I have not observed any tendency to form the obstinate and painful X ray sore.

The dose of radium ought to be measured by the product of the strength of the preparation and the length of the exposure—what would be termed electrically "the ampère hours"; but these quantities would be modified by the presence of screens.

The effect of the screens is to cut off the less penetrating rays, and so to protect the skin or superficial tissues. For only those rays which are absorbed by the skin can affect it. All the rays of radium can be cut off by a sufficient screen except the gamma rays, and the latter are few in number. If a superficial condition is to be attacked use no screen and give a comparatively short exposure. The alpha rays now predominate; they are very powerful, but feebly penetrating. If a subcutaneous condition is to be treated use a screen of aluminium of about one-third to half a millimetre in thickness, or a lead one of about one-tenth of a millimetre, and give a longer exposure. The thicker the screen the less the skin will be affected, but the longer the exposure. Only the beta and gamma rays will now be of use, for a thin sheet of notepaper is sufficient to stop all the alpha rays. If the disease be still deeper use a lead screen, one-fifth to one millimetre in thickness, and give a prolonged exposure. Only the hard beta and gamma rays will get through, and they are few in number. A prolonged exposure is therefore necessary.

After treatment.—As a rule, no after dressings are necessary; leave the part alone. Bad results are atrophies and telangiectases; they may be the result of an overdose.

Conditions in which radium may be of service.—Amongst these are: rodent ulcer, angiomas, keloids, cicatrices and fibrous contractions, warty growths, simple ulcers, malignant growths, pruritus.

Now to refer to some of the cases I have treated.

RODENT ULCER.

CASE 1.—A male, aged 46 years, consulted me in 1906; he was suffering from a rodent ulcer on the nose; it was of the size of a sixpence, punched out, and of about a year's duration. He was treated by the X rays, applied two or three times a week for about three months, but without much benefit. Radium was now tried and 18 applications of 20 minutes each (six hours in all) caused it to heal over with a soft supple scar. In this case five milligrammes of radium bromide of an activity of 300,000 were used. He has since had three recurrences, each of which has yielded rapidly to two or three fresh applications.

CASE 2.—A patient, aged about 50 years, recommended to me by Dr. M. Burnett, consulted me about a rodent ulcer of 6 years' duration placed close to and invading the inner canthus of the eye. It was a little smaller than a sixpence. I shielded his eye with lead foil, and gave him in all 5 hours' treatment with 10 milligrammes of pure radium bromide; no shield except a thin piece of parchment paper was used. In one month's time he was completely cured, and there has so far been no recurrence. This case illustrates the necessity for pushing the treatment beyond what would otherwise seem to be required if a recurrence is to be avoided.

CASE 3.—A somewhat similar case, but in an older gentleman, recommended to me by Dr. G. Carmichael. The ulcer measured $2\frac{1}{2}$ by $1\frac{1}{4}$ inches, was excavated and had very prominent raised edges. It was of many years' duration. It was treated with 10 milligrammes of pure radium bromide enclosed in an aluminium box one-fifth of a millimetre thick for 4 hours weekly. Improvement was slow but steady, and now after a total of 18 hours' exposure the ulcer is almost healed. This was a large ulcer to attack with a radiating surface of radium of only 1 centimetre in diameter and each application was made in a different spot. In Paris they would

Ç

no doubt have treated this case with a radium plaster, so as to attack its whole surface at once, but, as I have already explained, the density of the radiation would have been much weaker, and I doubt whether a quicker result would have been obtained than by my method of applying the whole quantity to a small area at a time. If we express the exposure in the above case according to the method I have suggested it would be one of 180 milligramme-hours.

ANGIOMAS.

Case 4.—A female patient, aged 24 years, recommended to me by Professor Alexis Thomson. On the left side of the face there was a very large port-wine stain roughly divided into three parts. It extended from the roots of the hair above the ear down to the level of the mouth, and it was about 4 inches in breadth; it was almost entirely superficial. Many remedies had been tried unavailingly. A photograph of the face was taken on April 26th, 1909 (Figs. 2 and 3), and treatment was then begun. 10 milligrammes of pure radium bromide, protected by a mica shield and a sheet of tissue paper, were applied for an hour at a time to different areas; no area was exposed a second time until all reaction had passed off. The applications were at first followed by headaches. When subsequent applications were made to a spot which had been previously treated a more intense reaction followed. This patient has now had

involving portions of the hard and soft palates. been ill for about a year, and a full course of iodides and of mercury had been taken without benefit. Professor Thomson had on two occasions excised portions of the growth for microscopic examination without clearing up the diagnosis. Had the diagnosis been that it was definitely cancerous he would have attempted to remove it, but failing such a diagnosis the operation seemed too serious a one to subject the patient to. This patient was at first treated with the X rays by a tube, whose prolongation could be inserted in the mouth. After 20 applications had failed to produce any benefit radium was tried. 10 milligrammes of pure radium bromide were placed in the aluminium applicator I have already described, and by means of the rod were maintained by the patient against the growth for about an hour at a time. Improvement began at once and after ten hours' exposure, total 100 milligramme-hours, I sent him to be re-examined by Professor Thomson; the latter wrote on Nov. 25th, 1909: "Decidedly improved, especially on the left side, where healing appears to have started." This patient is still under treatment.

CASE 7.—A patient, aged 70 years, recommended by Dr. McEwan, was admitted to the electrical department on Oct. 15th, 1909. She was suffering from a papillomatous growth on the left cheek. Ten years previously a similar growth had been removed and there had been no recurrence

FIG. 2.

Nævus before treatment with radium.

51 hours' exposure, or 510 milligramme-hours. The result is a great improvement. Over about half the original area the natural colour of the skin has been restored; it is, in fact, difficult in some places to make out the original extent of the disease. In other places white atrophic spots have appeared, due, no doubt, to over-exposure. In other places as yet untreated the original stain persists.

untreated the original stain persists.

The case is an interesting one; it shows the value of the treatment in this intractable condition and the number of hours exposure that may be required. Subcutaneous nævi are more amenable. I will refer only to one.

CASE 5.—A baby, aged 6 months, recommended by Dr. James Graham. On the right side of the baby's nose was a capillary nævus about the size of a sixpence. This started as a small spot and has grown rapidly. 10 milligrammes of radium bromide were applied without any shield except the mica window for 20 minutes, total 3·3 milligramme-hours. Three days afterwards a white patch appeared in the middle of the nævus and spread over its whole surface. This case must be watched, but it is quite probable that no further application will be necessary.

CARCINOMA AND ASSOCIATED CONDITIONS.

Case 6.—A male, aged 59 years, recommended by Professor Alexis Thomson, was admitted to the electrical department of the Royal Infirmary on August 13th, 1909, suffering from a neoplasm, probably of a transition type,

Nævus after partial treatment with radium.

for some seven months. During the last year the growth had extended rapidly. It now measured 2 inches by $\mathbf{1}_{2}^{\perp}$ inches and it projected about half an inch from the surface of the skin. Treatment with radium was begun on Oct. 15th, and on Nov. 25th the patient was discharged, the growth having disappeared. The total exposure was 43.3 milligramme-hours.

I will not refer in detail to three other cases of malignant disease, two of recurrent scirrhus with secondary deposits and one of sarcoma, because in each case the disease was too far advanced to expect success, though in each some benefit seemed to result. There is not much opportunity of treating early cases of malignant disease with radium, for in the present state of our knowledge early operation offers the best chance, but I should recommend the use of radium after operation to attempt to prevent a recurrence, and from the experience I have gained in such cases I feel confident that its use is attended with benefit.

Other conditions, for which I have used radium, are warts, for which it acts the part of a charm, cicatrices with fibrous contractions, lupus and lupus erythematosus, leukoplakia, and pruritus. It is of decided benefit in the latter condition. With regard to leukoplakia, I have a patient of Dr. J. Struthers just now under treatment who has suffered for the last year from this condition and from ulcers at the front of the tongue. For the last three months

she has had pain in eating and has only been able to take soft food well soaked. She has had so far two applications of one hour each of 10 milligrammes of the pure salt; this is equivalent to 20 milligramme-hours. She returned after this to say that all discomfort in eating had disappeared and that she had again been able to enjoy hard food. One of the ulcers had healed, but enough time has not elapsed (one week) to expect any alteration in the leukoplakia.

THE VACCINE TREATMENT PYORRHŒA ALVEOLARIS (ALVEOLAR OSTEITIS).

BY KENNETH GOADBY, M.R.C.S. ENG., L.R.C.P. LOND., D.P.H. CANTAB.,

PATHOLOGIST AND LECTURER ON BACTERIOLOGY, NATIONAL DENTAL HOSPITAL; LECTURER ON ORAL HYGIERE, LONDON SCHOOL OF TROPICAL MEDICINE.

In an earlier communication 1 I have called attention to the various types of bacteria which are to be found in chronic suppurative diseases of the human gums, and I have shown that a large number of cases generically termed pyorrhoa alveolaris might be advantageously treated by means of vaccines prepared from the infecting organisms isolated from the pus. Since those communications were published I have had further opportunity of investigating and treating alveolar osteitis, or pyorrhœa alveolaris, as it is commonly called.

For the general purposes of description the cases of suppuration of the alveolus of the jaw may be divided into two classes: (1) those which exhibit some constitutional disturbances, referable to (a) intoxication, and (b) direct bacterial invasion; and (2) those showing no constitutional disturbances of a definite type, but which have from time to time various minor pathological manifestations about the oral mucous membrane.

The general symptoms associated with suppuration of the alveolus are not always in direct proportion to the amount of local disease observed along the gum margin. Many of the cases included in the tables below are ones in which the pus was small in amount, or even only recognisable on microscopical examination, whereas in others in which considerable suppuration existed along the whole of the alveolus in the upper and lower jaw the constitutional symptoms were only slight. In 4 of the cases recorded all the teeth had been removed on account of their looseness, but the constitutional symptoms, although greatly improved, did not entirely disappear, while in one case the removal of the teeth produced considerable aggravation of the existing intestinal disease.

In 32 of the cases the suppuration was not general, but was confined to individual teeth or groups of teeth. In some of the other cases, although the suppuration was general, the amount of loss of the alveolus was not great, and the teeth had not become denuded of their bony attachments. In several cases the suppuration was undoubtedly started by artificial bridges and crowns. Gold cap crowns, particularly when fitting badly (as they usually do), are notoriously the predisposing cause of many alveolar pyorrhœas.

In dealing with pyorrhœa alveolaris the dental surgeon is frequently placed upon the horns of a dilemma; the patient's doctor has traced the origin of some chronic ill-health, anæmia, or gastro-intestinal symptom to disease of the mouth, and he sends the patient to the dental surgeon to remove the septic cause—i.e., teeth. There may be considerable pus formation, and yet the pockets around the affected teeth may not be deep, the alveolar processes may not be so far destroyed as to have caused direct loosening of the teeth and there is no pain, the patient is therefore exceedingly adverse to removal of all the teeth. If the peridental membrane and alveolar processes are so far damaged that no efficient socket remains, the dental surgeon is in no perplexity as to what should be done, but where the teeth are not so far affected the decision as to treatment is more difficult. It is in these cases that bacterial knowledge and treatment by means of suitable vaccines is the proper course so adopt, for not only can the general symptoms of disease

be eliminated, but the local condition can be so far treated that the teeth may be retained and the suppuration cured.

Four distinct phases of alveolar osteitis are to be recognised; it is quite possible that these constitute two different disease entities.

Type 1.—The gums and the teeth appear perfectly normal. Here and there slight depressions may be noticed between individual teeth, and careful examination in these regions will exhibit the presence of a certain amount of pus, sometimes only to be recognised microscopically, showing the interdental bone has already become affected, and a photograph shows distinct loss of the bony tissue.

Type 2.—The condition is characterised by easily bleeding gums which are slightly detached from the teeth; there is a great increase of interdental space with loss of the interdental bone which becomes softened.

Type 3.—The hypertrophied gum noted in the second type for the most part becomes shrunken, but there is marked injection of the vessels passing up from the buccal surfaces; the bone in various directions has become removed, not only between the teeth, but in the anterior and posterior surfaces of the alveolar plate. Patches of osteoporosis or rarefying osteitis are scattered about the alveolus, and in many instances the bone has become so thinned that a fine-pointed probe or hypodermic needle may be passed right through the aw almost at the level of the roots of the teeth with little more opposition than when passing it through a thick towel. The infected mucous glands which I have described elsewhere 2 are also seen near the infected areas.

Tupe 4.—The teeth are all loose in their sockets, the alveolar process has become absorbed, the gums are boggy, sinuses may be found here and there in the mouth, and as a rule marked fœtor of the breath is present.

The fector of the breath may be an early or late symptom, and depends for its presence on the special types of organisms. It is particularly foul when the bacillus necrosis is present, and has a sweetish-sour smell in the presence of the saccharomyces neoformans.

Of the 51 cases tabulated below (39 females and 12 males) 36 were cured in that all the general symptoms, ansemia, toxemia, weakness, and chronic intestinal dyspepsia, cleared up together with the local suppuration. Nine were relieved; that is to say, the general symptoms disappeared, though the local discharge remained. Two cases died—one of rheumatoid arthritis, the other of lymphatic leukæmia. Four of the cases were not treated by vaccines but by extraction only; three of these cases have developed other symptoms, which are referable to the original chronic intoxication, and the fourth case recovered entirely.

Bacteriology.

As in several previous communications I have dealt at length with the bacteriology of the group of diseases associated under the term pyorrhoea alveolaris, it is only necessary to mention the organisms isolated and used as vaccines.

The methods adopted in dealing with the cases have been: microscopical examination of the films made from the pus, leucocyte and blood count, estimation of hæmoglobin, and differential blood count. The films were stained with Gram's and Leishman's method. The organisms present on the films vary enormously, and the following bacteria are recognisable by their morphological forms: leptothrix racemosa of Vicentini, the bacillus fusiformis, the three varieties of mouth spirochætes, a large number of organisms belonging to the diphtheroid group, diplococci, streptococci, streptobacilli, and yeasts. A very large number of other morphological forms, some of them often classed as leptothrix, have also been found; one organism is sometimes present, a bacillus generally occurring as diplobacilli anaerobic in habit, growing out into long threads in liquid media, and producing a very large amount of evil-smelling gas, which may be classed as the bacillus necrosis. In the films stained by Gram's method the leptothrix racemosa retains the stain, as do some of the diphtheroid bacilli, some of the cocci, and the yeasts; the other organisms decolourise.

Agar streaks were made from the pus, under the usual precautions to eliminate adventitious forms, and wherever possible from an extracted tooth; the organisms were plated out and the individual bacteria isolated and tested on the usual cultural media. A large number of organisms were

isolated, but in order to determine the particular infecting organism in the individual case recourse was had to the method of the opsonic index originally described by Sir Almroth Wright, and in a manner described in one of my earlier papers. The various bacteria in each case, which gave an opsonic index either considerably above normal or considerably under, were presumed to be causal agents of the disease.

The bacteria isolated and determined in this manner; were streptococci of the longus type belonging either to the streptococcus fæcalis or streptococcus angiosus groups of Andrewes and Horder. The pneumococcus was found at times, but the staphylococcus aureus was more common. The staphylococcus aureus met was more common. with in the mouth is characterised by the production of a duller pigment than the staphylococcus aureus occurring in other suppurative lesions; it is somewhat rare for it to have the bright orange pigment generally associated with the name. The orange pigment may develop after a number of subcultures, especially when potato is used as the medium. Another type of staphylococcus not infrequently found, as the tables show, is the staphylococcus citreus granulatus described by Freund. This organism differs from the other staphylococci in being Gram-negative, and is often confounded with the micrococcus catarrhalis, which latter organism is present amongst the Gram-negative cocci A number of organisms of the micrococcus catarrhalis type have also been recognised as causal agents in the suppuration, but these organisms by no means all conform to the catarrhalis type in that they frequently produced fermentation of one or other of the carbohydrates upon which they were tested; but the general type of a nonliquefying non-Gram-staining coccus of somewhat large dimensions with a curious oat-like form has been the type of organism under which I have grouped the micrococcus catarrhalis.

The saccharomyces neoformans has been found four times in the present series, in two of the cases with severe local symptoms. It is not so frequently present as the other

bacteria cited, but in most of the cases in which I have met with it, in addition to those described here, these yeasts have been present in the hypertrophied gum tissues. I have also met with it in new growth of the sarcomatous type in the mouth, and, as I have elsewhere secribed, this organism when inoculated into animals produces metastatic growths closely simulating sarcoma.

The last type of organism which I have found present amongst these 51 cases is a bacillus belonging to the somewhat ill-defined group of so-called diphtheroid bacilli. The organism, which closely resembles the diphtheria bacillus in its staining reaction in that it gives a positive reaction with Neisser; it does not produce toxemia when inoculated into guinea-pigs subcutaneously but produces localised suppuration if any reaction occurs. There are two varieties, one which ferments cane sugar and lactose, and the other which is uncertain in its fermentation; the colonies of the one on agar are minute grey, exceedingly sticky and produce a brownish growth upon the surface of the agar, whilst the streaks of the other organism are yellowish in colour, often almost orange, on the surface of potato; this organism shows the lesser amount of fermentation of the carbohydrates. I have met with these diphtheroid bacilli in chronic periosteal swelling associated with local mouth infection, more particularly in the region of the wisdom teeth.

A considerable number of other bacteria have been isolated and tested from these cases; but as they gave no agglutination with the patients' serum, no marked deviation from the normal as regards their opsonic index, and on inoculation into animals no local or general pathological lesions were produced, their causal relation to the suppuration is probably little or nil, and they have therefore not been included in this account.

In a recent paper which Eyre and Payne⁷ have published they record the causal organism in 33 cases of pyorrhœa alveolaris. The micrococcus catarrhalis is described by them as the predominant organism, it having occurred alone in 15 of the cases, and in conjunction with the streptococcus,

pneumococcus, or staphylococcus aureus in others. They have also described the streptococcus, pneumococcus, and staphylococcus as occurring alone or in conjunction with other bacteria. Their findings corroborate what I have elsewhere stated with regard to the bacteria found, although in my original paper I was not prepared to group all the non-Gram-staining organisms of the coccal type into one group of catarrhalis owing to their differing in their cultural reactions. I am still inclined to regard the various cocci which are to be found in the mouth, and which do not stain by Gram's method, as belonging to a very wide group related on the one hand to the meningococci, and on the other hand to the gonococci, while the catarrhalis may be regarded as an intermediate group.

Method of Treatment.

The method of treatment adopted in these cases has been the preparation of a specific vaccine from the given case, the organism or organisms chosen for the vaccine being, as I have already explained, those which showed a deviation from the normal in their opsonic index to the patient's own serum. The vaccines have been prepared in the ordinary way adopted in my laboratory; a small amount, 0.2 per cent., of trikresol is used as a preservative. As a rule, constitutional disturbance has been rare after the introduction of the vaccine, but in a few instances well-marked constitutional disturbances followed, such, for instance, as vomiting, acute headache, and general malaise, and in a few cases where the opsonic index was abnormally low to the organisms used as a vaccine (although the dose given has been properly reduced) the constitutional disturbances have been very definite and were considerably prolonged. It is not uncommon when the micrococcus catarrhalis is used as a vaccine to get constitutional disturbance closely simulating an acute coryza, particularly in those persons who are susceptible to the common cold. When rheumatic symptoms are present an exacerbation may be looked for, but it does not, as a rule, occur unless the doses be too large.

As far as possible the treatment has been controlled by an examination of the opsonic index of the blood, but small variations have not been regarded as of great moment. Considerable variation in the index has been observed to take place immediately after the inoculation and following two or three of the earlier vaccinations, but after this, although the dose may be increased, the amount of response, as evinced by the determination of the opsonic index, is not great, and the clinical conditions, local and general, must be taken into account. After plotting out a considerable number of opsonic curves I am of opinion that the response to inoculation is definitely shown. I consider, therefore, that, although the error of observation of the opsonic index may be a large one owing both to personal equation and mechanical errors, to say nothing of physiological variations of the leucocytes used, the opsonic index still gives a very considerable amount of information with regard to the progress of the cases, and should not be dispensed with.

Local Treatment.

It is perhaps scarcely necessary to lay down any special lines of local treatment in addition to the method of immunising, as each case requires to be treated individually and from a general surgical standpoint. It is obviously impossible to expect that the denuded peridental membrane of the teeth, the destroyed alveolus, or the shrunken gum will return to the condition which existed prior to the disease by homologous immunisation or any other means that can be devised. All that can be hoped for is to arrest the progress of the disease, to prevent the further destruction of the bony tissue, and where there still exists some framework of the bony tissue around the teeth, such tissue may undergo regeneration.

It follows, therefore, that, where the so-called pockets exist around individual teeth, recourse must be had to active surgical methods. In my own hands the use of the actual cautery has been attended with the best results, the cautery wounds healing quickly and rapidly after previous immunisation has been undertaken. Much knowledge of the local condition may be obtained by the use of the X ray photograph, and it is well in the early stages to determine how far absorption has taken place before recourse is had to surgical measures. Antiseptics are of little avail in the treatment of pyorrhœa, and antiseptic mouth-washes never

gain access to the sockets of the teeth unless they are forcibly applied by means of a fine-nozzled syringe, but scrupulous cleanliness is essential both after the removal of the loosened gum and during the process of treatment, the mechanical action of adhering food naturally tending to interfere with the healing of the tissues.

In the accompanying tables of the cases under discussion a short epitome is given of the cases treated along the lines outlined herein. The general symptoms associated with the cases and referable to the mouth disease embrace many ill-defined symptoms pointing to slow toxic absorption or to definite bacteriæmia. The persistent bronchial catarrh, often with localised symptoms suggestive of early tubercular disease, is to be found; gastro-intestinal symptoms, nausea, sometimes vomiting, with occasional diarrhæa alternating with constipation, are common. Still more common are rheumatic pains, called variously muscular rheumatism, end at times even gout; and anæmia of a septic type is, as might be supposed, common.

Enlargement of the lymphatics in the neck is not, as a rule, well marked, but on careful examination thickened chains of lymphatics may often be found with distinctly enlarged and often tender lymphatic glands. There is generally but little pain referred to the mouth or teeth, but often neuralgia of a fleeting type is attributed either to the head or neck, and occasionally the face. In the early stages, or in the first two types of the disease as cited above, pain on mastication may be complained of, or a sensation of itching of the gums. In such cases individual teeth are generally found to be quite loose, while the majority of the

teeth are sound.

The chief disadvantage of this method of treatment is its necessarily prolonged nature, but as the majority of cases which come for treatment are of four or five years' standing at least, it is not surprising that the cases must be kept under observation for many months.

New Cavendish-street, W.

Medical Societies.

OPHTHALMOLOGICAL SOCIETY.

Staphylococcio Conjunctivitis.—Guttate Choroiditis.—Guttate Iritis.—Myopic Degeneration of Lens.—Congenital Narcoma of the Orbit.—Lymphosarcoma of the Lacrymal Gland.—Exhibition of Cases and Npecimens.

A MEETING of this society was held on Dec. 9th, Mr, W. H. H. JESSOP, Vice-President, being in the chair.

Before the papers of the evening were read Mr. JESSOP alluded in very sympathetic terms to the recent demise of last year's President, Mr. R. Marcus Gunn. He alluded to the large number of contributions which the late distinguished member had made, all marked by great accuracy and care in observation. Mr. Jessop also dwelt affectionately on Mr. Gunn's social qualities, and his faculty of endearing himself to all with whom he was brought in contact. It was resolved to send a letter of condolence to Mrs. Gunn and family.

Mr. R. W. DOYNE read a paper describing a form of Conjunctivitis in which the Meibomian Glands were affected with Staphylococcus Aureus. This he described as giving rise to definite acute attacks, especially after exposure of the eyes. He also pointed out that many cases described as chronic conjunctivitis were due to this cause, as well as many other cases of marginal blepharitis. Mr. Doyne showed a member of a fresh family suffering from Guttate Choroiditis, which he described some years ago, and gave a brief description of the condition. He also read a brief note on a condition that he described as Myopic Degeneration of the Lens, and had pointed out the condition to the society in 1886, when he showed a patient suffering from this form of nuclear degeneration. He also read notes of a form of Iritis, which he described as guttate iritis, occurring in elderly and gouty persons. It presented the appearance of one or more warts at the pupillary margin of the iris, which came on without any noticeable inflammatory appearances, and sometimes disappeared without giving rise to any inflammation. At other times inflammatory symptoms appeared, and adhesions

to the lens took place.—Mr. N. B. HARMAN, in discussing the first paper, said that seven years ago he made bacterial cultures from the normal healthy eyes of school children by passing a platinum loop along the mouths of the Meibomian glands, and in every case he got enormous numbers of the staphylococcus aureus and albus. -- Mr. Doyne, in reply, asked members to look out for such cases and endeavour to ascertain the exciting cause, but for five days nothing but water should be used in the eyes. - Mr. Doyne's other papers were discussed by Mr. E. NETTLESHIP, Mr. T. HARRISON BUTLER, and Mr. J. E. ADAMS.

Mr. M. S. MAYOU read a communication entitled "A Congenital Sarcoma of the Orbit." He pointed out that the interest of this case lay partly in its extreme rarity and partly in its clinical resemblance to proliferating cysts. male, aged 12 days, was admitted to the Central London Ophthalmic Hospital on March 13th, 1908. No eye had been seen since birth on the left side. The patient was a strong, healthy infant and presented no other congenital abnormalities. The right eye was to all appearance normal. Filling the left orbit and protruding from between the lids, which could not be closed, was a red, slightly edematous mass. It was irregular on the surface and covered by the epithelium of the conjunctiva except where it was exposed in the palpebral aperture, where it had started to ulcerate. There was no enlargement of the pre-auricular gland and no eye could be seen. On March 13th the orbital contents were eviscerated, leaving the eyelids in position. The child made a good recovery, the wound granulating and healing over with epithelium. On June 16th, 1908, the child returned to the hospital with a large recurrent mass filling the entire orbit bulging forward the upper lid and protruding beneath it. Complete evisceration of the orbit was performed, the child making a good recovery. After the operation the patient attended the hospital for four weeks, but since then had been lost sight of. The contents of the orbit submitted for examination were hardened in formol. The eye, which was embedded in the upper part of the tumour, had been cut open and the sclerotic divided posteriorly in several places. It appeared about the normal size, the cornea, anterior chamber, iris, ciliary body, and lens being normal. The condition of the posterior part of the globe could not be made out, but there was no evidence of any cystic protrusion therefrom. No definite orbital structure could be recognised, the whole being involved in the tumour. It was composed of mediumsized spindle cells. The walls of the vessels within the tumour were composed for the most part of its cells. Hæmorrhages had taken place into the growth in many situations. The recurrent tumour, examined microscopically, exhibited the same characteristics as the primary tumour, except that the hæmorrhages were not so numerous. The typical microscopical appearances, together with the recurrence of the disease, led him to believe it to be a spindlecelled sarcoma of the orbit during intra-uterine life. He had been able to discover the records of two similar cases which exhibited much the same characteristics.

Mr. A. P. L. Wells and Mr. Mayou communicated a paper on Lymphosarcoma of the Lacrymal Gland. They pointed out the want of proper classification of tumours of the lacrymal gland. They divided them into those derived from the epithelial, the connective, and the lymphoid tissues. The case of a woman, aged 66 years, which they brought before the society was one of the latter type. The patient was admitted to the Central London Ophthalmic Hospital on Jan. 14th, 1909. She was a strong, healthy woman; there were no anæmia and no glandular enlargement. There was nothing in her previous history of note. She complained of a swelling which she had noticed for a considerable time at the upper and outer part of the left orbit in the situation of the orbital portion of the lacrymal gland. The surface of the swelling was somewhat irregular and of about the size of a large walnut. It was soft, almost fluctuating, rounded in outline, and moderately freely moveable. From January to April, whilst under observation, it gradually increased in size, and on admission into the hospital on April 8th there was, in addition to the above symptoms, displacement of the eye downwards, and the tumour seemed to have become slightly attached to the margin of the orbit, which seemed thickened. There was no enlargement of the salivary or lymphatic glands and no signs of dissemination. On April 9th an incision was made over

the tumour, which was found to be encapsuled except in one situation, where it was ruptured. After removal it was seen to be of about the size of a walnut and surrounded by a capsule which was evidently formed from the original capsule of the gland; this was composed of fibrous tissue and was much thicker in some places than in others. In some situations it was much infiltrated by the cells of the growth, whilst in one the tumour had penetrated it. The tumour consisted of round cells of about the size and shape of an ordinary lymphocyte and showed no signs of degeneration, although in some places the cells were more darkly stained and packed closer together than in others. Mitosis was not marked in the cells. The vessels in the tumour were of two kinds. Some, which were evidently new, were composed of a single layer of endothelium, or in some situations of the cells of the tumour itself; the others, which were generally situated in the remains of the trabeculæ of the gland, and were probably the original vessels supplying it, had normal coats which were somewhat thickened. In the literature they had been able to find eight similar cases which exhibited much the same characteristics. The points about the tumours were the late age at which they occurred, all the patients being over 38 years of age; their slowness of growth, from 3 to 4 years; and the absence of glandular enlargement. They also pointed out that these tumours should be differentiated from other orbital sarcoma invading the gland, and from lymphoid growths such as are found in chloroma and lymphadenoma.-Mr. A. W. ORMOND discussed the case.

The following cases and specimens were shown:-Mr. S. Stephenson showed a case of Tubercle of the Choroid, shown originally on Oct. 17th, 1907.

Mr. BISHOP HARMAN showed three cases: 1. Abnormal Congenital Pigmentation of one Eye. 2. Retinitis Nævus. 3. The Diaphragm Test (finished models of the instrument and its accessories).

Dr. RAYNER D. BATTEN showed an Orbital Frame for Eye-glasses, and its adaptation for a ptosis prop.

Mr. A. H. PAYAN DAWNAY: Opacities of the Cornea of an unusual character.

Mr. M. L. HEPBURN exhibited a case of Hæmorrhages of the Macula.

Brighton and Sussex Medico-Chirurgical SOCIETY.—A meeting of this society was held on Dec. 3rd, Mr. C. J. Jacomb-Hood being in the chair.—Dr. E. Wethered showed a case of Ataxic Paraplegia, with a malignant growth of the palate engrafted on an old tertiary syphilitic scar.—Dr. C. F. Bailey exhibited three cases of Rodent Ulcer treated by means of X rays with satisfactory results.—Mr. A. J. Hutchison showed a microscopic specimen of Aspergillus Niger from an ear. The patient had come to him with the ear tightly packed with epithelial débris. When this was removed the walls of the meatus were seen to be much inflamed. Cheesy matter again formed, in which aspergillus was found. Spirit of wine dropped into the ear, diluted at first and gradually increased in strength up to pure spirit, seemed to be the only satisfactory treatment.—Mr. R. F. Jowers showed two Appendices which he had removed. The first was from a man aged 30 years. It was of unusual size and showed a fæcal calculus in situ at the proximal end. The patient recovered. The second specimen was one of intussuscepted appendix which was removed from a man aged 48 years, a heavy drinker. He was admitted to hospital after a third attack of appendicitis. The appendix appeared to be only about one and a-half inches long, and was directed inwards from the cæcum. Within the cæcum and corresponding in position to the proximal end of the appendix could be felt a rounded tumour of the size of a chestnut, with a dimple on it corresponding to the cæcum. Dense adhesions existed where the appendix disappeared into the bowel. The cæcal wall was divided close around the appendix and the latter removed, the opening into the cæcum being closed with a double row of continuous sutures. The patient made a good recovery.—Mr. H. H. Taylor showed a case of Albuminuric Retinitis. - Dr. Williams showed a case of Ulcerating Scleroderma. —Dr. C. H. Benham read notes of some cases treated by Vaccine Therapy. -Dr. Walter Broadbent read a paper on Aortic Regurgitation. He remarked that Corrigan in 1832 wrote his classic account of aortic regurgitation and stenosis, but mitral regurgitation and stenosis were not really differentiated till 40 years later.

Rheumatism was the principal cause of aortic regurgitation, but nearly 25 per cent. of the cases were due to syphilis. Women suffered from it less than men, because their Aortic disease was only half as vascular tension was lower. In rheumatic cases the valves common as mitral disease. were puckered, but the intima of the aorta was smooth; in syphilitic cases portions of the valves were destroyed, and the wall of the aorta was affected for an inch or more above the valves; in atheromatous cases the valves were stiff but not destroyed, and the whole arch of the aorta was athero-The heart might be exceedingly large in rheumatic cases. Of physical signs the most striking was the visible pulsation of the carotids and other vessels, and one of the most important was the absence of the second sound in the neck when there was much destruction of the valves. He discussed the causation of the pulsus bisferiens, and mentioned the great difference between the systolic and diastolic blood pressures. He also went fully into prognosis and treatment.

LIVERPOOL MEDICAL INSTITUTION.—A meeting of this society was held on Dec. 2nd, Dr. T. H. Bickerton, the President, being in the chair. - Dr. N. Percy Marsh read a paper upon Modern Methods of Infant Feeding, and introduced the subject by pointing out the importance of maternal nursing as a factor in the reduction of the present high infantile mortality. He then described the differences, both qualitative and quantitative, which exist between human and cow's milk, and the importance of the enzymes in nutrition and the consequent desirability of avoiding their destruction He recommended by the employment of sterilisation. pasteurisation at 155°F. for the destruction of bacteria and described Freeman's apparatus which he used for that He strongly advocated the percentage method of feeding, especially in those cases of malnutrition in which the assimilative capacity of the infant had been impaired by previous improper methods. The details of percentage feeding were described, firstly when employed through the agency of milk laboratories, and, secondly, the home methods as advocated by Holt, in which by the use of "top milk" containing 10 per cent. or 7 per cent. of fat variations to suit the requirements of any particular case could readily be made. Cases illustrating the various methods employed were described, and in conclusion he stated his belief that percentage feeding was far and away in advance of any method which he had, in an experience extending over many years, previously adopted.—The paper was discussed by the President, Dr. F. Heatherley, Dr. O. T. Williams, cussed by the President, Dr. F. Heatherley, Dr. C. I. Whitans, and Dr. H. Armstrong, and Dr. Marsh replied.—A very interesting exhibition of cases was then held, medical cases being shown by Dr. R. J. M. Buchanan, Dr. A. Gordon Gullan, and Dr. Nathan Raw; surgical cases by Mr. F. T. Paul; diseases of children by Dr. Marsh, Dr. V. C. De Boinville, Dr. Peter Davidson, and Mr. R. C. Dun; ophthalmic cases by Dr. Charles G. Lee, Dr. K. A. Grossmann, Mr. Edgar Stevenson, and Mr. Hugh E. Jones; ear cases by Mr. E. M. Stockdale; and skin cases by Dr. F. H. Barendt, Dr. G. G. Stopford Taylor, and Dr. R. W. Mackenna.

Rebiews and Notices of Books.

Fifty Years of New Japan. Compiled by COUNT SHIGENOBU OKUMA, late Prime Minister of Japan, and edited by MARCUS B. HUISH, Vice-Chairman of the Japan Society. London: Smith, Elder, and Co. 1909. Two vols. Pp. 646. Price 25s. net.

JAPAN, for every sort of reason, political, ethnological, and sentimental, is of the greatest interest to all our citizens, and Mr. Marcus Huish has done a real service by editing this excellent and authoritative work of Count Okuma and his fellow contributors. These handsome volumes tell the story of the growth of Japan since its formal entry upon a sensationally rapid career from powerless and prejudiced insularity to its present position as a first-class power. It is 56 years since the old feudalism of Japan fell and the islands sprang into the new life of a united nation, since which time by a wisely selective adoption of the political institutions of

Western civilisation the empire has progressed to a point which arouses not only the admiration but the apprehensions of some other products of that civilisation. These volumes have been compiled by Count Okuma, who has been both Prime Minister and Minister for Foreign Affairs in Japan, with the assistance and coöperation of the highest authorities on the various subjects, and they narrate the history of a kingdom and a constitution in their making with a happy blend of breadth and particularity. The vast scope of the work is due to the statesmanlike qualities of the compiler; the accuracy of detail follows upon the fact that the foremost contemporaries of the rejuvenated nation have written chapters upon the departments in which they have exceptional knowledge and experience. The work was originally published in Japan last year as a record of the 50 years subsequent to the opening up of the country to foreign intercourse—namely, from 1854 to 1904, and most of the contributors in the first instance only brought their facts up to the time of the Russo-Japanese war; but in the English edition the information is carried as near to the present date as possible by the use of recent statistics and all other available information.

We do not make any attempt to review this work either as a most interesting history or as a valuable contribution to the science of sociology. That it is both will be obvious to the most casual reader, but we can only call attention here to the interesting section dealing with the development of the science of medicine in Japan. Professor Kazutami Ukita in the eighth chapter of the second volume makes the first definite mention of medical science in Japan, saying that the art of healing was from olden times in great repute in the country, "being called the art of benevolence—and a skilled physician was considered equal in merit to a good statesman," which is rather an apt confirmation of Mr. H. G. Wells's scheme in "A Modern Utopia," where he definitely places members of the medical profession among the samurai. Professor Ukita tells the story of Ryotaku Moeno, popularly known as Rankwa (which means Hollandisation), the father of Japanese medicine, whose determination to become a physician led him to learn Dutch. How this man met Gempaku Sugita, who had been born in a house of hereditary surgeons, and came to translate the Tafel Anatomia into Japanese is an extremely interesting story. These two, with a third named Junan Nakagawa, became a centre for the study of Dutch in Japan and must be regarded as the real founders of medicine in Japan. But their date was 50 years before the opening up of Japan; all that their work and the work of their pupils and derivatives could effect was to prepare the soil for Western influence by eliminating some of the gross superstitions of Chinese practice, China being the original source of aboriginal Japanese medicine. But from the time that Japan consented to open her ports, Japanese medicine on a Western basis, with information derived almost entirely from the Dutch, flourished extensively, and the Chinese pathology, which was found wanting when tried by actual dissection, fell into disuse.

Professor Ukita's tale of medical and hygienic development in Japan is here taken up by Professor Tanémichi Aoyama, Dr. Ukabu Fujikawa, and Professor Hiizu Miyaké, who write with great detail and clearness. The first two writers show that the beginning of the healing art in Japan, as in other countries, was intimately associated with magic and divination, but it is interesting to note that even at the time of the mythical ages in Japan that country possessed a system of treating diseases in which bleeding and the use of hot springs figured. This balneotherapy was probably founded on right lines, but during the first century B.C. the influence of Korean civilisation produced a change in the methods of treatment, and subsequently on the introduction

of Confucianism and Buddhism the Japanese medical art became intimately associated with philosophy and religion. With the introduction of Chinese medicine a medical school was founded containing departments which in some respects corresponded with the divisions with which we are familiar in our own medical schools to-day, though special departments for the study of shampooing and acupuncture sound somewhat strangely to the modern ear. The students, who were brought up at State expense, studied seven years for internal medicine and five for pediatrics or surgery. The Chinese school flourished in opposition to the Dutch until just before Commodore Perry's famous visit, after which intercourse with America and England, and later with Germany, confirmed the Japanese in the study of Western medicine. Medical education has now attained to a considerable degree of perfection in Japan. There are at present, besides the medical college of the Imperial University of Tokyo, two other colleges of medicine at Kyoto and Fukuoka. There are also eight medical schools, five of which are maintained by the Government. According to the latest returns, the medical practitioners number over 36,000, of whom 15,000 have studied Chinese or Old Dutch medicine, while some 7000 have received the latest medical education in schools and colleges. Those who have studied in private schools and under individual doctors have to pass an examination held twice a year before they are allowed to commence practice. There are over 10,000 practitioners of this class. The steady progress of the country in the art and science of medicine has been assisted by the fact that graduates from the universities in Europe and America are given licences to practise without examination.

In hygiene, both public and domestic, and in nursing, military, civil, and private, the debt of the Japanese to England and America is freely acknowledged, while the completeness with which the Japanese have seized upon such modern ideas as medical and hygienic associations, public laboratories and bacteriological institutes, children's hospitals and hospitals for the segregation of infectious cases, can only be qualified as marvellous.

This is a most interesting and valuable book.

LIBRARY TABLE.

Whitaker's Almanack, 1910. London: 12, Warwick-lane, E.C. Pp. 989. Price 2s. 6d.—Hazell's Annual, 1910. Edited by HAMMOND HALL. London: Hazell, Watson, and Viney. Pp. 608. Price 3s. 6d. - Who's Who. 1910. Pp. 2162. Price 10s. Who's Who Year Book. Pp. 154. Price 1s. The Writers' and Artists' Year Book. 1910. Pp. 124. Price 1s. net. The Englishwoman's Year Book. Pp. 382. Price 2s. 6d. net. London: Adam and Charles Black.-The Year Book of the Scientific and Learned Societies of Great Britain and Ireland. London: Charles Griffin. Pp. 356. Price 7s. 6d.—Regularly with the approach of Christmas these year-books reach our office, and there are no books that we can commend more cordially to the notice of our readers who desire to keep themselves acquainted with current affairs. "Whitaker's Almanack" is now 42 years old, but it shows no sign of declining vigour. On the contrary, besides its usual features, which, as we are told on the title-page, comprise "the astronomical and other phenomena," this year time is taken by the forelock and the "vast amount of information respecting the Government finances, population, commerce, and general statistics of the British Empire" which the work rightly claims to give, comprises a detailed account of the changes which will occur in Customs and Excise, licences and stamps, taxes and death duties, should the present Budget become law. The retrospect of the past year is particularly full and includes a survey of most of the chief regions of human

activity. Under the Scientific Summary reference is made to cancer research, consumption, eugenics, hypnotism, the Pasteur Institute, the Radium Institute, rat extermination, the ultra microscope, and the Whisky Commission. Other leading articles deal with naval and army reform. old age pensions, aeronautics, social progress, Poor-law relief, secondary education, and public and private wealth. An adequate summary of the existing condition of foreign countries is given. In a word, "Whittaker" is as indispensable as ever .- "Hazell's Annual" has attained its first quarter of a century, and has marked the occasion by the introduction of several new features. The index has been improved both as to type and completeness, and a number of signed articles upon important current topics are presented, amongst which is one upon Radium by Sir Oliver Lodge. There is a fair review of scientific progress during the past year, including medicine and surgery, which, though it refers to the International Congress of Leprosy, makes no mention of the International Congress of Medicine at Budapest. The rest of the Annual contains its usual amount of carefully compiled information. -Of "Who's Who" there is no new thing to be said, but we will repeat that it is a necessary book of reference to all who require to keep in touch with men and affairs. It is a valuable compendium of biographies, in many cases contributed by the subjects who comprise nearly all the public people in this country, with a few foreigners added. The task of editing such a volume so as to please everyone's sense of proportion is obviously impossible, and the old fault remains that the less obvious an individual's claim may be to inclusion the longer may be his autobiography. The book has grown to 2162 pages, and has as a companion volume "Who's Who Year Book," which is made up of tabular lists of people in official or other prominent positions, and other useful information printed in a readily accessible manner. - "The Writers' and Artists' Year Book "will be found of service by the ever-increasing body of people who desire to supplement their incomes by occasional journalism, as well as to professional writers, containing as it does the information necessary for the disposal of all kinds of literary and graphic wares.—"The Englishwoman's Year Book "is of especial interest to mothers exercised in their minds upon the problem of "Unmarried Daughters," which has been so recently brought forward for public debate in the Times. It contains a clear summary of the means of entry, and to some extent of the prospects, of the many professions and callings now open for women. The index has been enlarged, and amongst the new articles are those on the position of women in European countries, copyright, research work, and science. There is a section describing the medical charities and convalescent homes available for women and children.— The scope of the "Year Book of the Scientific and Learned Societies of Great Britain and Ireland" is indicated by its title. It is compiled from official sources and contains full information concerning the bureaus of all the learned societies in this country, with a brief account of their work during the past year.

New Year's Diaries and Calendars.—A New Year's gift which is always acceptable to a medical man is a good pocket or desk diary, since if he cannot find anybody to give him one he will have to obtain it for himself. We are able again to commend in this respect both the productions of Messrs. John Walker and Co. and the well-known Letts's Diaries published by Messrs. Cassell and Co. Messrs. Walker make a special feature of neat and convenient pocket cases containing note-books of various dimensions, and especially useful is the arrangement of the pages devoted to the owner's personal accounts. Even the financial ignoramus, who is not uncommon in the medical profession, can hardly muddle his annual budget if

he adopts one of these little books. The same firm's calendars for the waistcoat-pocket are also neat. Letts's Diaries are probably known to most of our readers and are issued in the usual styles at a moderate cost. We can recommend especially the cloth-bound No. 10 Diary, which is of a handy size and contains a deal of useful information in the preface. In the same series Messrs. Cassell issue a small and compact medical diary reduced to its simplest form. Many of these publications of both firms carry with them a coupon insuring their holder against accident. Amongst the best medical diaries we have seen is that of Messrs. John Wright and Sons (Bristol), which has reached its seventeenth edition, and the chief feature of which is the ingenious insertion of half-leaves by which the record of a whole month's visits to 40 patients can be seen at one "opening" of the book. At the same time such comparison requires the utmost neatness of entry, and we should advise practitioners to look upon all pocket account-books of this class as useful note-books only, or at most, as day-books, and not be tempted to let them replace the ledger as a record of their professional transactions which may assume much importance in the event of the sale of a practice or of a legal dispute.

Months of the Year. By the Rev. PEMBERTON LLOYD. London: W. H. and L. Collingridge. 1909. Pp. 307. Price 5s. net.—The object of the reverend author in writing this book is so good that he somewhat disarms criticism from a literary point of view. A great admirer of rural England, and a profound believer in the value of the influences of the country upon the population, he has written a desultory book round the months of the year, telling the main characteristics of the plants and flowers that grace each season. Interspersed with this information are talks about the church festivals as they occur, and about the sports peculiar to the periods, the whole compost being permeated through and through with quotations from a wide range of reading. The author is a convinced and vehement believer that the salvation of England lies in the revivifying and reorganising of village life. Moreover, as a good clergyman he is confident that this village life-happy, contented, and dignified in its peace and culture as he would have it-must centre round the Established Church. Unfortunately the forces of sociology and political economy make many of us find the cry of "back to the land" one which cannot be shouted vehemently; while still more certain is it that if a clerical element is insisted upon in any such movement unanimity is lost. We do not think that this book, which is evidently the result of much labourlabour which the author has enjoyed, will bring him many adherents to his views, but apart from that he is to be congratulated on having incorporated in his pages so much pleasant and diversified reading.

JOURNALS AND MAGAZINES.

The Proceedings of the Royal Society of Medicine. Vol. III., No. 1. November, 1909. London: Longmans, Green, and Co. Price 7s. 6d. net.—Even though the Royal Society of Medicine is not satisfied with its house, the publication by which the scientific world judges it continues to be of a quality that does credit to it. In carefulness of editing, in type, paper, and illustrations, the first number of the new year shows no departure from the high standard set by its predecessors. A large part of it is occupied by the presidential addresses of the different sections, most of which have appeared, in abstract at least, in these columns. Dr. Leonard Williams's thoughtful address to the Balneological and Climatological Section, entitled "To Redress the Balance," comes first by alphabetical right, and in the same section Mr. J. J. Eyre writes on the Hygiology of Naples. The remaining presidential addresses reported

are by Dr. Samuel Sloan on Electro-Therapeutics in Gynæcology, in the Electro-Therapeutical Section; by Dr. James Niven on Poverty and Disease, a suggestive discourse, in the Epidemiological Section; by Dr. H. Macnaughton-Jones on Pain Associated with Disorders of the Female Genital Organs, in the Obstetrical and Gynæcological Section; by Mr. William Hern on the Relation of Dentistry to Other Branches of Medicine and its Bearing upon the Public Health in the Odontological Section, to which Mr. A. Hopewell-Smith contributes a paper on Infective Disease of the Jaws Associated with Absorption of the Teeth; by Mr. Rickman J. Godlee on Prognosis in Inflammatory Diseases of the Lungs and Pleura, commonly treated Surgically, in the Surgical Section; by Dr. F. W. Mott on the Present Position of the Neuron Doctrine in Relation to Neuro-Pathology in the Pathological Section, which is followed by a report from Mr. S. G. Shattock on a case of Rhabdomyoma of the Urinary Bladder. The Section for the Study of Disease in Children is occupied by clinical reports, following upon a paper on Subacute Liver Atrophy and Liver Pathology in Childhood, by Dr. A. Dingwall Fordyce. The Clinical and Dermatological Sections are also filled with case reports. In the Medical Section is Dr. Robert Maguire's paper on the Treatment of Oxalate Calculus which we published recently. In the Surgical Section is Dr. William B. Coley's paper on the Treatment of Inoperable Sarcoma by Bacterial Toxins, which aroused much interest at the time of its delivery; and in the Therapeutical and Pharmacological Section a discussion is opened by Sir T. Clifford Allbutt, followed by Professor William Osler on the Teaching of Therapeutics in Hospital Wards.

Looking Back.

FROM

THE LANCET, SATURDAY, Dec. 24th, 1831.

EXTRAORDINARY CIRCUMSTANCE.

To the Editor of THE LANCET.

SIR,—As your pages are frequently devoted to the communication of interesting subjects, not exclusively connected with physiology, I should feel obliged by your insertion of the following well-authenticated narrative, which, if it cannot be satisfactorily explained, may serve as a caution against rash vows, and that impious dissatisfaction which some express at the providential dispensations of that God, who governs all events with unerring wisdom.

The wife of a Mr. Higgins, a farmer of Baltonsborough, near Glastonbury, Somerset, having brought him three daughters in succession, and no son, he was so disconcerted at the repeated disappointment, that he vowed, should his next child be a daughter, he would never speak to her. On the approach of his wife's fourth confinement, he repeated this vow. To his great joy, his wife gave birth to a son, and nothing occurred to lessen his satisfaction, until the child began to speak. To his astonishment and distress he then found, that, while the boy would readily address his mother and sisters, and, indeed, any female, nothing could induce him to utter a word to his father, or any male person. This singularity continued during the whole of his father's life (30 years); entreaties, threats, or promises, were of no avail, and the unhappy man frequently bewailed, with tears, the distressing consequence of his rash vow.

On the death of Mr. Higgins, which happened about two months since, the young man, to the astonishment of all who knew him, began to speak fluently to males as well as females, although for thirty years previously he had never been heard to utter a word to any one of the former sex. Mr. Higgins had no other son; he is in good health, and is ready, as are his mother and sisters, and many other respectable persons, to attest the truth of this narrative.

I am, Sir, your obedient servant, Warminster, Dec. 9th, 1831. JOHN HOARE, M.R.C.S., &c.

The Editor of THE LANCET added the following cautious comment:—"We insert this communication as we received it, but offer no comment on its contents."

THE LANCET.

LONDON: SATURDAY, DECEMBER 25, 1909.

THE ANNUS MEDICUS 1909.

It is, perhaps, an arbitrary custom which leads us year by year to carry out a medical stock-taking at Christmas time, for if Science has no frontiers she assuredly knows no limitation of months or years. That Medicine has advanced during the last 12 months we have no doubt, though the time is too early to pick upon any given piece of recorded work and point to it as the beginning of a new principle or the embryo of a method of treatment with which great things will be wrought. task is to record rather than to criticise. Perhaps, indeed, the present stock-taking has left out of notice some innovation big with future hope, for a survey of such a nature, whatever pains be spent upon it, must necessarily fall short of completeness, but we are encouraged to continue the custom of our predecessors and to add another chapter to the history of modern medicine that has been compiled in these pages and in its present form for 40 years, nearly half the lifetime of THE LANCET. Year by year the chapters have grown longer, and space forbids us to make each of them more than an expanded index, but it is, we trust, a discriminating index. Each year, too, the record of medical events, not strictly scientific, becomes longer, as medicine and hygiene enter more prominently into the counsels of the nation and into the daily consideration of our countrymen, as is abundantly evident in this story of the Annus Medicus for 1909.

MEDICINE.

Tuberoulosis.

The principal medical event of the year, which we notice in a separate section, was the Sixteenth International Medical Congress held at Budapest. At that congress, which is fully noticed in another section, no definite pronouncement was made in regard to the treatment of pulmonary tuberculosis, and such would have, perhaps, been premature. The employment of tuberculin in small doses has been further adopted, the remedy being given either by the mouth or hypodermically, and the time of administering it being regulated by the temperature chart. Considerable success is claimed by this method, but the time that has elapsed since it was introduced is too short to allow of any definite conclusions being formed. The results, however, are decidedly encouraging, and more extended trials are certainly desirable.

Important suggestions have been made in respect to the prophylaxis of pulmonary tuberculosis. Two interesting official papers have been published—one, the report of the British delegates to the International Congress on Tuberculosis at Washington, and the other a memorandum by the medical officer of the English Local Government Board, which is intended to supplement the Public Health (Tuberculosis) Regulations, 1908. The delegates to the Washington Congress lay stress in their report upon the coördination

between public and charitable organisations, and it is doubtless desirable to make more use in this country of the several organisations which already exist. It may not be always practicable or desirable to institute dispensaries for the tuberculous, as has been done in more than one continental country, but it is an easier matter to adapt existing dispensaries to the necessity of the situation. The memorandum of the Local Government Board is intended primarily for the use of Poor-law medical officers who are now required to notify cases of tuberculosis coming under their care. The general scheme of the memorandum is one which we welcome, because many points, not all, for which we have contended in THE LANCET for many years are fully accepted. The absolute necessity is urged of differentiating between the acute infectious diseases and tuberculosis in the matter of infectivity, and the fact is emphasised that the infectivity of the latter is low and not improbably only operative under certain conditions of deprivation, overcrowding, or other eminently unwholesome circumstances. The emphasis laid in the memorandum upon the importance of doing nothing which will deter the patient from following his occupation is excellent. "Above all," it says, "the investigation must not pursue inquiries in a manner, or give information, that may prevent a consumptive patient from continuing to earn his livelihood." As a result of all the steps proposed the medical officer of the Local Government Board looks forward to a quicker decline in the death-rate from tuberculosis than has hitherto been experienced, although, he adds, "results cannot be measured with accuracy except after the lapse of a considerable number of years." The Tuberculosis Prevention (Ireland) Act encountered a good deal of opposition in its passage through Parliament, and was considerably modified in the process, but its operations are bound to be beneficent to the country.

The subject of tuberculosis in children is rightly attracting considerable attention. In a paper read before the Washington Congress, and subsequently published in our columns 1 Dr. THEODORE SHENNAN recorded some interesting statistics obtained as the result of an investigation of the post-mortem records of the Royal Edinburgh Hospital for Sick Children. 1085 cases came under review, of which 413 died from tuberculosis. These cases were examined in two series, the first containing 105 and the second 308 cases. 68 per cent. of the children were under five years of age. The lymphatic glands were tuberculous in 97 cases (92.4 per cent.) in the first series and in 243 cases (78.8 per cent.) in the second series. The mediastinal glands were more often affected than the abdominal glands, and dissemination took place more frequently, apparently, from the former group. Tuberculosis of the mediastinal glands was commonly unaccompanied by primary tuberculosis of the lungs, but was frequently accompanied by recent tuberculosis of these organs, in many cases evidently secondary to the gland tuberculosis. Primary ulceration of the intestines, in the absence of any previous excavation of the lungs, was frequently found. It was usually accompanied by caseation of lymphatic glands, mediastinal or abdominal, or both simultaneously. tables drawn up by Dr. SHENNAN refer to children of the poorer classes, and it would be interesting to know in what respects, if at all, statistics dealing in a similar manner with children of the better classes would disagree with those given in the communication under consideration. Dr. J. ALLAN also published an article insisting on the importance of the early recognition of tuberculous mediastinal glands in children, so that by appropriate treatment the progress of the disease may be checked or cured. In the Address in Medicine delivered before the British Medical

¹ THE LANCET, Jan. 30th, 1909, p. 315.

Association at Belfast, Dr. R. W. PHILIP touched in a masterly manner on many points in connexion with the outlook of modern medicine on tuberculosis. He pointed out that the physician and the sanitarian had joined hands, and had been aided not a little by educated social workers who recognised the vast part played by tuberculosis as an agent of national devitalisation and impoverishment. He likewise drew attention to the frequency of tuberculous infection in childhood, and laid stress on the relatively airless conditions of home and school life, especially among the children of the poor. He pointed out that the ratio of increase of pulmonary tuberculosis is greater about the time the child goes to school; also that one morbid influence seems constant throughout the progressive stages of the child's life-namely, the comparative withdrawal of the developing organism from the natural and healthful stimulus of the open air.

The question as to the presence of tubercle bacilli in the blood in tuberculosis has again engaged the attention of bacteriologists. Dr. R. C. ROSENBERGER, Assistant Professor of Bacteriology in the Jefferson Medical College, published the results of his investigations in the American Journal of the Medical Sciences for February. He came to the conclusion that in all forms of tuberculosis there is bacterizemia. He found that even in cases undergoing recovery the bacilli could be demonstrated in the blood, though in small numbers. The importance of these observations is obviously great, but though they appear to have been carefully made, the sweeping conclusion that the tubercle bacillus is always present in the blood in tuberculosis will not be accepted without confirmation.

Typhoid Fever.

Lieutenant-Colonel D. SEMPLE, R.A.M.C. (retired), and Captain H. S. MATSON, I.M.S., have carried out a series of investigations in order to ascertain the effect of heat and chemical agents upon antityphoid vaccines. Briefly stated their results are as follows: 1. The sterilisation of antityphoid vaccine can be efficiently accomplished by the addition of 0.5 per cent. carbolic acid. 2. Heating a vaccine in order to sterilise it introduces a harmful and unnecessary element which acts in two ways—(a) it diminishes its immunising properties; and (b) it curtails its keeping properties. In the experiments recorded by these observers the deleterious effects of heat are clearly shown. 3. Antityphoid vaccine sterilised by the addition of 0.5 per cent. carbolic acid retains its immunising properties unimpaired for two years at least. This is proved (a) by the fact that animals and men treated with a two years old vaccine prepared by this method show the same blood changes as those treated with a fresh vaccine similarly prepared; and (b) by the fact that animals treated with a two years old vaccine prepared by this method withstand the same amount of a virulent typhoid culture when given intraperitoneally as those treated with a fresh vaccine similarly prepared. 4. Animals inoculated with antityphoid vaccine sterilised by the addition of 0.5 per cent. carbolic acid attain a higher degree of immunity (as proved by blood changes and the resistance to lethal doses of a virulent typhoid culture) than similar animals inoculated with a vaccine sterilised by heat (60° C. for 20 minutes, or 53° C. for one hour) and the subsequent addition of an antiseptic (carbolic acid 0.5 per cent., or lysol 0.25 per cent.). 5. An antityphoid vaccine sterilised by heating for 20 minutes at a temperature of 60° C., and the subsequent addition of 0.5 per cent. carbolic, has considerably deteriorated after being kept for two years, as proved by the blood changes and effects of lethal doses of a virulent typhoid culture in animals inoculated with this vaccine. 6. Pure carbolic acid to the extent of 0.5 per cent. would appear to be the best agent with which to sterilise bacterial vaccines, and the

authors consider that its general adoption would obviate any necessity for heating.

Dr. A. CASTELLANI has experimented with attenuated live cultures in typhoid fever. He maintains that the use in man of the live typhoid fever vaccine prepared according to his method (heating of non-virulent broth cultures at 50°C.) is not dangerous. He considers that it induces a higher degree of immunisation than the ordinary vaccines consisting of dead cultures. Though both inoculations may consist of live vaccine without danger, the routine method of antityphoid vaccination which he recommends, and which he now uses, is the inoculation of a half cubic centimetre of the usual dead vaccine (Wright), followed in a week's time by the inoculation of one cubic centimetre of live vaccine. He also states that mixed vaccines may be prepared by using dead or live attenuated cultures of typhoid and dysentery, or typhoid, paratyphoid, and dysentery.

Dr. S. T. IRWIN and Dr. T. HOUSTON published in our columns an interesting account of a "typhoid carrier" successfully treated by the inoculation of typhoid vaccine. The apparent success of this case suggests that vaccine-therapy may furnish, in some cases at least, an effective means of dealing with these carriers of infection, whose existence certainly furnishes a new and difficult problem in epidemiology. The important question of typhoid "carriers" is discussed under the section devoted to Public Health.

Cerebro-spinal Meningitis.

Dr. W. Dow has conducted an investigation into the leucocytosis of epidemic cerebro-spinal meningitis. He found that in the epidemic form cases are always accompanied by a leucocytosis, whether the attack is acute, abortive, mild, or chronic. The character of the leucocytosis is practically the same in all instances, both in adults and in children, and he considered that it is the result mainly of an increase in the number of the polymorphonuclear cells. Nevertheless, he says, a lymphocytosis may be very occasionally observed in infants and in young children. There is a relative decrease of the large mononuclear elements alike in fatal and non-fatal cases, though it is less marked in the chronic type. In acute fatal cases eosinophile corpuscles are always absent, although present in varying degree in all the other groups. Myelocytes were never observed in any of the films examined. Blood platelets were always present in the blood of all the cases examined, sometimes in large numbers. No marked difference was noted in the frequency of occurrence of these elements in the fatal and non-fatal cases respectively. As regards diagnosis, Dr. Dow is of opinion that the leucocytosis is only of value in excluding typhoid fever. From the point of view of diagnosis, he thinks that the absence of eosinophile corpuscles in the acute stage of the disease may be considered of grave significance, but it does not necessarily mean that a fatal issue will immediately ensue, as the case may eventually become chronic.

A communication of considerable interest was made during the year by Dr. D. J. MORGAN in a pamphlet embodying an account of an outbreak of "spotted fever" which occurred in Swansea during 1908. The whole number of cases with which he dealt amounted to 63. It has been generally supposed that infection in cerebro-spinal meningitis is carried by the air and that the germs are inhaled by patients, the throat, nose, and tonsils being the portals of entrance. Dr. MORGAN'S observations do not bear out this supposition. Indeed, he found that cases of apparent direct infection were rare, only three instances occurring in which more than one member of a household suffered. The distribution would seem to be more like that of enteric fever than of immediately contagious diseases, such as scarlet fever or measles. and Dr. Morgan suggests the alimentary canal as the portal of entry, supporting his view on the severity of the abdominal

symptoms encountered, on the occurrence of necrotic areas in the liver, and on the constant enlargement of the abdominal lymphatic glands seen after death. An interesting question with regard to treatment was also raised. Dr. Morgan was struck by the extraordinary divergence in the rate of mortality among cases treated respectively at home and in the isolation hospital at Swansea. Whereas 93 per cent. of the former cases died, in the hospital the death-rate was only 44 per cent. He attributed this remarkable difference to the fact that cases in the hospital were treated by lumbar puncture as a routine measure, whereas when home treatment was carried out this proceeding was sometimes objected to.

Leprosy.

The Second International Scientific Conference on Leprosy held at Bergen in the autumn of this year, afforded a valuable opportunity of taking stock of the present state of opinions held regarding the various aspects of this disease. It is now generally held that Hansen's bacillus is the specific microbe of leprosy. It has, however, been impossible as yet to find a medium in which it can invariably be cultivated outside the human body. The disease is contagious from person to person but the precise way in which contagion takes place has not been demonstrated. The possibility of indirect contagion by fleas, lice, bugs, and the itch parasite cannot be ignored. Some observers claim to have found the specific microbe in the bed bug, and that demodex is sometimes present in the sebaceous follicles of the nose, and that in these same follicles the leprosy bacillus is found, but these observations require corroboration.

Dr. J. M. H. MacLeod emphasised the importance of recognising the possibility of the association of leprosy with other diseases in the same individual and at the same time. Many mistakes have occurred from failure to recognise this possibility, and from regarding every symptom in a leper as being due to the lepra bacillus. The association of leprosy and tuberculosis has been frequently noted in the case of the lungs, and yet there has been a tendency to overlook this possibility elsewhere. Before regarding the caseation with Langerhans's giant cells, which has been described in the spleen, lymphatics, and skin as manifestations of leprosy, Dr. Macleod maintains that it is essential to eliminate by inoculation experiments a mixed infection with tuberculosis.

Sleeping Sickness.

An important step was taken in May last in connexion with the investigation of this disease. A Sleeping Sickness Bureau was established in London, comprising representatives of the Foreign and Colonial Offices and of the Royal Society, to collect and to distribute information respecting this malady. This bureau has already issued some valuable reports edited by Dr. A. W. G. BAGSHAWE, the director of the bureau. In the first the chemo-therapy of trypano. somiasis was dealt with in an exhaustive fashion. It states that practically all patients suffering from sleeping sickness are now treated by atoxyl or some chemically allied substance, either alone or in combination with other drugs. The effect of the administration of atoxyl is to banish the trypanosomes from the blood and the glands. Unfortunately, all the parasites are not killed, for usually a few remain attenuated in virulence and acquire tolerance of the drug. It is therefore necessary to follow up the atoxyl treatment by the use of other trypanocidal drugs, among which may be mentioned mercury and antimony. In the second report the diagnosis of human trypanosomiasis is dealt with, and the exploration of the body fluids, the blood, the gland juice, and the cerebro-spinal fluid, to find the parasite, is discussed in detail. The important subject of gland palpation is likewise considered. Dr. BAGSHAWE also delivered an address

before the Society of Tropical Medicine and Hygiene, limiting himself to the consideration of work carried out during the past 12 months, especially such as had an immediate bearing upon prevention or cure, and made some practical remarks on the administration of the arsanilates. This address was published in our columns on Oct. 23rd.

The report of the German Commission on Sleeping Sickness, appointed in 1906 to proceed to East Africa with a subsidy from Imperial funds to cover the cost of the expedition, was also received. Numerous investigations were made as to whether or not man was the only host of the trypanosoma gambiense. The results were, as a whole, in the negative, and it was concluded that the glossina prefers luman blood for its food, but when this is not available it falls back upon the blood of the crocodile for its nourishment, at least in the region of the Victoria Nyanza.

Diseases of the Heart.

Dr. ALEXANDER MORISON, in delivering an address before the Esculapian Society of London on Cardiac Motion as Revealed by the Vivisection of Disease, raised a number of important physiological and pathological questions. His remarks were founded on the case of a patient who was under his care at the Great Northern Central Hospital suffering from sarcoma of the heart. a condition is rare, and from a clinical point of view there were many features of unusual interest, but Dr. Morison utilised his observations by drawing from them suggestive scientific deductions. For instance, the necropsy revealed the fact that the right side of the heart was so involved in the growth that the circulation had apparently to be carried on almost entirely by the left chamber. The aspiratory and propulsive aid of the right chambers was practically extinguished, and the left side of the heart was acting for a considerable period independently of the right. This in itself is an important observation, for the possibility of this occurring in a heart which has not been bisected is denied by many observers, and the clinical occurrence of hemisystole, or asynchronism of systole in the ventricles while in anatomical union, is denied by those who take this view. One of the most significant features of the clinical aspects of the case was the absence of the usual indications of back pressure, and therefore the blood must have been propelled with sufficient force to insure the nonappearance of congestion or cedema, and considering the extensive invasion of the right side of the heart by the neoplasm the only conclusion to be arrived at was that the left ventricle proved equal to the work thrown upon it.

In delivering the Wightman lecture Dr. GEORGE CARPENTER chose as his subject Congenital Heart Affections, especially in Relation to the Diagnosis of the Various Malformations. He drew attention to the different views which have been held as to the causation of the most prominent symptom—cyanosis. He said that in many cases the explanation is suggested, not that the lungs cannot oxygenate properly, but that they are prevented from dealing with a sufficient proportion of the total quantity of venous blood throughout the body by reason of various defects in the pulmonary region, perhaps combined with weakness of the heart muscle. Cyanosis appeared to depend in some cases not upon defective aeration from defects in the lungs, but rather upon the conformation of the heart, which by reason of faulty construction and physical weakness is placed at a mechanical disadvantage, and is not adapted to deliver a sufficient quantity of venous blood to the lungs to be aerated. Dr. CARPENTER did not think that this would explain all cases, for in some the lungs are not healthy and display considerable microscopical alterations. So wide and so tortuous were the thickened lung capillaries in the case of atresia of the pulmonary artery which he examined that those in the alveoli admitted six or more red corpuscles abreast. Changes such as these, permeating as they did the whole of the lung structure, were not conducive to proper aeration. It would appear, then, that diffuse and not localised structural alterations of the lung tissues are favourable to the production of cyanosis. There are thus two factors in operation—the difficulty of getting the blood to the lungs to be aerated, and the difficulty of aerating the blood when it arrives there should it so happen that the lungs are not in a position to undertake the operation by reason of their structural defects.

Sir T. CLIFFORD ALLBUTT, in opening the discussion on Angina Pectoris at the Section of Medicine of the meeting of the British Medical Association at Belfast, discussed the evidence on which the various theories as to the nature of angina pectoris are based, and explained his own views on the subject. He suggested that the supra-sigmoid portion of the acrta with its investments was the actual site of the change which leads to the disease. Clinical observations had led him to suspect that this region was peculiarly susceptible to changes of blood pressure. He laid special stress upon the investments of the aorta and their involvement in the lesion, and even suggested that the Pacinian bodies which are found in that region might be concerned in the process. He pointed out that recent observations have shown that the pain in intestinal colic and in other forms of visceral pain is not due to the contraction of the non-striped muscle but to the dragging upon the mesenteric or other attachments. He therefore entirely repudiated any suggestion of the cardiac origin of the pain in angina. He believed that there existed morbid susceptibility of the supra-sigmoid region of the aorta and its investments, and the increase of pressure produced a dragging upon these investments, leading to a summation of stimuli which affected the corresponding spinal segment and led to the referred pains so characteristic of this disease. The sudden death he characterised as accidental and due to vagal inhibition, analogous to, and comparable with, the sudden death which occasionally occurs from blows on the testicle, from operations upon the generative organs or upon the root of the lung. In other words, he regarded this special region of the aorta to which he attributed the anginal paroxysm as so sensitive that it might lead to sudden and immediately fatal cardiac arrest from vagal inhibition.

The paper led to an interesting debate in which Sir CLIFFORD ALLBUTT'S views were criticised from several sides, and after the report of the meeting had appeared in THE LANCET the discussion was continued in our correspondence columns, Sir RICHARD DOUGLAS POWELL, Dr. E. H. COLBECK, Dr. NATHAN RAW, and Dr. A. P. BEDDARD all advancing arguments against the attribution of the pain in angina pectoris to diseases in the suprasigmoid aorta. These letters, together with Sir CLIFFORD ALLBUTT'S replies, make an interesting addition to the literature of a muchdebated subject.

Diseases of the Nervous System.

Dr. Ernest Jones delivered an address in April before the Hamilton Medical Society, Ontario, on Modern Progress in Our Knowledge of the Pathology of General Paralysis. He considered that the term "general paralysis," instead of being rather indefinitely applied to a vague group of allied states as was formerly done, must now be restricted to a perfectly definite and sharply marked-off disease having both anatomical and clinical differential features of the most characteristic kind. Reflection on the specific and highly differentiated nature of these changes at once makes it evident that in studying the etiology and pathogenesis of them a similarly specific cause will be found. What that cause is has for

some time been surmised, as the mass of converging evidence drawn from diverse sources and following diverse lines of argument has pointed in only one direction. Dr. Jones indicated that this surmise has within the past few years been most strikingly confirmed by the study of the cerebro-spinal fluid, which showed, on the one hand, that an increase in proteid and a pronounced lymphocytosis occurred in no diseases except syphilis and the affections of tabes and general paralysis that are presumably a sequel of this, and, on the other hand, that highly peculiar substances, the so-called antibodies, are present in every case of general paralysis and in no other affection except syphilis.

On Sept. 18th we published "The Schorstein Lecture" on abscess of the brain in association with pulmonary disease. This lecture consisted of a thesis for the degree of Doctor of Medicine of the University of Oxford as advanced by the late Dr. Schorstein himself. He showed that the chief associations between lung disease and cerebral abscess occur in bronchiectasis and in empyema, which together formed more than three-fourths of all his cases. He also pointed out that cerebral abscess is the second most common cause of death in bronchiectasis

The Vaccine Treatment of Aone.

Dr. ALEXANDER FLEMING drew attention in our columns (April 10th, p. 1035) to the etiology of acne vulgaris and its treatment by vaccines. He first showed the invariable existence of pathogenic bacilli in the comedones; the organisms were cultivated with difficulty on artificial media, but in many cases a pure culture was obtained. Such a culture proved capable of producing a folliculitis on the forearm of a susceptible person. In five days definite pustules appeared, and when the pus from them was examined only the acne bacillus could be seen. Sir ALMROTH WRIGHT showed in 1902 that carefully prepared vaccines derived from the infecting organisms produced a definite beneficial effect. FLEMING'S chief contribution to the subject was the showing that a vaccine prepared from the acne bacillus alone, or in certain cases in combination with a staphylococcus, was capable of effecting a remarkable improvement in the condition. In most cases of acne a stock vaccine of the acne bacillus gave extraordinary results when employed in suitable doses; an excessive dose was followed by a negative phase and the outbreak of a fresh crop of pustules; when the dose was sufficiently reduced improvement followed. In some it appeared to be necessary to prepare a vaccine from the acne bacillus present in the individual patient, but Dr. FLEMING considered such a course to be exceptional.

The etiology of acne vulgaris has for many years been much discussed, but no unanimity has yet been attained. Professor Gilchrist of Baltimore has demonstrated the existence of a bacillus in the early lesions of acne, and in many cases it has been present in a pure culture. The specific character of this bacillus has been denied by many dermatologists in the British Isles, but some recent vaccine experiments have thrown some fresh light on the subject. A few years ago Sir Almroth Wright showed that a staphylococcus vaccine in many cases effected a great improvement in acne when the opsonic index was low; but the staphylococcus vaccine was not successful in all cases, and now Dr. A. Fleming has shown that in such cases a vaccine prepared from the bacillus found in acne is often very effective, while in some others a mixed vaccine is required.

Lupus erythematosus is usually a chronic affection, but from time to time cases occur in which the disease appears in an acute form, and Mr. J. E. R. McDonagh has recorded one of these which he observed in St. Bartholomew's Hospital. The patient was a girl, aged 15 years, who was attacked by the acute form of the disease, and some six months later developed a general peritonitis and purulent

pericarditis followed by death. The pus from both the peritoneum and from the pericardium showed and grew the pneumococcus. Lupus erythematosus is rare in childhood, and for that alone the case deserves publishing, but also the presence of the pneumococcus in this fatal case confirms what is generally recognised, that fatal cases have followed tuberculosis or pneumonia. Most dermatologists are inclined to look upon the disease both in its acute and chronic forms as due to a toxemia.

Mr. RANDAL HERLEY has recorded a case of wound diphtheria occurring in a boy, 18 years of age, who struck his hand on a shovel. Typical diphtheria bacilli were found in the wound which developed. Recovery followed the application of local antiseptic measures and the use of diphtheria antitoxin internally. A swab from the throat was examined with a negative result.

The use of intramuscular injections of insoluble preparations of mercury in syphilis is still under discussion in this country, though elsewhere it is considered of the greatest value. A paper on this subject by Dr. G. PERNET led to an interesting discussion. No one can doubt the efficacy of these injections; the only question is their safety. Much depends on technique, but those who have used them regularly value them greatly.

The Roentgen Ray Treatment of Ringworm.

Soon after the discovery of the Roentgen rays it was found that the rays had the power of causing temporary loss of hair, and when they were employed in ringworm it was found that in certain cases the new hairs which grew after the throwing out of the old hairs were quite free from the disease. Investigation has shown that the X rays have no bactericidal power, and therefore have no direct action on the fungus of ringworm; they merely cause a rapid and complete epilation of all the hairs, whether diseased or healthy, of the part exposed to their influence. The method of actually applying the treatment has now been placed on a firm basis. The essential principle is the accurate adjustment of the dose of the rays so that the desired effect, the removal of the hairs of the area treated, should be produced with unfailing certainty but so that no excess of rays can be administered. In this way the dermatologist can be certain of not producing any permanent alopecia of the scalp and of not causing any X ray burn. The results obtained have been most encouraging.

Lectures of the Year.

We published in THE LANCET as usual the official lectures delivered before the Royal College of Physicians of London. The Lumleian lectures were delivered by Dr. NORMAN MOORE on Rheumatic Fever and Valvular Disease. Hitherto the condition of the joints has been considered as the principal element in rheumatic fever; Dr. NORMAN MOORE, however, insisted that endocarditis is not to be regarded simply as a frequent complication, but as the essential and invariable feature of the affection. He maintained that endocarditis was always present, and that in most cases, but not in all, it produced some permanent alteration in one or more valves. In proof of this assertion he stated that if the heart in a mild case of rheumatic fever is only auscultated at the beginning and end of the disease the sounds may sometimes seem to be unaltered, and it might therefore be assumed that they had been normal throughout, but if the heart were examined daily changes in its sounds would, in his experience, always be discovered. He considered that this fact, taken in conjunction with the evidence of the frequency of definite valvular diseases as a result of rheumatic fever, and of a history of rheumatic fever in cases of valvular disease belonging to the first half of life, justified the belief that those variations in sound might be taken as evidence of the presence of endocarditis, even though

no permanent valvular lesion might ultimately be produced. Dr. A. E. RUSSELL was the Goulstonian lecturer, selecting as his subject "Some Disorders of the Cereoral Circulation and their Clinical Manifestations." He first drew attention to syncopal attacks which might ensue when there was a diminution in the volume of blood passing through the brain, and then proceeded to argue that tne fundamental factor underlying both the ordinary faint and the epileptic fit was cerebral anæmia. He also stated that the difference between the two was one of degree rather than of kind. The Bradshaw lecture was delivered by Dr. JAMES ALEXANDER LINDSAY, who chose as his subject "Darwinism and Medicine." He contended that a general survey of the relation of Darwinism to the science and art of medicine was likely to be salutary in many ways. It would tend to breadth of view, to a philosophic appraisement of the factors which medical men had to deal with, to a recognition of the great underlying laws and secular processes which are related to the art of medicine. Dr. W. S. LAZARUS-BARLOW gave the Croonian lectures on Radioactivity and Carcinoma: an Experimental Inquiry. From the results of his observations he believed that in radioactivity there was a possible isolution of the phenomena of malignant disease. It would suffice to explain the irregular mitoses of malignant new growths; it would explain the lessened formation of pepsin and trypsin in carcinoma, for it had been shown that the activity of these enzymes was much diminished by radio-active influence. It would also explain the curability of some superficial cancers, for in many microbic diseases it had recently been proved that the agent producing a disease might be prepotent in elaborating the remedy. The Milroy lectures, on Disinfection and Disinfectants, were delivered by Dr. R. TANNER HEWLETT; the FitzPatrick lectures, on Greek Medicine in Rome, by Sir T. CLIFFORD ALLBUTT; and Dr. G. H. SAVAGE was the Harveian orator, choosing as his subject "Harvey: Experimental Psychology and Hypnotism.'

SURGERY.

Appendicitis.

Appendicitis has continued through another year to furnish us with surgical developments. In children, very young children, it is not common, though it is difficult to say what is the youngest child on whom an operation has been performed for appendicitis. Two cases recorded in THE LANCET are here deserving of mention. Dr. T. WILSON PARRY has reported the case of a child, 16 months old, who recovered after operation, and a case in a child still younger, just 11 months old, was operated upon by Mr. JOSEPH CUNNING. Cases much younger than this are to be found in the literature. In the cases collected by J. P. C. GRIFFITH was one in which the child was only 6 weeks old, but J. HARRIS operated on a child who was only 41 hours old, and the child recovered. Little has been added towards the solution of the problem of the mode of causation of appendicitis. METCHNIKOFF considers that intestinal worms are often the cause of the disease, but though worms of various kinds have on many occasions been found within the appendix it is generally impossible to show that they have borne any causal relation to the origin of the disease. However, BRUMPT and LECENE have reported a case in which an appendix removed during an attack of acute appendicitis contained a mass of about 50 thread worms, while some of the thread worms were found fixed to the mucous membrane. and one was even found embedded in the wall. In this case there can be no doubt that the worm had penetrated the appendical mucous membrane, and it is almost certain that the worms had given rise to the disease. A case of some importance was reported by Mr. ALBAN H. G. DORAN,

in which a urachal cyst closely simulated an appendicular abscess, and many surgeons have met with cases in which inflamed uterine appendages have resembled, or even been mistaken for, an inflamed appendix.

The discussion as to the best time of operating in appendicitis still goes on, and it cannot be said that at present there is any probability of its being finally settled. Those who have had the most experience of the operation are still inclined to think that it is not essential in every case to perform immediate operation, but it is generally agreed that in a case where any doubt exists as to the mildness of the attack an immediate operation is attended with much less risk than is an expectant treatment. Dr. F. J. SMITH has described a very unusual form of appendicitis in which the only symptoms present were profuse diarrhoa, abdominal pain, and headache, and it was not possible for more than a week to recognise that any inflammation of the appendix was present, but by that time there had occurred a perforative peritonitis which led rapidly to a fatal issue. Mr. G. R. TURNER delivered an important lecture on the desirability of early operation in appendicitis, in which he advocated strongly early operation, and he illustrated his argument by some striking cases. He claimed that in the hands of a surgeon accustomed to abdominal work the early operation is easy and safe. Since 1904 he has removed the appendix in all the cases he has operated upon except five, and four of these five were abscess cases.

Mr. H. S. CLOGG has contributed an article to our columns in which he maintained that in all cases when an appendicular abscess is orened the appendix should always be removed. He described many complications which occurred in the cases where the appendix was left. We concur, on the whole, with Mr. CLOGG's contentions, but it appears to us to be unwise to lay down an absolute rule; much must depend on the exact condition met with by the surgeon in the individual case

Mr. P. H. V. Hammersley recorded a case of appendicitis in a lady in which the attacks of appendical pain were accompanied by hæmaturia and the hæmaturia ceased when the inflamed cystic appendix was removed. Mr. W. Burrough Cosens also reported a case of a boy, three years of age, who was operated upon for acute appendicitis with abscess. A fortnight after the operation he passed much blood with the urine, and the hæmorrhage continued off and on for five weeks. Mr. Albert Carless has met with this association of appendicitis with hæmaturia on several occasions. It is difficult to explain the connexion between the two conditions, but the report of several cases in which the two have coexisted in the same patient points to the probability that their concurrence was not merely a coincidence.

Appendicostomy.

In opposition to the general tendency to remove the appendix freely even when it does not exhibit any manifestations of disease, as has been recommended by some surgeons, there are a few surgeons who consider that the appendix may have some important functions as yet unknown to us, and therefore they advise that its removal should not be performed except when disease renders it necessary. There are others, again, who consider that in addition to any unknown functions which nature may have conferred upon the vermiform appendix it possesses possibilities of value which can be utilised by the surgeon. Mr. C. B. KEETLEY, whose loss we have so recently to deplore, was one of the most strenuous advocates of the potential value of the appendix, and we published in THE LANCET a characteristic paper from him which he read before the Surgery Section of the Royal Society of Medicine. In this he drew attention to the fact that he had demonstrated the value of the operation of \

appendicostomy in the treatment of cases of inveterate constipation, for the opening so formed could be utilised as a channel by which drugs could be introduced into the large bowel. In this paper also he showed that the operation of appendicostomy was of equal value in many other morbid conditions of the large intestine and also of the lower part of the ileum. The operation has been extensively employed, especially in the United States of America, in the treatment of dysentery and other affections of the colon; its value also as a means of administering nutritive injections in place of enemata must not be forgotten. In this country the operation for appendicostomy has not been received with enthusiasm, and therefore at the present time it cannot be said that we have sufficient material on which to base a decided opinion as to the value of the operation. Those who have had most experience of it agree in stating that the operation itself is simple and free from troublesome complications, though few go so far as Mr. KEETLEY in suggesting that appendicostomy should be performed even in cases of acute inflammation of the appendix. Mr. GEORGE HEATON has recorded a case in which he did appendicostomy for membranous colitis in a woman, aged 35 years. with satisfactory results.

Vesico-appendical Fistula.

Dr. R. CADWALLADER has recorded a very rare condition—a permanent fistula between the appendix and the bladder, so that some of the contents of the bowel were able to find their way into the bladder. He operated on the case, and recovery followed. Dr. W. W. KEEN had previously reported a similar case.

The Appendix in a Hernial Sac.

Mr. A. B. GRIFFITH has drawn attention to a rare condition. The patient, who was under the care of Mr. E. W. ROUGHTON, had a left inguinal hernia. Mr. GRIFFITH performed a radical cure, and when he opened the sac it was found to contain the vermiform appendix firmly adherent to the inner wall. Inguinal hernia on the right side not rarely contains the appendix, but only a few cases have been recorded in which it has been found in a left inguinal hernia.

Mr. OWEN RICHARDS of Cairo has also recorded two cases of the presence of an appendix in a left inguinal hernia, but in neither did the appendix form the sole occupant of the hernial sac.

Mr. T. H. KELLOCK has reported a case of a child two years and four months old, in whom the hernial sac of a right inguinal hernia was found to contain an incarcerated appendix, and in the appendix was a pin. Curiously no suppuration was caused, though the wall of the appendix and the wall of the hernial sac had both been perforated by the pin.

Herniotomy at the Extremes of Life.

Mr. H. W. Webber of Plymouth has reported two cases of hernia of some interest on account of the age of the patients. One patient was a man, 93 years old, who suffered from strangulated inguinal hernia. The operation was performed under local anæsthesia and recovery followed, though some weeks later the patient developed a cough and died. Mr. Webber's other case was even more interesting, for it was a case of umbilical hernia in a child two hours old, or perhaps it might be more correctly described as a case of partial ectopia viscerum. Several other abnormalities of development were present, for on each side there was a supernumerary auricle and on each hand an extra digit, while the palate was cleft. The bowel was returned and the umbilical opening was closed, but the child died two days later.

A few years ago we reported a case of a child, six weeks old, who was successfully operated upon for strangulated inguinal hernia, but as the child was only a seven months child the operation really took place a fortnight before the child should have been born. We think that in all probability this is the earliest case of a successful treatment of a strangulated hernia.

Epiploitis after Radical Cure of Hernia.

Now a-days we are accustomed to absolutely uneventful convalescence after operations for radical cure of hernia, but occasionally complications occur which demonstrate the necessity for unceasing vigilance in the performance of this common operation. Dr. C. GREENE CUMSTON has described a case in which epiploitis followed a radical cure. The patient was 24 years old, and his right inguinal hernia contained only a large mass of omentum. This was resected and tied with kangaroo tendon. On the day after the operation the abdomen was distended and the patient complained of pain. The temperature did not rise till the ninth day, when it was 102° F., and the abdomen became still more distended. A swelling was felt on the right side, reaching from the margin of the ribs to the iliac fossa; constipation became obstinate, and epiploitis was diagnosed. Ice bags were placed on the abdomen and a pill containing 2 centigrammes of colloid silver was given four times a day. The temperature came down slowly, and seven weeks after the operation the patient was discharged in perfect health. There can be no doubt that this epiploitis was septic in origin, but the infection was mild and did not go on to suppuration.

Hornia through the Foramen of Winslow.

Hernia through the foramen of Winslow is fortunately rare, but cases are described from time to time. Mr. WALTER H. HAW of Knysna, Cape Colony, has described a case in a little coloured boy, five years old, who was brought to him in a dying condition; in fact, he only lived half an hour. At the necropsy it was found that the cæcum, the appendix, and part of the ileum had passed through the foramen of Winslow; reduction was impossible until the small omentum had been cut through. It is worthy of mention that 53 round worms were removed from the cæcum and appendix; the latter was much dilated and of the diameter of the thumb.

Hernia of the Ilio-pelvio Colon.

Mr. H. BETHAM ROBINSON delivered an interesting clinical lecture on Hernia of the Ilio-pelvic Colon; he reported 11 cases of this condition, illustrating its several varieties, and he pointed out the great importance to the surgeon of the arrangement of the peritoneum over both the iliac and the pelvic colons, and also the great differences that may result from variations in the length and course of the iliac colon.

Radical Cure of Hernia in Childhood.

Mr. WILLMOTT EVANS contributed an article in which he maintained that in children suffering from inguinal hernia mere removal of the sac was all that was needed in performing a radical cure, and that recurrence never occurred.

Volvulus in Connexion with Hernia.

Mr. J. F. Dobson of Leeds recorded two cases of volvulus in connexion with hernia, and Mr. R. Lawford Knaggs of Leeds recorded four; in some of these cases the twist occurred within the hernial sac and was readily recognised, but in others the rotation took place within the abdominal .cavity, and then the condition was shown by the fact that gentle traction on the bowel withdrew from the abdomen intestine as deeply congested as that previously herniated, while it was seen that the cause of the congestion lay higher than the neck of the sac. These cases of volvulus in connexion with hernia are rare, and the cause may be readily overlooked unless the surgeon is aware of the condition.

Mr. WILLIAM BILLINGTON of Birmingham described a remarkable case in which the whole of the small intestive. | had operated within nine months; of these, 10 affected the

together with the cæcum and ascending colon, had undergone rotation, so that the swollen cæcum formed a palpable swelling on the left side. The abdomen was opened six days after the commencement of symptoms, and after emptying the excum through an opening made into it, it was possible to replace the bowel in its original position, and recovery followed. Such an extensive twisting of the bowel can only be possible where the mesentery is abnormally long.

Resection of Bowel.

Mr. W. Sampson Handley recorded a case of extensive resection of gangrenous ileum. The patient was a woman, 29 years old, and she suffered from severe abdominal pain, with symptoms of obstruction. When the abdomen was opened it was found that a mass of the ileum had passed through a hole in the mesentery of the ileum, whereby it had become strangulated. The gangrenous portion of the ileum, 33 inches in length, was resected close to the ileo-cæcal valve and the ileum was implanted into the cæcum. An uninterrupted recovery followed. Mr. G. P. NEWBOLT of Birmingham read a paper at the Belfast meeting of the British Medical Association on 24 cases in which he had resected bowel, and the paper led to a valuable discussion on the methods to be employed in resection of intestine. Opinions were fairly divided between resecting the gangrenous bowel in strangulated hernia at once and postponing the restoration of the continuity of the intestine to a later stage.

Mr. H. M. RIGBY described two cases, in each of which a double resection of intestine was ultimately required. Recovery ensued in both cases.

Duodenal Fistula and Perforation: Pylorectomy.

Mr. LAWFORD KNAGGS of Leeds has described a case of duodenal fistula which he cured by operation. The patient, a girl 17 years old, developed an abscess on the right side of the abdomen. When it was opened about an ounce of pus was evacuated, and it was thought that it had formed under the sheath of the psoas muscle. A drainage-tube was left in and it was later found that the discharge had a peculiar odour, but there was no bile or fæces. The fistula contracted, but still much discharge continued, and charcoal was found on the dressings about four hours after being taken by the mouth. She left the hospital and was readmitted three months later in the same condition. The abdomen was opened and very many adhesions were seen in the neighbourhood of the duodenum, and a depression was found on its posterior wall, probably an ulcer. A posterior gastroenterostomy was performed, and then the pylorus was enfolded by two rows of Lembert sutures parallel to its long axis, so as to convert the pyloric end of the stomach into a solid roll. After the operation the sour odour disappeared at once from the discharge, and no more particles of food were seen. The sinus did not close finally till 18 months later.

Hepato-omental Bands Constricting Stomach.

Mr. GEORGE A. HAWKINS-AMBLER of Liverpool has recorded a case in which adhesions between the great omentum and the liver constricted the stomach, so as to give rise to severe abdominal pain occurring sometimes before and sometimes three or four hours after meals. In hospital she suffered but little, yet the pain returned when she resumed work. At the operation the bands of adhesion were divided between catgut ligatures, and some other bands behind and below the stomach were also severed. No sign of disease could be detected in the stomach. Recovery was rapid and complete.

Perforation of Stomach and Duodenum.

Mr. James Grant Andrew of Glasgow described 13 cases of perforation of the stomach and of the duodenum on which he stomach and 3 the duodenum. Mr. GRANT ANDREW discussed the symptoms and signs present in his cases, and the mode of operation performed. Of the 10 cases of gastric perforation, 6 recovered, but all the duodenal cases died. The series is undoubtedly of interest and the discussion of the details of the cases is of value.

Pulorectomu.

Mr. Sinclair White of Sheffield has recorded an unusual sequel to pylorectomy. The operation was performed for malignant disease and the patient did well for three weeks, but at the end of that time severe abdominal pain appeared with vomiting; his general condition was so bad that the abdomen was opene dagain through the healed wound; several quarts of clear fluid escaped, and on bacteriological examinano evidence of the presence of organisms in it was obtained. The parts concerned in the operation were found to be soundly healed and there was no evidence of peritonitis, but about eight feet of the upper end of the small gut and its mesentery were of a bright pink colour. No cause for it could be found. The abdomen was drained suprapubically for a few days and the patient recovered. It is difficult to suggest any simple explanation of this curious condition.

Intussusception.

Intussusception of the colon simulating a simple prolapse of the rectum is rare, and therefore a case exhibiting this condition described by Mr. ALEXANDER DON of Dundee was of especial interest. The patient was a woman, 44 years old, who after a purgative felt a mass protruding from the anus while at stool. When seen the next day a sausage-shaped swelling nearly 10 inches long protruded from the anus, and at its apex was a polypoid mass. The condition was considered to be a prolapse of the bowel, and after tying and removing the polypoid mass Mr. Don attempted to return the bowel; as this attempt was unsuccessful the abdomen was opened and it was found that the mass consisted wholly of the colon. The intussusception was readily reduced, but as the affected bowel and its mesentery were of doubtful vitality they were fixed outside the abdomen, and on the following day the bowel was opened and the necrotic mass was removed. At a subsequent operation the continuity of the bowel was restored. The polypoid growth was found to be a simple villous papilloma.

Mr. HAROLD STIFF has reported a case in which a carcinoma of the excum caused intussusception; the growth was removed with part of the excum through an incision in the transverse colon and an uneventful recovery followed.

Surgery of Gall-bladder and Pancreas.

Mr. HUGH LETT has described two unusual conditions of the gall-bladder. In one, a woman, aged 72 years, had severe pain in the right hypochondrium, and a rounded swelling could be felt in the region of the gall-bladder. When the abdomen was opened it was found that the swelling was a distended gall-bladder, fixed by recent adhesions. The gall-bladder was tapped and a black fluid composed of altered blood and a little bile was drawn off; it was then discovered that the gall-bladder had been rotated so as to twist the cystic duct. There were four and a half turns from left to right. The gall-bladder was excised; the patient died 12 hours after the operation. In the second case a woman, aged 37 years, had three gall-stones removed, and the gall-bladder was drained by Mr. JONATHAN HUTCHINSON, but 21 months later pain was felt in the right hypochondrium, where there was a rounded swelling. At the operation it was found that carcinoma had appeared in the gall-bladder; this was removed and recovery followed.

Abscess of the Pancreas.

Mr. SETON S. PRINGLE of Dublin has reported a case of great interest in which an abscess of the pancreas was

opened. The patient, a man, aged 46 years, for 10 days had abdominal pain, gradually growing worse, and ultimately becoming acute; he was then admitted into hospital. The upper two-thirds of the abdomen were dull, the dulness extending into the flanks. At the operation a large abscess was found at the site of thepancreas. This was drained, but the patient died 12 days later. Very few cases have been published of operations for abscess of the pancreas, and the death-rate is very high; 5 deaths occurred in 14 cases according to MAYO ROBSON'S statistics.

Foreign Bodies in the Stomach.

Mr. BILTON POLLARD has described an ingenious method which he has devised for the removal of foreign bodies from the stomach without incising the stomach wall. A girl, aged 15 years, swallowed a two-shilling-piece, which lodged in the stomach. The abdomen was opened and the coin seized by the operator between his finger and thumb. An assistant passed a special pair of flexible forceps by the mouth into the stomach; the coin was adjusted in the grip of the forceps, care being taken to avoid the inclusion of the mucous membrane; and the assistant then withdrew the forceps with the coin. The forceps resembles Toynbee's ear forceps, the blades springing apart when uncontrolled. Mr. G. P. NEWBOLT and Mr. R. A. Jones have recorded a case of hair-ball in the stomach in a woman, 22 years old, who had severe dyspeptic symptoms. There was a history of swallowing hair and the diagnosis was confirmed by operation, a mass of hair 7 inches long and 3+ inches broad being removed. Recovery followed after a severe attack of gastritis.

1leosigmoidostomy.

Mr. C. W. Mansell Moullin was the first to perform ileosigmoidostomy for the relief of inveterate constipation, for his earliest case was in 1900. He has now performed the operation seven times, and in all the cases the relief has been very great; there was no mortality. He considers it essential that the new opening should be free, not less than 4 inches in length, and the ileum must not be divided; he holds that division of the ileum means breaking the continuity of peristalsis and leaving the excum and the greater, part of the colon as a blind receptacle, without any possibility of any stimulus reaching it through the bowel on the proximal side.

Colon.

Mr. CHARLES RYALL has devised a new method of attempting to secure sphincteric control after colostomy. His method consists in passing the upper segment of the colon through loops of muscle fibres of the rectus, formed by separating bundles of fibres, or double loops can be made on each side. In a case of acute ulcerative colitis in a man, aged 40 years, Mr. Heaton performed a execostomy so as to divert the fæces from the inflamed colon. The large bowel was irrigated daily with quantities of warm boric lotion, and ten days later a weak solution of silver nitrate was employed instead. The colitis subsided and the opening into the execum was closed three months later.

Torsion of the Spleen and Spleneotomy.

We have published two cases of acute torsion of the splenic pedicle. In one, under Dr. IAN MACDONALD and Dr. W. A. MACKAY of Huelva, the patient was a multipara who had had malaria, and attacks of severe abdominal pain occurred; a diagnosis of moveable kidney was made. As the severity of the symptoms increased a laparotomy was performed and a spleen with two twists of its pedicle was found and removed. In spite of an intercurrent attack of pneumonia the patient recovered. The other case was under the care of Mr. Peter Paterson of Glasgow, and the patient was a girl, 16 years of age, who had had attacks of abdominal pain for five months previously, and in the abdomen a large

smooth rounded tumour was felt. When the abdomen was opened it was found that the pedicle of the spleen had undergone four complete twists, and the vessels were completely thrombosed. The spleen was removed successfully.

Splenectomy for Ruptured Spleen.

Cases of removal of a ruptured spleen are by no means rare, but two recorded during the year are worthy of note. In one under Mr. D'ARCY POWER, and reported by Mr. T. S. LUKIS, a boy, 7 years old, was said to have had a wheel of a wagon weighing 2 tons pass over the abdomen; the child was much collapsed at the time, and the operation was not performed till 42 hours after the injury, when the spleen was found badly ruptured, but all hæmorrhage had stopped Splenectomy was performed and the child recovered. In the other case Dr. J. CRAWFURD RENTON of Glasgow removed the spleen from a boy, 14 years old, who had been run over by a van. The boy was not admitted to the hospital till 24 hours after the injury. The extreme anæmia of the patient, the restlessness, the quick pulse, and the rigidity over the left half of the abdomen all pointed to some severe intra-abdominal injury with hæmorrhage. abdomen was opened and it was seen to be full of blood. The spleen was found to be ruptured, and it was removed after ligature of its pedicle. Later some sterile fluid was evacuated from the abdomen and also from the right pleura, and later still a pneumococcal empyema developed on the same side. After the pus was let out complete recovery followed. In Dr. RENTON'S case differential blood counts were made at intervals for more than a year. The most striking feature was the gradual increase in the relative number of the lymphocytes, and even a year after the accident they were still increasing.

Esophagoscopy.

The value of direct esophagoscopy has seldom been more strikingly demonstrated than in a case under the care of Mr. Herbert Tilley. An infant only four days old had swallowed the teat of a "comforter," stuffed with cotton-wool. Mr. Tilley was able by means of a small bronchoscope to remove the wool and also the teat from the esophagus with a slender pair of laryngeal forceps. The child was none the worse for the exploration and he was able to take the breast a few hours later.

Surgery of the Blood-vessels.

The surgery of the blood-vessels is advancing, and it is now acknowledged that suture of a wounded vessel of any great size is the best treatment. A novel and daring operation has been performed by Dr. J. P. MURPHY of Chicago. A woman, 41 years of age, developed thrombosis of the left iliac artery, which was giving rise to dry gangrene of the limb. Dr. MURPHY exposed the femoral artery immediately below Poupart's ligament and opened it; it was found to be completely thrombosed. With delicate forceps a bifurcated clot 12 inches long was withdrawn from below upwards, and then fresh arterial blood came from below. A finger controlled this hæmorrhage and Dr. MURPHY withdrew some clot from the proximal side, but no blood flowed, and several instruments were passed in vain; but at length bright blood flowed. The wound in the artery was then sutured and the circulation was in part re-established. Four days later amputation was performed 4 inches below Poupart's ligament and the flap survived. Mr. Donald J. Armour and Mr. E. ARCHIBALD SMITH have recorded a remarkable attempt to prevent the spread of gangrene in the leg of a man 69 years old. The femoral vessels were exposed a little below the apex of Scarpa's triangle, and they were cut across and the upper end of the artery was sutured to the lower end of the vein, and similarly the lower end of the artery was

joined to the upper end of the vein; further, the internal saphenous vein was tied in order to prevent "short-circuiting." The operation was done under lumbar anæsthesia, and the patient bore it well. Unfortunately gangrene spread upwards to the thigh, and a fortnight after the anastomosis the leg was amputated a hand's breadth above the knee-joint.

Prevention of Hamorrhage in Amputation of the Hip.

At the present time the chief danger in amputation of the hip is from hæmorrhage, and the method introduced by McBurney of New York is probably the best mode of preventing the loss of blood. It consists in opening the abdomen and compressing digitally the common iliac vessels while the limb is being removed. We have published two cases of the employment of this method. In one Mr. E. W. ROUGHTON was the operator and in the other Mr. T. P. LEGG, and in both a successful result was obtained.

Anastomosis of Nerves.

Mr. C. A. BALLANCE has recorded a case of facial palsy treated by facio-hypoglossal anastomosis, in which a junction was also made between the spinal accessory and the distal segment of the divided hypoglossal nerve in order to prevent permanent lingual paralysis and atrophy. The patient was a woman, 25 years old, and the facial palsy was due to unhealed disease of the temporal bone. The double union was made as mentioned, and recovery was very satisfactory.

Mr. A. H. Tubby contributed a valuable paper on the Treatment of Distal Paralysis by Nerve Anastomosis to the International Medical Congress at Budapest, in which he described the eight cases in which he had operated; two of these were for paralysis due to traumatism, and six were for infantile paralysis. In only two of the whole series could it be said that no clinical signs of regeneration were apparent even after four years, but in one of these operative exploration showed that the external popliteal nerve was being regenerated centrifugally.

OBSTETRICS AND GYNÆCOLOGY.

The Modern Position of Obstetric Medicine.

In his address in Obstetrics at the British Medical Association meeting in Belfast Sir JOHN BYERS considered the modern position of obstetric medicine and surgery and suggested the lines of advance along which progress may be expected in the future. After calling attention to the gradual but steady diminution in the morbidity rate which at the present time is taking place in all lying-in hospitals, Sir John Byers pointed out that this result has been obtained by a recognition of the fact that labour is a natural process—in the great majority of cases requiring no interference, by the thorough application of the most minute surgical cleanliness, and by the observance of CREDE'S teaching that even the simplest internal manipulation may cause septic infection. The death-rate from the septicæmia of childbirth is still one of appalling magnitude when we consider the results obtained in lying-in hospitals, but that there is hope for the future may be gained from a perusal of the figures quoted by Sir John Byers. In indicating the lines of possible and probable progress he laid stress on the more thorough practical training of students and pupil midwives, the need for studying the public health aspect of obstetric medicine, and the importance of the intimate association of the physiological chemist and the pathologist with the obstetric physician.

The Centenary of Ovariotomy.

The present year is one of much interest to gynæcologists, since it marks the centenary of the first operation for the removal of a cyst of the ovary performed by EPHRAIM McDowell in December, 1809. The occasion was celebrated

especially at the annual meeting of the American Gynecological Society in New York, at which the President, Dr. J. RIDDLE GOFFE, delivered an eloquent address on the Father of Ovariotomy. As Dr. Goffe pointed out, McDowell was not only the pioneer of ovariotomy, but he performed the operation with a technique which but for the absence of aseptic precautions differed little from that employed by most surgeons at the present day. Of the 13 cases operated upon by McDowell, 5 died and no less than 8 recovered. He made a short incision for exploratory purposes, followed by a long median or extramedian incision, in both cases avoiding the umbilicus; he practised transfixion of the pedicle, and he sewed up the abdominal wall with interrupted sutures. To an American, too, belongs the honour of being the second surgeon in the world to perform the operation of ovariotomy; this was Dr. NATHAN SMITH, professor of surgery at Yale University, who removed an ovarian cyst successfully on July 5th, 1821. The beneficent results of the pioneer operation of the American surgeon are almost impossible to estimate. PEASLEE calculated that in the 30 years preceding the year 1870, 30,000 years of life had been saved to women by the performance of this operation, and if this was so up to that date what must be the number of years of life saved since then as a result of the thousands of ovariotomies which have been performed successfully all over the world?

Scopolamine-Morphine Narcosis during Labour.

Two important papers on this subject have appeared during the past year, one by Sir HALLIDAY CROOM and one read at the International Medical Congress by Professor KRÖNIG. The latter, in considering the utility of scopolamine for producing drowsiness during labour, said that in women who were sensitive or of nervous temperament or neurasthenic a tedious and painful labour often brought about long-continued and not unimportant states of nervous exhaustion. In those cases it was desirable to reduce the woman's suffering to a minimum by a method which was not injurious to either her or the child. Since STEIRBUCHEL had recommended the scopolamine-morphine treatment for this purpose Dr. Gauss has been working in Dr. Krönig's clinic with specially introduced systems of testing the state of consciousness at any given time, and has greatly improved the methods for the production of the narcosis in question. On the basis of a clinical material amounting at the present time to 2000 deliveries it might be stated that the production of drowsiness by scopolamine was free from darger to both mother and child, and accomplished the object in view by either completely abolishing or else reducing to a minimum the pains of parturition. Sir HALLIDAY CROOM read a paper before the Edinburgh Obstetrical Society on his experience of scopolaminemorphine narcosis during labour. He gave the results of its action on 63 cases in private and in hospital. He believed the best dose was 1-100th grain of scopolamine and 1-6th grain of morphine, and he usually administered it towards the end of the first stage of labour when the pains were coming regularly every few minutes. Occasionally a second dose of scopolamine of 1-200th grain was necessary, but he found it advisable not to repeat the morphine. With these doses the pain of the uterine contractions was markedly diminished and in some cases abolished altogether, and the patients slept soundly in the intervals between the pains and after the completion of labour. Further, the memory of the pains was in most cases strikingly blurred. and many of the patients awoke with no recollection whatever of them. He had found no ill-effects from the drugs upon the mother except a little tendency to postpartum hæmorrhage, but occasionally the children were born

sleepy and required to be revived. In no case was the child's condition serious and none were stillborn. He believed that the treatment was most suited for nervous primiparæ, and particularly in private practice, but emphasised the necessity of using the drug in a freshly prepared form. In the discussion on KRÖNIG's paper GAUSS admitted that investigations made by him with HOLZBACH proved that the secretions, and especially the urine, of the children born after such narcosis contained scopolamine. The children are often born in a condition of oligopnœa with some pallor, and lie quite still with limbs which, though relaxed, respond to stimulation. The oligopnœa rapidly passes off, and this method of inducing narcosis does not, according to him, increase the number of stillbirths nor the infantile mortality during the early days or during the first year of life. The method is not one to be used indiscriminately, and the patients should be under the care of, and closely watched by, a competent physician.

Rupture of the Uterus.

The treatment of cases of rupture of the uterus is still a subject upon which there is a great deal of difference of opinion among obstetric physicians. An important paper was read at the June meeting of the Obstetrical Section of the Royal Society of Medicine by Dr. T. W. EDEN in which he recorded three cases of rupture of the uterus treated by supravaginal abdominal hysterectomy, of which two recovered. He advised that all cases of severe rupture should be treated by abdominal section and removal of the uterus, because (1) it is the only certain way of controlling hæmorrhage; (2) the uterus has frequently been infected previous to the operation; (3) if the uterus is left and the patient recovers the risk of repeated rupture in a subsequent pregnancy is high. Laparotomy and suture of the rent had been shown to yield a higher mortality than hysterectomy, and, for the other reasons stated, was not to be recommended. In cases of extreme urgency it might be wiser, after opening the abdomen to control hæmorrhage. simply to pack the rent from above into the vagina and to remove the uterus a day or two later by the vaginal route. At the same meeting Dr. A. L. H. SMITH recorded the results of 10 cases of rupture of the uterus occurring among 10.989 deliveries at the General Lying in Hospital during the last 20 years. Of these nine died and only one recovered. Most of the speakers who took part in the discussion held the view that no hard-and-fast rules could be laid down for the treatment of these cases, but that each one must be treated on its merits. When possible no doubt hysterectomy is the ideal treatment for this class of case, but, unfortunately, in the majority of instances the patient is not in a condition to bear either vaginal or abdominal hysterectomy.

A very remarkable case of rupture of the uterus by contrecoup in a woman not in labour was recorded by Dr. JOHN PHILLIPS. The woman, a healthy VI.-para, when seven months pregnant fell some 12 to 14 feet on to her buttocks. 10 days after the accident abdominal section was performed and a ragged tear was found in the anterior wall of the uterus in its lower portion, while the fœtus together with nearly the whole of the placenta and membranes had passed through the cleft and were lying free in the abdominal cavity. These were removed and the edges of the tear pared and sutured. The patient made a good recovery and 10 months later was very well. The interesting features in the case are two: the fact that the patient did not develop any peritonitis and the method of production of the rupture. No doubt the condition was caused, as Dr. PHILLIPS suggests, by the impact of the fœtus against the anterior wall of the uterus.

¹ THE LANCET, May 8th, p. 1320.

The Treatment of Contracted Pelves.

With the gradual lowering of the death-rate after the operation of classical Cæsarean section, together with the development of pubiotomy and the introduction of suprasymphyseal Cæsarean section, our methods of treating cases of contracted pelves are gradually, but surely, undergoing a change. At the same time it must be remembered that increasing experience is again bringing to the front the teaching of some of the greatest masters of obstetrics. teaching which of late years there has been a great tendency to forget-namely, the extreme importance of allowing, whenever possible, spontaneous labour to occur in a case of contracted pelvis. In a most interesting paper read before the Glasgow Obstetrical and Gynæcological Society Professor F. SCHAUTA laid great stress upon this point, and showed that in his clinic, considering labours at full term only, nearly 80 per cent. in cases of contracted pelves ended spontaneously. Not only did they end spontaneously but this termination gave better results for the mother than any other, and better results for the child as compared with any other method of treatment, with the exception of Cæsarean section. In cases of contracted pelves where labour took place in a lying-in hospital under the best possible surroundings he recommended the following lines of treatment. With a conjugate of above 8 centimetres (3) inches) there is a possibility of spontaneous delivery and therefore expectant treatment should be adopted. In cases with a conjugate under 8 centimetres (3) inches) Cæsarean section should be performed, and in cases with a conjugate of 8-84 centimetres (31-32 inches) hebosteotomy is to be considered. This operation with a conjugate of 8-81 centimetres (31-32 inches) would be an alternative to spontaneous labour, with a conjugate of 71-81 centimetres (3-31 inches) an alternative to Cæsarean section. The choice would be deter. mined by the size of the head, the character of the labour pains, and the general condition of the patient. These methods should be regarded as typical, and all other methods, such as the induction of premature labour, craniotomy, version, and the application of forceps to the head above the brim, as atypical, and only to be undertaken in special circumstances. These conclusions will be received with some hesitation by many English practitioners, but they are interesting as the matured views of an obstetrician of great experience and of much eminence. and as indicating the trend of modern treatment in these cases. Even in this country at the present day the indications for Cæsarean section are becoming wider and wider, and while hebosteotomy has made but little headway obstetricians are returning to the teaching of SMELLIE and HUNTER, and are at last abandoning the dangerous method of applying forceps to the head above the brim. induction of premature labour still holds its own in England, but there are not lacking signs that among the more enterprising Scotch and Irish schools of obstetricians it is losing the favour it once had in the treatment of contracted pelves. We may well anticipate for the future the more widespread adoption of hebosteotomy and Cæsarean section, the abandonment of craniotomy, except on the dead child, and the much more frequent performance of Cæsarean section when it can be performed as an operation of election.

Suprasymphyseal Casarean Section.

This operation, introduced by FRANK and modified by SELLHEIM, is still upon its trial, but seems likely to take a recognised place as a method of performing Cæsarean section in the future. It aims at exposing the lower uterine segment by an incision above the symphysis pubis without opening the peritoneal cavity, or with the suture of the peritoneum so as to shut the symphysis peritoneum so as to shut the symphysis peritoneum so as to shut the last 200 cases the mortality had fallen to 10 per cent., and Wertheim hoped in the future for an absolute cure of 30 per cent. It must be borne in mind, however, that some authorities still maintain that an extended vaginal hysterectomy will give equally good results in early cases, but it is the experience of all operators that early cases often

off the peritoneal cavity. The extraction of the child follows by a longitudinal section through the lower uterine segment. The operation possesses a special value in cases where the contents of the uterus are already infected, and in doubtful cases where the classical operation is contra-indicated can no doubt be performed with much less risk.

Histology of Fibro-myomata of the Uterus.

An interesting paper upon this subject was published during the past year by Dr. FLORENCE E. WILLEY, who, as the result of the examination of a large number of small fibro-myomata of the uterus, comes to the conclusion that these tumours arise as irregular patches of proliferation of muscle cells of the uterine parenchyma, which have no special relation to the vascular system. The cause of this proliferation is unknown, but the absence of growing tumours before puberty and after the menopause suggests some relation to the activity of the sexual organs. The view held by most writers that fibro-myomata originate by proliferation of the cells forming the coats of arteries or capillaries, and that the muscle fibres are arranged concentrically around a central vessel, is not a correct one, and Dr. WILLEY found no evidence to support it.

Chorion-epithelioma of the Ovary.

A very interesting example of this condition has been recorded by Dr. J. S. FAIRBAIRN, and in his paper he mentions two other similar cases from DOEDERLEIN'S clinic. The cases all occurred in multiparous women in the childbearing period of life and without any history of a preceding cystic mole. There was some disturbance of the menstrual function, but abdominal pain was the chief symptom. The tumours presented the characteristic appearances, both macroscopically and microscopically, of chorion-epithelioma, and there was no evidence of any teratomatous structures or of any immediately antecedent gestation. In one case there were metastases in the vagina, and these in a second case were in the other ovary, but there were not any in the case described by Dr. FAIRBAIRN. The entire absence of any evidence of a preceding ovarian gestation or of a teratoma of the ovary leads Dr. FAIRBAIRN to attribute the origin of these very rare tumours to the deportation of villi from a normal placenta to the ovary and the subsequent development of a chorion-epithelioma in this situation.

The Treatment of Operable Caroinoma of the Cervix.

The best operation to perform for this disease is still a matter upon which a good deal of difference of opinion exists among gynæcologists. In this country the extended abdominal operation with which the name of Professor WERTHEIM is usually associated is making considerable headway, and as it appears to be based on sound surgical principles and to give the best ultimate results, without doubt it will be practised more and more in the future. In inexperienced hands the immediate mortality is still very high, but this has been the case in the evolution of most extensive operations, and not so many years ago the extended operation for the removal of a cancerous tumour of the breast had a mortality which at the present day has been reduced almost to the vanishing point. The latest results published by WERTHEIM are most encouraging. He has now operated by his method in 487 cases, of which in 200 the operations had been performed more than five years ago. In these 200 cases there had been a mortality of 24.5 per cent. and an absolute cure of 19.3 per cent. In the last 200 cases the mortality had fallen to 10 per cent., though the operability had risen to nearly 60 per cent., and WERTHEIM hoped in the future for an absolute cure of 30 per cent. It must be borne in mind, however, that some authorities still maintain that an extended vaginal hysterectomy will give equally good results in early cases.

remain without recurrence no matter what operation is performed, and no single operator has so far equalled WERTHEIM'S percentage of absolute cure.

Physiology of the Oraries and Uterus. The Growth of the Ovaries after Double Oöphorectomy.

In a paper on conservative surgery in regard to these organs Dr. E. W. SCOTT CARMICHAEL described the results of some experiments carried out along with Dr. F. H. A. MARSHALL. There was a general agreement as to the ovary being an organ of internal secretion; its functional activity was, however, supposed to depend on the presence of the uterus, and a substance called "uterin" had been spoken of as maintaining the uterus in functional activity without the presence of ovarian tissue. Dr. CARMICHAEL and Dr. MARSHALL removed the entire uterus in four very young rabbits, which were allowed to attain full growth, and when they were ultimately killed it was found that the ovaries had developed normally. These experiments therefore showed that the growth and development of the ovaries were not dependent on the presence of the uterus, the results being in direct contradiction to those of ZWEIFEL, ABEL, and MENDL and BURGER. It followed from this that the removal of the uterus along with diseased ovaries was a very different matter from removal of the ovaries with a diseased uterus. Conservative operations on the uterus, analogous to the conservative treatment of ovarian tissue, were consequently unnecessary save where safety to the patient demanded them.

In a paper read before the Pathological Section of the Royal Society of Medicine Mr. S. G. SHATTOCK demonstrated that in the young rabbit when double oöphorectomy was performed without the use of ligatures and without disturbing the remainder of the generative organs in any way the result was to produce overgrowth of the uteri (which, in the rabbit, are two) as compared with those of an animal of similar size, whether it had been impregnated or not. He said that gynæcologists were divided in opinion as to the predominant influence of the human ovary on the growth of the other reproductive organs, but his individual opinion was that a fully developed condition of the uterus was an indication that one or both ovaries had at some time or other been in a state of functional activity. He believed that in both sexes the external sexual characters were due to the formation of an internal secretion acting on the vascular supply of the organs through the nervous system.

OPHTHALMOLOGY.

Ophthalmia Neonatorum and Irachema.

Some useful statistics on the incidence of ophthalmia neonatorum have been published by WHARTON and SYDNEY STEPHENSON. The report of the Committee on Preventable Blindness appointed at the International Conference on the Blind in 1908 adds further weight to the cognate recommendations of the committee of the British Medical Association on Ophthalmia Neonatorum and of the committee of the American Medical Association previously issued. It may be confidently expected that some practical advantage will accrue from these authoritative statements and suggestions, and that the devastations of the disease, resulting so often in blindness, will be checked. Of more purely scientific interest are the cases of metastatic gonorrheal conjunctivitis published by McKEE and others.

Another contagious disease of the conjunctiva having widespread disastrous results is trachoma. No further steps to prevent its introduction and propagation in England by alien immigrants can be recorded, but some advance appears to have been made in determining its cause. The bodies originally described by PROWAZEK and HALBERSTÄDTER, working in Java, have been further Arguments are adduced for regarding them as the specific organism of the disease, but it would be premature to adopt this view, and until successful culture and inoculation experiments have been carried out it will be wise to withhold a definite opinion.

Cataraot.

Interest has centred during the past year in the campaign in favour of extraction of cataract in the capsule, led by the indomitable Major HENRY SMITH, I.M.S., of Jullundur in the Punjab. The failure of Major SMITH'S colleagues in other parts of India to confirm his brilliant results is now ancient history, but he is still undaunted and even has commenced to cast ridicule upon his opponents. A solid phalanx of his supporters, composed, it is true, chiefly of his own pupils, appeared at the Indian Medical Congress at Bombay. Perhaps the most important contribution to the discussion was the paper by Captain A. E. J. LISTER, I.M.S., on the after-effects of vitreous escape, which was published in a recent number of THE LANCET. From this it would appear that escape of vitreous may entail relatively little deleterious result. The extraordinary infrequency of the complication in the hands of Major SMITH and his supporters as compared with other operators of at least equal status still remains unexplained.

Glaucoma.

SCHREIBER and WENGLER have produced secondary glaucoma experimentally by the injection of electrolytically precipitated iron into the anterior chamber of rabbits. The plasticity of the coats of the eye in these animals led to the production of an artificial hydrophthalmia as the result of the blockage of the filtration angle. A further case of buphthalmia in association with neurofibromatosis has been reported by KOMOTO. The number of such cases now on record precludes the view that the association is fortuitous, but the etiological relationship is extremely obscure. The operative treatment of chronic glaucoma is so unsatisfactory that many surgeons are engaged in devising new operations or modifications of old methods with a view to obtaining more gratifying results. Cyclodialysis has not gathered many supporters in this country, and most attempts have been directed towards obtaining permanent filtration through the scar of the operation. HERBERT'S and LAGRANGE'S operations are still sub judice. DUFOUR advocates GAYET's methods by section of the eyeball from without inwards in certain cases of difficult iridectomy, a method also recommended by BROOKSBANK JAMES in a modified form with the object of providing filtration.

Optic Neuritis.

The significance of papillodema or choked disc in cases of intracranial disease is a subject of perennial discussion. More attention than usual has been attracted to it recently owing to the publication by PATON of classified records derived from the National Hospital for the Paralysed and Epileptic. It has undoubtedly been the general opinion of most clinicians that optic neuritis commences first and is usually most severe on the same side as the intracranial tumour. These records do not bear out this view, but in spite of the large number of valuable cases collected and collated, further and more exhaustive investigations must be undertaken before the localising value of the neuritis can be considered definitely disproved. The marvellous effect in relieving intracranial pressure by trephining upon the papillædema, the rapid subsidence of the swelling, and the restoration of vision have been the subject of papers by E. VON HIPPEL, DE SCHWEINITZ and HOLLOWAY, RISIEN RUSSELL, and others. The result is so striking that there is less room for difference of opinion on the efficacy of this palliative treatment, and its bearing upon the causation of the condition must be given preponderant weight in the investigated by GREEFF, MIJASCHITA, and many others. discussion of any theory of the pathogenesis of papilloedema.

The Effect of Light on the Eye.

Much attention has been devoted of late to the action of spectral rays upon various parts of the eye, and particularly to the relative part played by ultra-violet rays. Sun-burn, snow-blindness, and ophthalmia electrica have long been recognised as due to this agency. Less certain is their influence in producing erythropsia, and it is emphatically denied by BEST. Experimentally the effects of ultra-violet rays have been investigated by HESS, BIRCH-HIRSCHFELD, SCHANZ and STOCKHAUSEN, and others. The detrimental qualities of these rays have, perhaps, been over-estimated, and there is now a tendency to attribute more of the results to rays of the visible spectrum. At the same time there is ample evidence that excess of rays of short-wave length in ordinary illuminants is deleterious, and it is fortunate that ordinary glass globes form an effectual barrier to the passage of most of them.

During the year a society called the Illuminating Engineering Society has been started to study and discuss the physical and physiological problems of illumination. It consists of oil, gas, and electric light engineers, architects, physicists, physiologists, and so on—all, indeed, who are in any way interested in the subject. The opening meeting was held recently, when an address was delivered by the first President, Professor Silvanus Thompson.

Vaccines and Serum Diagnosis.

The uncertainty of the interpretation of the results and the occasionally disastrous effects of Calmette's conjunctival tuberculin reaction have led to its falling into general disrepute. It has given place to von Pirquet's skin reaction of allied nature, which is being vigorously investigated and may afford a valuable means of diagnosis. The opsonic index, too, has fallen somewhat in favour owing to the relatively enormous error of experiment which attends its application in most cases. It has not succeeded in establishing its value as a control of treatment, but the use of tuberculin as a therapeutic agent still retains its place. The rôle of autocytotoxins in the causation of intra-ocular disease offers a promising field of experimental investigation. The researches of ZUR NEDDEN on the production of retinal changes by nephrotoxins have led Golowin to claim priority for himself and his pupils. He has drawn attention to their work in such various fields as albuminuric retinitis, iridocyclitis, sympathetic ophthalmia, and so on.

Therapeutics.

The light treatment of tubercle of the conjunctiva is advocated by LUNDSGAARD of Copenhagen, who brings forward successful illustrative cases. The value of zinc ionisation in the treatment of rodent ulcer has been demonstrated, and the application of the method to diseases affecting the eyeball is being carried out by WIRTZ and The more superficial diseases, such as those involving the cornea and sclerotic, offer the most promising cases for this mode of treatment. Penetration of the therapeutic agent by ionisation is so superficial that little effect can be expected upon such diseases as irido-cyclitis, &c. Atoxyl, used widely in the treatment of trypanosomiasis and other diseases, is not without danger to the eyes. Clinical examples of optic atrophy due to it have been recorded by COPPEZ and others, and this condition has been produced experimentally. Bile salts have a deterrent effect upon the growth of gonococci in vitro; Löhlein finds that they may be used locally to the conjunctiva with advantage. The operative procedures for glaucoma have been discussed elsewhere. MULES'S operation has received some discussion, notably by WEBSTER Fox of Philadelphia. He advocates delayed implantation of a gold globe in cases where the eyeball has been previously removed, a modification of the operation introduced by ADAMS FROST. ELSCHNIG and his

pupil WALDSTEIN prefer to use spheres made of elder pith for such purposes, on the ground that the interstices between the fibres become filled with granulation tissue.

WHARTON has published statistics of 50 cases of extraction of particles of metal from the interior of the eye. The ring magnet, introduced by MELLINGER, to replace HAAB'S, VOLKMANN'S, and other giant magnets for the extraction of magnetisable foreign bodies, has been criticised by various surgeons. It has been adopted by PERCIVAL at Newcastleon-Tyne, who points out the disadvantage of the upright posture of the patient—a criticism which applies to the older form of HAAB'S magnet. SCHIRMER cites other disadvantages, and it is doubtful whether it will succeed in replacing its rivals.

Opportunity was afforded ophthalmic surgeons for seeing and handling new instruments for diagnosis and treatment at the London Ophthalmic Exhibition held in March. This purely trade exhibition serves a distinctly useful purpose, and its success will doubtless ensure its annual repetition.

Literature.

The past year has not been distinguished by the publication of any book of outstanding merit in ophthalmology. The German handbook by various authors, edited by Professor AXENFELD, though good in parts, is not likely to displace those already in the field. The exhaustive treatise issued as the second edition of the handbook-a strange misnomer!-by GRARFE and SAEMISCH is still far from completion after a spasmodic course extending over more than ten years. In point of time the French Encyclopædia. edited by Professors LAGRANGE and VALUDE, easily outstrips the rival German publication. Begun in 1903, it is rapidly approaching completion. It is not so exhaustive as the GRAEFE-SAEMISCH handbook, but both occupy useful places in ophthalmic literature; neither can be disregarded by ophthalmologists. As a work of reference the German treatise is much superior. Professors WILBRAND and SAENGER continue to issue volumes of their monumental "Neurology of the Eye," a work indispensable both to neurologists and ophthalmologists, but marred by a tendency to diffuseness and the inclusion of matter generally regarded as extraneous to the subject.

DENTAL SURGERY.

Perhaps the most interesting feature to record in the year just closing is the jubilee of the institution by the Royal College of Surgeons of England of the Diploma of Licentiate in Dental Surgery. To celebrate this event, the Council of the Royal College entertained at a dinner a large number of distinguished members of the dental profession on Dec. 2nd. The bond between the dental profession and the Royal College of Surgeons has been further strengthened by the transference to the latter body of the unique collection of specimens forming the museum of the Odontological Section of the Royal Society of Medicine.

The principal subjects which have attracted the attention of the dental profession during the past year are the administration of anæsthetics by dental practitioners and the question of State service of dentistry. The latter question was very ably dealt with in a paper by Mr. LAWSON DODD. In reviewing the question of the policy of the profession with regard to the work of preventive dentistry, he states that it is clear that the first aim should be the extension and multiplication of the facilities for the care of the teeth to the mass of the population, and especially to the elementary school children, and he favours, like others, the establishment of dental clinics. In Germany the authorities are already acting on these lines and in no less than 50 of

¹ British Dental Journal, June, 1909.

the cities and towns dental clinics have already been established with most excellent results. The Cambridge clinic, which was the first to be established in this country, has already accomplished most useful work.

The administration of anæsthetics by dental practitioners has been vigorously discussed during the year. The Bill promoted in the early part of this year, which strove to prevent any but fully qualified medical men from administering anæsthetics, was met by strenuous opposition on the part of dental surgeons, whose point of view has now been definitely accepted by the General Medical Council. It is interesting to note in connexion with this question that the Royal College of Surgeons of England have during the year decided that in future all candidates for the Licence in Dental Surgery shall undergo a course of instruction in the practical administration of anæsthetics used in

An International Dental Congress was held in Berlin in the month of August. Over 2000 people were present, and the Congress proved of great scientific value.

Unfortunately, the list of deaths to be recorded is a long one. In the early part of the year Mr. T. H. G. HARDING passed away. He was one of the first students to enter the Royal Dental Hospital, and for some years served on the staff of the hospital. The dental profession in Ireland has been robbed of one of its most distinguished members by the death of Dr. R. T. SLACK. Commencing his professional life as a physician, he was early overtaken by deafness. He subsequently studied dentistry, and with others formed the Dental Hospital in Dublin. We have also to record the death of Mr. BREWARD NEALE, a Past President of the British Dental Association, and of Mr. A. W. HARLAN of Chicago, well known to the dental profession in this country by his many contributions to current literature. He founded the Dental Review in 1887, and was secretarygeneral to the Second International Dental Congress of Chicago. The death of SAMUEL LEE RYMER has removed from our midst one of the few remaining practitioners who took part in the controversy in the early days between those who favoured a dental diploma being granted by the Royal College of Surgeons and those who were in favour of a separate college of dentists.

Papers.

One of the most valuable papers published during the year was that by Mr. ASHLEY DENSHAM, 2 entitled, "A Review of the Progress of Dental Science and Literature from the Earliest Ages." According to this author the earliest references to odontology are to be found in Egyptian times, and a large number of dental diseases are mentioned in the "Ebers Papyri." These records were commenced about 3700 B.C. and ended in 1550 B.C. In the paper is a résumé of the accounts given by HIPPOCRATES of dental and oral diseases, and the writer dwells very fully on the documentary evidence that dentistry was practised amongst the Romans. The paper, as we have remarked, is a most valuable contribution to the history of dentistry. Another paper 3 bearing on the rise and progress of dentistry was read by Mr. THEODORE SHENNEN. This author dealt with the operative side of dentistry and illustrated his remarks with pictures of instruments taken from various museums.

In an address before the International Dental Congress Mr. J. H. MUMMERY ' gave a very lucid account of Professor MILLER'S contributions to dental science, dwelling more especially upon his experimental investigations on caries and erosion of the teeth and also his investigations into the question of immunity from caries.

In a paper before the International Medical Congress in Budapest Mr. KENNETH W. GOADBY stated that with regard to the etiology of dental caries he has found that in mouths where dental caries is not present organisms capable of fermenting lactose are less frequently present than in those in which caries is present. In mouths where caries is present the lactose fermenters are invariably present, a point which he thinks must have a bearing on the etiology of

In a communication on the eruption of the teeth Mr. W. W. JAMES 5 drew attention to the intimate connexion, which exists between the developing tooth and the oral epithelium. The chief function of this band of epithelium, he considers, is to guide the tooth to its position in the gum, the path of eruption of the tooth being prepared by degeneration of the epithelium. The tissues, which are apparently very dense over the tooth, become loosened and rarefied by the ramifications of the epithelium, and partly by the changes in the zone of epithelium. Mr. JAMES inclines to the view that the growth of the teeth plays an important part in the process of eruption, but he does not consider that it is sufficient to account for the whole process.

Mr. HOPEWELL-SMITH, 6 under the title of "Some Leaves from a Pathological Notebook," gives an account of several cases of pathological interest. In one case of erosion which is very fully described he considers that the lesion was due to faulty metabolism of the gingival labial tissues. Under the title of "A Case of Infective Disease of the Jaws associated with the Absorption of the Teeth,"7 this author gives a detailed account of some curious pathological changes affecting the molar teeth of an adult.

Mr. H. P. PICKERILL 8 has given the results of his experimental investigation into the antiseptic value of filling materials and has shown that the two filling materials which possess the greatest antiseptic properties are copper amalgam and oxysulphate of zinc. Mr. H. SIMMS 9 has also reported his experimental investigations into the action of formalin and has shown that formalin is a most valuable asset in the treatment of septic conditions of the teeth. Many papers have appeared on translucent cements, and there is very little doubt that this material has proved a useful adjunct to the fillings already used. It is, however, open to considerable improvement.

The indifferent results which may follow the extraction of teeth in process of regulation have been referred to by Mr. A. C. LOCKETT. 10 His paper is well illustrated and is certainly worthy of the attention of those who incline to the view that extraction is the best remedy for crowded conditions of the teeth.

In the domain of prosthetic dentistry Mr. D. M SHAW 11 has drawn attention to the question of swaging by hammer and the press. This paper is a good example of the way in which dental questions are now being treated and discussed on scientific lines.

A case in which a misplaced lower third molar was situated in the ascending ramus of the mandible near the sigmoid notch was reported by Mr. J. J. Andrews. 12 Suppuration had occurred in the tooth sac, and it was only by means of radiography that its presence was noticed.

Literature.

Of the new books published during the year attention may be drawn to "An Atlas of Skiagrams Illustrating Development of the Teeth," by Professor J. SYMINGTON and Mr. J. C. RANKIN. This is the first effort made to deal with the question of development of the teeth by means of radiography. and the method adopted holds out every prospect of success. A work worthy of attention is "Anatomie de la Bouche et des Dents," by Dr. DIEULEFE and Dr. HERPIN. It is interest. ing to note that these authors describe the torus palatinus as the "torus palatinus sagittalis," and they describe two forms, the one long and narrow, and the other wide anteriorly and posteriorly. They consider that it is a growth of progressive nature and therefore disagree with the view held by some anatomists that it is a racial characteristic. A useful work on Operative Dentistry, by various authors, has been published in America under the editorship of C. N. JOHNSON. Other works worthy of notice are :- "Our Teeth, How Built Up, How Destroyed, How Preserved," Mr. R. D. PEDLEY and Mr. F. HARRISON; "Dental Surgery Notes," Mr. E. B. DOWSETT; "An Atlas of Dental Extraction," Mr. E. Wallis; and "The Principles and Practice of Operative Dentistry," by Mr. J. L. MARSHALL (third edition).

AN.ESTHETICS.

Legal Aspects of Anæsthesia.

The advisability of securing legislative enactment regulating the use of anæsthetics has been discussed at some length in the columns of THE LANCET and elsewhere. It was pointed out at meetings held by the Medico-Legal Society that the public at present are not protected from unqualified and ignorant persons who undertake the responsible duties of an anæsthetist. Deaths both from the use of general and local anæsthetics have occurred in such circumstances Several Anæsthetics Bills have been promoted which, while differing in detail, have all agreed in making it a penal offence for unqualified persons to give anæsthetics, except in cases of emergency. It has been also urged that every death under an ansisthetic shall be notified to a coroner, and medical men should be forbidden to certify the cause of death until an inquest has been held. The chief ground of controversy has been whether or not dentists having no medical qualification should be exempted from such penal clauses. The necessity for more efficient education in anæsthetics and making it compulsory that some instruction in anæsthetics should be given before granting a diploma to practise has been strongly urged. Meetings in the Section of Anæsthetics of the Royal Society of Medicine 1 and the Medical Society,2 reports of which have appeared in our columns, have been held, at which this subject has been considered. At these discussions the same lack of unanimity was revealed which has been shown in the letters bearing upon this question, which have appeared in the correspondence columns of THE LANCET and elsewhere. A Committee of the General Medical Council has reported to that body upon the proposed legislation, and the Council on Nov. 27th recommended that the conclusions appended should be transmitted to the Lord President of the Privy Council: (1) That the Council deal with the educational part of the matter by "recommendations" to the licensing bodies and deprecate further legal enactment; (2) that it is desirable that the use of anæsthetics be restricted to medically qualified persons, but that dentists be allowed to employ certain anæsthetics which are to be scheduled; and (3) that it is inexpedient to create a new penal offence by rendering it illegal to sign a death certificate when the patient dies

after the use of an anæsthetic. The Council proposes to leave the decision of what constitutes "adequate practical instruction" in the uses of anæsthetics to the licensing bodies. The whole matter remains for the present in a condition of uncertainty as to the ultimate fate of the proposed Anæsthetics Bills. It has been urged as a reason for forbidding signing of death certificates before inquests on persons dying when an anæsthetic has been given that all such deaths should be recorded and be accessible for scientific investigation. This is no doubt important, but, as the President of the General Medical Council has pointed out, notification of these deaths could be made compulsory as in the case of infectious diseases. Sir VICTOR HORSLEY 3 has advanced reasons in favour of dentists administering ansesthetics; and, further, the Royal College of Surgeons of England has enacted that in future all candidates applying for the L.D.S. qualification shall receive adequate instruction in the use of anæsthetics. To meet this res lution the Royal Dental Hospital of London has instituted ints school a chair for a lecturer on anæsthetics, and has appointed an expert anæsthetist to discharge its duties. This school, at the same time, has arranged for the practical training of its students in the use of nitrous oxide gas for dental operations. Germane to this subject is the question of the legal responsibility of medical men as regards the employment of anæsthetics. Mr. A. D. COWBURN, who is atonce a medical man and a barrister-at-law, has dealt with some aspects of the matter in a paper read before the-Medico-Legal Society.4 He points out that, except in casesof gross carelessness or inefficiency, to make medical menliable for legal pains and penalties upon their losing a patientunder an anæsthetic would damage humanity at large. Indeed, it may be said that the general trend of opinion is at present opposed to the promotion of any further legislation which would involve fresh legal embarrassments to medical men and force them unnecessarily into the notoriety of coroners' courts, where they may be subjected to ignorant and unfair treatment.

General Anæsthetics.

ZUR VERTH³ attempts to apply to the human subject the knowledge gained by Dr. ZEIGLER'S experiments on rabbits and the methods introduced in Professor von BIER'S clinic by Dr. KLAPP. If the circulation is limited by tight bandaging of the limbs the amount of anæsthetic required to produce surgical narcosis is lessened and its danger proportionately diminished. This argument is, however, open to discussion, as our present knowledge enables us to say that the tissues of the body are damaged not by the actual quantity of anæsthetic so much as by the height of its tension in the blood and the tissues and by the concomitant cutting off of oxygen.

Dr. CRILE compares nitrous oxide and oxygen in general surgery with ether, and extols its use as less injurious to the recuperative powers of the tissues. Mr. J. F. TREWBY discusses the causes of obstruction to respiration during the use of continuous "gas" anæsthesia. He points out that the oro-pharyngeal aperture is always obliterated before the naso-pharyngeal, and that even moderate cyanosis causes overdistension of the veins of the neck and of the tongue and may lead to serious consequences.

Chloroform.

Dr. PAUL M. CHAPMAN⁸ has recorded a further series of cases in which he has successfully used Dubois's chloroform inhaler, which limits the percentage to 2. His experience

confirms that of all others who have adopted dosimetric chloroform methods, and is that perfect and safe narcosis can only be attained when some regulating inhaler is employed. Dr. N. H. Alcock, who has introduced an inhaler which is stated to give accurate percentages of chloroform, discusses the whole question of dosimetry in a fair and useful manner, and comes to the conclusion that the percentage method is the best, although he transcends the 2 per cent. limit and advises 2.5 per cent. or even 3 per cent. being used during the induction of anæsthesia. Although the paper fails to give full credit to the early workers in the field of dosimetric chloroformisation, it is of especial value as confirming what was proved by SNOW, PAUL BERT, and the Special Chloroform Committee of the British Medical Association. The use of such percentages as 2.5 and 3 during the induction period is rightly said to be dangerous unless adopted at the end of the second degree of narcosis, and then only with the utmost caution. Dr. ALCOCK emphasises the importance of reckoning with the unknown necessities of the patient under the adverse conditions incident to the surgical operating theatre, and makes out a strong case in favour of the use of a rigid percentage administration, even when such conditions exist. Many of the phenomena to which he refers as being somewhat bewildering are in fact recognised by anæsthetists as fairly common and are now explicable by the exhaustive work of EMBLEY and MARTIN as being vagal effects, and as such fraught with the utmost danger unless the strength of the vapour inhaled is kept at or below 2 per cent. No reference to these experiments apparently falls within the scope of Dr. Alcock's paper.

Shook during Anæsthesia: Heart Massage.

The treatment, prophylactic as well as remedial, was the subject of a discussion opened by Dr. DUDLEY BUXTON 10 before the Section of Anæsthetics of the Royal Society of Medicine. He pointed out that shock arose through lowered blood pressure and he dealt with the causes of this. Chloroform in large doses or high percentages lowers blood pressure through its action on either the nerve centres or heart muscle. Loss of blood, the proceedings of surgery, and ultimately inadequate oxygen supply lead to the same result. Adequate but low percentages of chloroform with the constant use of oxygen and attention to posture and maintenance of body temperature had in his practice greatly lessened shock as an after-effect of chloroform inhalation during grave surgical operations. Although this method has not been successful in many of the reported cases its value has been proved. Dr. V. B. ORR¹¹ contributed a valuable paper epitomising our knowledge of the subject to the proceedings of the Royal Society of Medicine, Section of Anæsthetics. He further details a successful case, and a similar recovery due to heart massage is narrated by Dr. E. H. STARLING. In the discussion upon the subject emphasis was justly laid by DUDLEY BUXTON upon the importance of differentiating between the various causes of heart failure and the early adoption in suitable cases of heart massage. Lectures dealing with

Artificial Respiration

have appeared in our columns by Dr. ARTHUR KEITH. 12 Although mainly directed to the question of resuscitating the drowned, much of what is said is applicable to forced respiration required in failure of respiration under anæsthetics. The value of the Schäfer method is recognised, although Dr. KEITH does not regard it as free from danger in rough hands.

Peroral Intubation

by Kuhn's method 13 supplies a valuable addition to the

armamentarium of the anæsthetist. Cases arise which are difficult to tracheotomise without loss of time, and for these and others when the venous hæmorrhage, due to cyanosis, offers especial dangers peroral intubation is most useful. It is also a far less serious procedure quâ sequelæ than a hasty operation upon the larynx or trachea. The dangers of anæmia in connexion with chloroform are dealt with by Dr. R. T. SUTHERLAND in the Intercolonial Medical Journal " and in our columns. 15

Ether.

In the communications upon this anæsthetic which have appeared during the year fresh advocates for a dosage and drop method have come forward. Dr. Boldt 16 inveighs against the indiscriminate use of strychnine in connexion with its administration; Dr. M. F. GOLDBERGER 17 extols spraying ethyl chloride and ether upon gauze covered by towelling fixed in a wire mask; and an editorial article of great value 18 reviews our knowledge of the uses of the gas and ether sequence and advises morphine and atropine to be given before the anæsthetic to lessen the amount required and to minimise the secretion from the mouth and lungs. The work of Dr. J. J. A. VAN KAATHOVEN, of Miss ALICE MACGRAW, and of A. OTTE 19 deserves attention. Dr. B. WRIGHT's research on "ether pneumonia" at the Johns Hopkins Hospital and the conclusions of R. REYBURN and C. RITTER all point to the fact that the allegations against ether are in fact only true when excessive and undue quantities of the anæsthetic are inhaled.

Scopolamine and Morphine.

Sir J. HALLIDAY CROOM 20 has given his experience of this method of obtaining analgesia during labour, but concerning the whole matter further information will be found in the Obstetrical Section of this revue. JOSEL A. BERNUTI 21 gives details of 600 cases. E. ZADRO 22 publishes his experience of 770 cases in which these drugs were injected before a general anæsthetic was employed. By employing very small doses ZADRO considers the method can be rendered safer, and its use, he avers, minimises the dangers consecutive upon prolonged operations upon patients under general anæsthetics, since less is required and less stimulation of the secreting glands occurs.

Delayed Poisoning following Chloroform Inhalation.

Two important researches have been undertaken to elucidate the effects of inhaling large and repeated doses of chloroform. Dr. John Howland and Dr. A. N. RICHARDS have investigated the question of "The Metabolism and Pathology of Delayed Chloroform Poisoning."23 After reviewing the literature they give details of their own research, which is really one involving the use of considerable quantities of chloroform, and no adequate attempt was made to observe whether pathological changes follow the employment c: chloroform when given in such a manner that only enough is inhaled to induce and maintain anæsthesia. This in no way detracts from the great value of the work Dr. HOWLAND and Dr. RICHARDS have done, but invalidates any application ef their conclusions beyond the definite state of poisoning by chloroform. Their experiments supply a strong reason for restricting the quantity of chloroform given, but do no furnish proof that chloroform, as such, necessarily cause the serious toxic conditions which they describe.

conclude that death occurred by acid intoxication or by the accumulation of products (amino-acids) of cell digestion, nor solely as a result of the excessive amount of protein lost—i.e., of tissue disintegrated. As they point out, starvation will produce as great a loss of protein and yet not prove fatal. "We are driven," they say, "to the quite indefinite and unsatisfactory view that death is due to the presence of toxic substances of an unknown nature" due to abnormal metabolism or failure on the part of the organism to neutralise toxic substances normally formed. They describe in careful detail the pathological changes found in the hepatic, lobules, the heart, and muscular tissues. Dr. G. H. WHIPPLE and Dr. J. A. Sperry 21 communicate a similar research upon this subject, finding that the symptoms of overdosing with chloroform in dogs are quite similar to those observed in man. The pathological lesions described are corroborative of those given by Dr. HOWLAND and Dr. RICHARDS, who point out that the pathological lesions described are by no means constant. Although patients are constantly inhaling unmeasured and unstinted quantities of chloroform, yet a very small percentage show even the slightest symptom—albuminuria, bilious urine, and so on-pointing to chloroform poisoning. The same symptoms and pathological changes have been recorded also in cases when chloroform has not been inhaled, so that we are compelled to believe there must be many factors, as yet unrecognised, active in the pathogenesis of this metabolic perversion. Dr. M. S. PEMBREY and Dr. E. I. SPRIGGS,25 in a paper dealing with the relation of acidosis to the carbon dioxide of the blood in diabetic coma, throw a sidelight upon acidosis which occasionally exists among the symptoms grouped under the misleading title of delayed chloroform poisoning. We know that the normal carbondioxide excretion is affected in chloroform poisoning and that that toxemia commonly is associated with glycosuria, but how far these pathological similarities can be admitted as evidence of a causal nexus is at present uncertain. Three deaths associated with chloroform poisoning are recorded 26 by Dr. T. C. SOMERVILLE; they are of the usual type, but with the exception of the first patient the surgical procedure may have been a factor in the case. A further alleged instance of delayed poisoning after chloroform is reported in our columns by Dr. A. A. WEIR. 27 Vomiting was absent in this case. Recovery under a mixed treatment of alkalies and glucose ensued. A point about the case was that the boy had taken chloroform upon a previous occasion without detriment. An extremely interesting paper upon acid intoxication by Dr. T. G. MOORHEAD 25 points out that failure in the metabolism is not always due to carbohydrate starvation, the factor upon the importance of which von Noorden insisted, but may be due to toxins generated in the alimentary canal or to a poison of the primary bacterial disease existing in the case. The absence of oxygen, it would appear, must be present as an active cause of the fatty changes in the tissues. VON JAKSCH has classified the conditions in which acid intoxication appears as (1) febrile; (2) diabetes; (3) malignant growths; (4) starvation; (5) certain psychoses; (6) dietetic; and (7) post-anæsthetic. Under the last heading it is important to recognise the possible coincidence of starvation and undue deprivation of oxygen. A. SIPPEL 29 has examined the records of 40 articles recording cases of post-operative acidosis, and has found that in them the surgical procedures interfered with the normal progress of the systemic blood current. From this he is led

to believe that the interference with the blood-supply is instrumental in the formation of toxins, and they promote acidosis. It may be noted, he remarks, that ROSENFELD'S researches upon the glycogenic function of the liver indicate that interference with glycogenic production predisposes to imperfect fat metabolism. SIPPEL advises that in all cases the glycogenic capacity of the liver and the amount of urea produced should be examined antecedently to the inhalation, and that before the operation as well as afterwards carbohydrates should be freely given. Dr. T. S. GITHENS deals in a long article 30 with the literature of this subject. He points out the dangers of starvation before operation, and extols the free ingestion of glucose. It must be admitted that the condition called delayed chloroform poisoning has been shown by recent research to be due to many causes, often hard to dissociate; of these, anæsthetics may or may not be an active or at least a determining cause, but the symptoms so often are consequent upon other circumstances and arise without anæsthetics being used that the phrase is misleading and should not be employed.

The Status Lymphaticus and Anæsthetics.

Various causes have contributed to force this subject into great prominence. Several deaths have taken place under anæsthetics, the cause of which was stated to be lymphatism. A prosecution for manslaughter has been undertaken against hairdressers who had employed a substance, tetrachloride of carbon, once used as a general anæsthetic. The lady who was shampooed died, and the defence advanced the view that the fatality was due to status lymphaticus, their contention being supported by the findings at the necropsy and the evidence of an expert pathologist. This view is strongly urged by Mr. R. E. HUMPHRY,³¹ and he advances very cogent reasons. Dr. S. H. DAUKES 32 reports a case of sudden death due to the persistent thymus. The circumstances of the death might have sustained a charge of manslaughter in the absence of a necropsy. The importance of recording such cases is obvious, for had the woman been under an anæsthetic, poisoning or overdosage would probably have been accepted as the cause of death. Mr. W. H. RAW 33 describes a similar case. Dr. DONALD J. MUNRO³¹ discusses the pathology of lymphatism, and points out its clinical characters. He has met with 15 cases which he regards as having been more or less markedly subjects of lymphatism. With nitrous oxide he has found the slightly "lymphatic" patient takes unusually large quantities to become unconscious, but the anæsthesia is very prolonged and profound. We assume that Dr. MUNRO means longer than the extended induction and increased quantity of gas inhaled would account for. He believes some persons who fall into the category covered by the term lymphatism are not rendered anæsthetic by even enormous quantities of nitrous oxide. Mixtures containing chloroform may cause dangerous symptoms, and chloroform is most likely to induce serious sequelæ. Dr. MUNRO'S experience is not in accord with some other observers who have stated that small quantities of general anæsthetics cause unconsciousness in the lymphatic state. He regards ether as less dangerous than chloroform, but admits that HENSLEY has recorded an ether fatality in status lymphaticus; however, severe hæmorrhage appears to have complicated this case. That the anæsthetic is not always fatal is exemplified by the evidence at an inquest upon a child who ultimately died under chloroform in a London hospital.35 This child was said to have undergone ten previous operations under an anæsthetic without mishap.

Mr. R. E. HUMPHRY 30 has published important communications dealing with status lymphaticus and believes he has met with several undoubted examples of this serious condition. He submits the following symptoms and physical signs as most important in forming a diagnosis in these difficult cases: 1. The existence of a persistent thymus is evidenced by a lowering of the upper border of the superficial cardiac dulness with or without fulness in the episternal notch. As he has pointed out, dulness to percussion over the manubrium is often absent, and if present may be due to other causes than hyperplasia of the thymus. 2. Uniform prominence of the lingual papillæ, especially the circumvallate and the nodules between them and the epiglottis. 3. Symmetrical enlargement of the thyroid. 4. Distant and muffled heart sounds and absence of the defined click usually heard as the valves close; a soft, weak, ill-sustained pulse. 5. Hyperplasia of the faucial, lingual, and pharyngeal tonsils associated with the presence of post-nasal vegetations. The enlargement of the liver and spleen, although confirmatory, is not to be relied upon. Dilatation of the pupils is sometimes present. A further discussion of the subject took place in the Section of Ansesthetics of the Royal Society of Medicine consecutive to the report of a death made by Mr. H. B. GARDNER. 37 There seems little doubt that deaths due to lymphatism while associated with the inhalation of an anæsthetic may be wrongly attributed directly to drug toxemia. Mr. HUMPHRY has pointed out that such fatalities frequently occur during light anæsthesia, either at the commencement of inhalation or at its close, when sutures are being inserted, and are possibly due to excitement, fear, or slight perception of pain, or even to the supervention of womiting. Whether such persons really run a greater risk than others who are poorly developed and suffer from an ill-nourished nervous system and poor circulation seems open to doubt. This was pointed out in the discussion and the practical deduction was made that such persons were more readily overdosed than the normal patient and more intolerant of asphyxial complications. Mr. R. W. S. WALKER records a further case (THE LANCET, Dec. 18th, p. 1816) of sudden death due to status lymphaticus. Operation was postponed on account of the infant's condition, and in the interval the death occurred.

Spinal Analgesia.

It would appear to be impossible at present to arrive at any clear view concerning the safety of this method. Opinions as discordant as they are obviously honest continue to flood the columns of medical literature. It is deplorable that while the whole subject is in a welter of confusion the lay press should be furnished with utterly inaccurate pronouncements about "new anæsthetics" and "perfectly safe procedures" as well as illustrations purporting to depict surgeons performing operations upon patients who have been stovainised and whose faces, we are reminded, are wreathed with smiles. The banality of all this is evident to the medical profession, but the public takes such matters quite seriously and believes the statements without reservation. At a meeting of the Medical Section of the Royal Society of Medicine Professor Jonnesco of Bucharest delivered an address explanatory of his method of securing spinal analgesia. He claimed to be able to produce analgesia from the crown of the head to the soles of the feet. The dangers of high injections are those arising from bulbar paralysis, and this the speaker asserts can be completely removed by simultaneous injection of small

doses of strychnine together with stovaine. His method >> has been described before the German Society of Surgery (Berlin) and the International Society of Surgery (Brussels), in THE LANCET, and at full length in the Clinical Journal by Mr. CANNY RYALL, and more recently by himself in the British Medical Journal. The solutions are prepared at the time of injection and stovaine is preferred, although novocaine also finds favour with M. JONNESCO. dose is varied according to the site of puncturei.e., the high puncture between the first and second dorsal spines, the low puncture between the last dorsal and first lumbar vertebræ. The exact amount of analgesic is determined by the age. The sitting position is adopted for the puncture, followed by the dorsal decubitus, with the head more or less depressed according to the height it is desired to carry the analgesia. M. JONNESCO thinks pricking the cord is harmless; he avers that his method has no contra-indications, and goes so far as to say that general spinal anæsthesia is absolutely safe. He speaks from an experience of 412 cases in which he has employed his new method, although he and his assistants have used spinal injections for a little over a thousand patients. The assertion that the intrathecal injection of minute quantities of strychnine will obviate poisoning of the medullary centres is startling when we recall the most recent study of the pharmacology of strychnine. We recently described a demonstration given by M. JONNESCO at the Seamen's Hospital.39 Three patients were injected, aged 32, 62, and 14. One case was held to be quite successful, and cervical glands were removed, one was partially successful, and one needed chloroform for the performance of the operation. Failure must not be accepted as a proof that the method is valueless, but it may be submitted that it must be considered as a warning against excessive zeal. The number of deaths following the low puncture prove that M. JONNESCO'S statement of the harmlessness of any intrathecal method is not fully justified by the known facts. Mr. McGavin 10 publishes, with Mr. G. Williams, a report on 250 cases in which stovaine-glucose solution was employed. The paper is a model of scientific caution, and although the results given are extremely good the authors are careful to avoid exaggeration and undue generalisation. One death occurred from uramia, and one from heart failure, in which case two injections were made, but these fatalities were considered not to be due to stovaine. Failures numbered 6 per cent., and various complications are recorded, such as sickness, headache, air-hunger, relaxation of the sphincter ani, with some pyrexia. Distinct motor paralysis occurred, as is usual, although M. JONNESCO was understood to affirm that in his high injections sensory rather than motor nerves were affected. It is not a little significant that at both the Surgical Congresses at Paris and Berlin those surgeons who have enjoyed the widest experience did not hesitate to speak of intrathecal injections as fraught with the gravest dangers. both because they so frequently led to the most tragic aftereffects, such as persistent paraplegia, bladder and rectal troubles, and because the death-rate was higher than that involved in the use of general anæsthesia. Thus BRAUN contends that the method exceeds general narcosis in danger. VON BIER, who has reported two deaths, advises the supersession of intrathecal injection by local analgesia, or by intravenous injections by a method noticed below. He also recommends, where it can be suitably employed, that it be associated with the preliminary use of scopolamine and morphine in order to obviate the subjective distress fel;

by the patient. BORCHARDT reports a death, and HOLLÄNDER mentions a case of a healthy subject in whose bony spine the injecting needle was broken, necessitating the performance of a laminectomy in order to remove the impacted fragment. TUFFIER, one of the most enthusiastic advocates of the method, has announced that he has wholly relinquished its use in abdominal sections, and now restricts it to low pelvic operations. HARTMANN, DELBET, and BEURNIER have recorded five deaths, while NÉLATON, GUINARD, REYNIER, and LE DENTU have given a formidable list of accidents and most serious sequelæ. To such evidence it is difficult to reconcile M. JONNESCO'S statement that the method is "absolutely safe." More than one death before operation have been recorded in the press in England alone during the year, so that the wiser and saner course seems to be, while admitting the extreme value of this procedure in suitable cases, to acknowledge its limitations and undoubted dangers. the discussion upon this subject at the annual general meeting of the British Medical Association held this year in Belfast Mr. J. CHIENE reported some successful cases and eulogised the merits of the method, while Mr. A. E. BARKER and Dr. Dudley Buxton pointed out the necessity for caution and less flamboyant praise. Admitting its utility, it was urged that the most experienced had met with a high death-rate and with sequelæ far more serious than had occurred when general anæsthetics were employed. Dr. J. W. STRUTHERS 12 furnishes a useful résumé of the subject and emphasises the fact that most of the advocates, while extolling spinal analgesia because its use is declared to abrogate shock by blocking the conveyance of nerve stimuli up the cord, yet have recorded a considerable number of cases in which collapse has occurred, and others in which more or less heart failure was present.

There is far from unanimity as to which drug is best if cocaine, admittedly most dangerous, is excluded. Dr. C. N. LE Brocq 43 has investigated the pharmacology of this subject and has arrived at the following conclusions. Arranged in order of their toxicity in frogs the analgesics are: alypin, cocaine, stovaine, nirvanine, β -eucaine lactate, tropacocaine, novocaine. They kill by paralysing the respiratory centre. Mammals are affected slightly differently, so that taking cocaine as unit of toxicity, these bo dies stand as follows: alypin, 1.25; nirvanine, 0.714; stovaine, 0.625; tropacocaine, 0.5; novocaine, 0.49; B-eucaine lactate, 0.414. However, some of these drugs are more irritating than others, stovaine, β -eucaine lactate, and tropacocaine being more so than cocaine, novocaine is less irritating, and so, although more toxic than some others, its non-irritating properties place it above them in value. It should be remarked that the toxicity of alypin is denied by some experimenters. P. HARDRUIN met with one death due to bulbar intoxication in 10 cases; K. Borszeky in 300 cases, with 8.7 per cent. failures, 1.3 per cent. incomplete analgesia, and several cases of serious collapse, so serious that he condemns the use of the method outside hospitals. OELSNER in 575 cases had 54 failures, one death possibly due to the anæsthetic, and six cases of serious collapse. BIRNBAUM reports a case of death due to the method, which took place nine days after the injection, and CIMAGLIA and LINDERSTERN mention some most grave sequelæ. Captain J.W. HOUGHTON,44 R.A.M.C., reports 34 successful cases of spinal analgesia practised in Sierra Leone. He used tropacocaine, omitting glucose, as a 5 per cent. solution has a specific gravity of 1.0106 and cerebro-spinal fluid has a specific gravity of 1.007. In two cases the operation had to be completed under chloroform as they were very prolonged, and so exceeded the

time during which the analgesia persisted. He institutes a comparison between tropacocaine and stovaine. Professor HOLLÄNDER in an article in the Deutsche Medizinische Wochensohrift 45 discusses the disadvantages and merits of the the method and reference is made to the maintenance of the tonicity of the intestinal muscle said to be lost after chloroform narcosis. It may be remarked that SHERRINGTON has shown that intestinal muscle is never paralysed by chloroform used in therapeutic doses. In their enthusiasm for new methods many of the advocates appear to overlook the accepted facts in the pharmacology of general anæsthetics. W. THOMASCHEWSKI 46 furnishes particulars of the results obtained in the Military Medical Academy at St. Petersburg: 104 cases—5 per cent. failures, 5 per cent. imperfect analgesia; no serious complications are mentioned, some collapse in one case, and headache with retching occasionally followed, and 60 per cent. showed transient albuminuria. Tropacocaine was employed, the dose varying between 0.05 and 0.09 gramme, and the operations were only on the pelvis and below. The cases were carefully selected. AVRAMESCO of Bucharest 47 points out that the aim of rachistovainisation is to anæsthetise the roots of the nerves and not the cord, and he describes the necessary technique. Mr. H. TYRRELL GRAY has described 48 his experience in 200 cases of spinal analgesia at Great Ormond-street Hospital for Children. He speaks in warm praise of the method for children, urging that its adoption has made surgical results more favourable. The paper supplies valuable information. The writer appears to accept a less gloomy view of the dangers of spinal injection in the case of children than is usually held. No death due entirely to stovaine occurred in the series here recorded. There is, however, a report 49 of an inquest on a fatality at this hospital which occurred under spinal analgesia. The infant was 16 months old and stovaine admittedly produced respiratory failure. An instructive table of the complications and sequelæ is furnished in Mr. GRAY's paper in our columns. Although he is greatly in favour of the procedure, he has taken obvious pains to present all aspects of the method he has employed and has succeeded in presenting a strong case to support his contentions. The actual number of cases is too small to establish the safety of the method, which at present seems to have a terribly high mortality. As was hinted at the discussion upon the subject at Belfast, to institute any useful comparison between the safety of spinal analgesic methods and that of general anæsthesia we must be careful to select as efficient exponents of chloroform anæsthesia as are those who adopt the intrathecal injection method.

Intravenous Injection: Local Analgesia.

Professor BIER'S 50 recognition of the dangers of spinal analgesia has led him to supplement local analgesia by a method of intravenous injection with inclusion of the analgesic within a circumscribed area by means of constricting bands. The limb is exsanguined by Esmarch's tourniquet, two rubber bandages are placed one on each side of the site of operation, a superficial vein is opened under local analgesia, and the analgesic selected is slowly injected into the vein. Novocaine with adrenalin is employed, and in the case of nervous persons its use is preceded by the injection of scopolamine and morphine. Dr. J. M. HILZROT 51 has tried this method with success and regards it as superior to the usual infiltration analgesia. Dr. C. M. PAGE and Dr. S. G. MACDONALD 52 describe the technique and cite nine

cases of its successful employment. W. A. V. OPPEL 53 has performed experiments to ascertain the toxicity of cocaine when injected into the arterial circulation, and concludes that the danger varies inversely to the width of the capillary bed. Thus the lethal dose in the aorta is twice that of the femoral artery, and eight to ten times that of the superior vena cava. Without giving definite indications for the use of the method, he considers it may have some, although a narrow field of, utility. C. RITTER'S 54 experiments upon the production of anæsthesia by intravenous injections, although not as yet of practical application to the surgery of man, are of interest. 10 cubic centimetres of a 1 per cent. cocaine solution injected into a superficial vein of a dog produces complete analgesia with muscular relaxation persisting for from 15 to 30 minutes.

Professor BRAUN 55 gives an important article on the use of local anæsthetics in hospital practice. In the service of R. H. ZWICKEN, of 1529 operations 398 were done under local analgesia, novocaine and suprarenin being employed.

When we say that this outline of the work which has been recorded during the year concerning local analgesia is necessarily not perfect, it will be gathered that the subject has been reinstated into a position of primary importance.

PUBLIC HEALTH.

There is the semblance of a paradox surrounding the statement that the greatest progress in the public health world during 1909 has been made outside its immediate limits, but the position can be expressed in another and less paradoxical fashion by saying that during the past year the confines of public health have been in actual practice so much extended that the extensions threaten for the moment to absorb and dominate the whole. It is as if a borough, say, with a population of 100,000 had so extended its limits as to comprise a total population of a quarter of a million, or as if the flood-gates of a river had been opened so wide that the precise contour of the main stream below had for a time been rendered difficult of determination. responsibilities and duties of medical officers of health have undergone great extension with successive legislative enactments, the fact still remains that a large proportion of the annual reports of the average medical officers of health is taken up with considerations as regards certain of the infectious diseases, whereas but a small section is devoted to the general well-being of the population. And thus, regarding the Report of the Royal Commission on Poor-law as being concerned with future developments only, it comes about that by far the more important public health event of the year 1909 has been

The Medical Inspection of School Children.

From the several more or less illustrative annual reports of school medical officers which we have from time to time noticed in our columns it will have been seen what an excellent start has been made owing to the tactful attitude of the Board of Education and the law-abiding character of the English people. In some instances the beginning has been but small and delayed, but, generally speaking, the local education authorities have thrown themselves into the work with a zeal which is of happy augury for future developments. No very hard and fast routine practice has been adopted as regards the appointment of the officers who carry out medical inspection. In some cases the work is being actually performed by medical officers of health, in others the medical officer of health acts as the supervising official, while the actual work of inspection is performed by specially

35 Beitrage zur Klinischen Chirurgie, Band lxii., Heft 3.

appointed medical officers or by the district medical officers of health. In other cases, again, the medical officers of health have been entirely excluded from both the supervisory and inspectorial duties. The most satisfactory method is probably that by means of which the medical officer of health acts as the supervising authority, as it is by this means that there is most likely to be proper coordination and cooperation between the health authorities. But in some cases where a whole-time medical officer of health can be obtained by fusing together several appointments there is obvious advantage in having the actual inspectorial work carried out by the medical officer of health. In fact, the medical inspection of school children can be made use of for increasing the number of whole-time medical officers of health. Several valuable memoranda have been issued by the Board of Education during 1909, and amongst them may be specifically mentioned an outline scheme for teaching hygiene and temperance to the scholars attending public elementary schools, and a joint memorandum by the medical officers of the Local Government Board and Board of Education upon administrative measures, which we noticed in our columns on Nov. 22nd.

The Problem of the Medical Treatment of School Children.

When the medical inspection of school children was begun the question of the treatment of the affected children, especially in rural districts, seemed an almost insoluble one. But experience is fortunately tending to show that after all the problem may not prove very difficult if full advantage be taken of existing institutions and if the principle of coördinating all the possible channels of assistance be properly held in view.

Although the bulk of the children in whom some defect is discovered are not at present treated, the defects are being dealt with in a fashion which goes far to warrant the conclusion that in the not very distant future the majority of the cases will obtain treatment in some fashion or another. Already general practitioners are accounting for a considerable number of the cases, while the hospitals of provincial towns are being found not unwilling to deal with cases occurring in the neighbourhood of the towns. In London the London County Council is receiving more assistance from the hospitals than was at one time anticipated. In certain instances school clinics are being provided, and the now very general provision of a school nurse is enabling pressure from time to time to be put upon neglectful parents and minor ailments to be dealt with. In certain districts glasses are being arranged for at a cheap rate, and it is found that under these conditions the parents are less slow to provide them for their children than when the usual rates obtain.

We may here recall the fact, which we announced in our issue of Dec. 4th, that as the result of correspondence between the Havant board of guardians and the Local Government Board the guardians have fixed a fee of £2 for the operative treatment of enlarged tonsils and adenoids by the district medical officer in the Havant union.

The Reports of the Poor-law Commission.

In its potential aspects, this report, looking now on the two as one, must be regarded as of first-class importance from a public health point of view, seeing that one of its incidental objects is to facilitate the early treatment of disease, and thus to prevent, so far as practicable, the prolonged and often fatal illnesses which result from neglect of medical advice. We have already dealt with this classical report and its various appendices in a series of special articles, and for a summary of the Commission's conclusions reference may be made thereto. But it may be pointed out that even if only a portion of the recommendations be acted upon the indirect health effects must be enormous. The prevention of the effects of poverty by

Munchener Medicinische Wochenschrift, No. 35, August 31st.
Berliner Klinische Wochenschrift, Sept. 13th.

insuring against unemployment and by the establishment of labour bureaus and other agencies would in itself be a public health step of the first magnitude; and if there be also brought about the cooperation and coordination of the numerous agencies already engaged in philanthropic work far greater use will be made of all existing institutions than is at present the case. It is, however, of supreme importance that in any legislation or administration procedures based upon the Commission's report the purely philanthropic element shall not bulk too largely. It is easy by the reckless distribution of outdoor relief to create poverty, dependence, and parasitism, as well as to lower the wages of those who are endeavouring to maintain themselves without recourse to the rates; and similarly, the workhouses may be made so attractive that the inducements to return to work may be wanting. But this danger has been appreciated by the Commissioners and to some extent guarded against. In so far as the medical profession is concerned there is much in the report to be grateful for, and tributes of praise have been paid to the self-denying work of district medical officers throughout the country. Still, it is clear on all hands that there is much room for improvement in the existing condition of affairs and the proposal that domiciliary medical assistance is to be conditional upon the maintenance of a healthy dwelling and good habits should, if rigidly enforced, lead to very great improvement in the homes of the poorer classes. And, finally, the fact that the Commission has realised and advised that the Poor-law medical officers of the Local Government Board should be increased in number so as to provide for the periodic inspection of both indoor and outdoor relief arrangements shows that in the future the services of medical men will be much more ntilised than heretofore. The Commissioners have evidently looked with rather wistful eyes at the vast organisation which has existed in Germany for so many years whereby there is compulsory insurance against sickness, invalidity, and old age, but they found the subject too vast to study in detail. This is, we think, a regrettable feature of the report, since the proposed extension of the compulsory system in Germany is in itself proof of the vast success of the measure, and could it have been adopted in this country with modifications little fear would have remained of the danger of the growth of parasitism which is clearly recognised both in the Majority and Minority Reports.

The Control of Imported Foods.

The enormous importance of protecting the 45,000,000 of our population from the introduction of unwholesome food can only be properly understood when it is appreciated that the bulk of our meat-supply alone is received from abroad. Important as is the control of much of our home produce, it is absolutely essential, if we are to be protected from more or less wholesale misrepresentation, that the greatest circumspection should be exercised as regards all our food imports, seeing that many of them reach our shores in such a condition that the determination of their unwholesomeness is an exceedingly difficult matter. Thanks, however, to the powers conferred by the Public Health (Regulations as to Foods) Act, 1907, the Local Government Board has by means of the several valuable Orders which have been issued developed a system of inspection of imported foods which must ultimately render our control of such foods very thorough. These Orders have placed a considerable burden upon the sanitary staffs of our principal seaports, where special inspectors have been appointed to act under the direction of the medical officers of health and to carry out the wide powers which the regulations have conferred upon port sanitary authorities. The important services which these authorities are thus rendering, not only to their own districts, but also to the whole country, deserve | and if the open-air treatment of infectious disease proves a

recognition. Unsound meat and canned goods, and a large variety of other articles have been discovered and refused admission or destroyed; the importation of meat foods treated with preservatives and meat in the form of scraps has been checked, while the regulations have enabled foods which, for one reason or another, require special examination-e.g., pork from China-to be passed only after careful and detailed inspection. It is a tribute to the care with which the regulations have been drafted, and also to the tactful work of the health officers concerned, that food importers themselves are more often the first to recognise their value and to assist the sanitary authorities in their administration. While our present laws governing the inspection of meats, milk, and food generally leave much to be desired, sanitary authorities are evidently finding it practicable to increase their efficiency in these matters under existing powers; and reports from various districts testify to the greater attention which is being devoted to these questions as well as to those relating to adulteration of food and the Sale of Food and Drugs Acts. The Local Government Board has materially contributed to this result during the year by the inquiries of its inspectors of foods, whose reports have contained the results of valuable investigations into the wholesomeness of canned meats, the use of preservatives in cream, the fumigation of foods with formaldehyde, and similar matters. It cannot, however, be said that in respect of rural districts and the smaller urban districts there is, as regards home-grown meat and other foods, such adequate control as could be wished for, and the annual reports of medical officers of health of such districts might profitably contain more information upon this important subject. The disposal of the carcasses of animals which have died a natural death is always a mysterious matter, and more vigilance in this connexion, as also in the visitation of slaughter-houses, is urgently called for. It is regrettable that the agitation or a purer milk-supply has not resulted in the passage of a satisfactory Milk Bill through Parliament, but we must hope that the next report of the Royal Commission on Tuberculosis will galvanise public health authorities to renewed activity.

Isolation Hospitals.

In certain hospitals, and notably in the case of Nottingham, the experiment is being tried of treating cases of infectious disease by the open-air method, and hospital administrators are awaiting the results of experiments upon a sufficiently large scale with great interest. Notwithstanding the attacks made on isolation hospitals within recent years there are no good grounds for believing that the demand on the part of the public for the continued provision of these. institutions, at any rate in urban districts, is likely to undergo material reduction, although there are indications that the rôle of the isolation hospital may in future need some modification.

Investigations into the behaviour of infectious disease in other countries and comparison between different towns at home have compelled epidemiologists to recognise the fact that isolation hospitals do not hold the position as controllers of infectious disease which was at one attributed to them. In addition, the study of epidemics has taught us that infectious disease spreads largely through the media of unrecognised cases, and that consequently it is difficult, if not impracticable, to entirely circumvent infection by dealing with recognised cases alone. But, nevertheless, the isolation hospital has a very definite position in the administrative machinery of public health, and the time is approaching when there will be very few localities without some provision of this kind. Unfortunately, the cost per bed in the case of some of the more elaborate institutions has been so great as to act as a deterrent to small local authorities,

success it may perhaps be possible very materially to reduce the cost of these establishments.

Tuberculosis.

The Royal Commission which is considering the relation of human to bovine tuberculosis is still sitting, and until it finally closes its books and presents its last report we must remain in ignorance as to the amount of human tuberculosis which is to be regarded as being probably of bovine origin. But in the meantime the investigations which are being made in connexion with the milk supplied to our large towns are showing what a very large percentage of such milk contains the tubercle bacillus, and as a consequence how frequently tubercle bacilli of bovine origin are being introduced into the intestinal tract of children as well as of adults. To a certain extent it is to be feared that the absence of a final pronouncement by the Royal Commission referred to is leading to all our efforts being directed solely against the tubercle bacillus contained in the sputum of recognised cases of "open" tuberculosis, and the question which remains for discussion is whether some disappointment may not be realised when critical epidemiologists and statisticians unite in investigation as to the results which have followed efforts made solely on these lines. Already we find critical persons asking whether the escape of the unrecognised cases of tuberculosis may not render it as difficult to demonstrate in the future the result of certain administrative methods in connexion with tuberculosis as it has been to show statistically the effect upon the prevalence of scarlet fever of the operations of notification, disinfection, and isolation. But it is impossible to doubt the value of the work which has for so many years been carried out in certain of our large towns in connexion with tuberculosis.

At the same time a very great deal depends upon how far the administrative machinery which is being devised is utilised towards encouraging persons affected or threatened with pulmonary tuberculosis to seek medical advice at the earliest practicable moment; and encouragement or the reverse in this sense is mixed up in very intimate and dominant fashion with the use or abuse which is made of the knowledge obtained through notification, whether of a voluntary or compulsory character matters little. If such knowledge has the effect of leading to the workers losing their employment or to their finding it difficult to procure fresh employment when they are discharged from sanatoriums administrative measures may defeat their own ends by leading to delay in seeking medical advice as well as to the suppression of the truth in directions which will at once occur to anyone familiar with the difficulties of obtaining a livelihood. This danger has been foreseen and, so far as practicable, discounted by the eminently moderate memorandum of the medical officer of the Local Government Board of England and Wales,1 which, under the heading, "Procedure in Official Investigations," points out that, "above all, the investigators must not pursue inquiries in a manner or give information that may prevent a consumptive patient from continuing to earn his livelihood." It is this sentence which is largely the key to the whole administrative position. The compulsory notification of pauper cases of pulmonary tuberculosis has been in operation during 1909, but it is not until the annual reports of medical officers of health for the past year reach us that any idea of the results can be formed. The experience gained by a few years of this practice should prove of considerable value. Compulsory notification of this disease has also been introduced for a limited period into the city of Glasgow, and the experience of this large population will subsequently be available to compare with that of Sheffield and Bolton.

Useful work has been carried out during the year through

the medium of the Tuberculosis Exhibition of the National Association for the Prevention of Tuberculosis and the conferences held in different parts in connexion with such exhibition.

Sanatoriums for Pulmonary Tuberculosis.

Encouraging progress in the provision of additional accommodation for early cases of pulmonary tuberculosis has been made during 1909, although, so far as we are aware, no local authority has as yet followed the example set by the city of Birmingham and provided an institution on its own account. But other local authorities are watching the Birmingham experiment closely, and when adequate experience as regards the after-results has been acquired they will consider whether the saving of life justifies expenditure in this direction or whether the money may be more usefully spent in improving housing conditions or possibly in the establishment of an antituberculosis dispensary. In the meantime, other local authorities are making experiments on a less ambitious scale by contributing to the funds of existing sanatoriums so as to have a certain number of beds at their disposal, and a similar observation applies to a small number of boards of guardians.

Additions have been made during 1909 to the number of beds at several sanatoriums. The Society for the Prevention and Cure of Consumption in the county of Durham has opened a sanatorium for women at Wolsingham, thus placing to its credit two valuable institutions, the sanatorium for men at Stanhope having for several years done excellent work and to a large extent solved the problem of the provision of a self-supporting sanatorium for the working classes. On the other side of the North of England the Westmorland sanatorium has extended its accommodation so as to provide 52 beds, and, largely through the munificence of Dr. W. S. PAGET-TOMLINSON, who has already done so much for the sanatorium, a home for advanced cases of this disease is, we believe, being provided at a cost of about £5000. This home is to afford accommodation for 20 patients. In the eastern counties a further extension of the children's sanatorium at Holt in Norfolk is, it seems, about to be undertaken. Most of the existing sanatoriums still complain in their annual reports that the cases which they receive are already too advanced when they are admitted, and this same complaint comes both from sanatoriums in connexion with which medical referees are appointed as well as from those There is now a growing possessing no such officers. tendency for the medical superintendents themselves to examine the applicants for admission before they are sent to the sanatorium, a precaution which has, we learn, been adopted in connexion with applicants for admission to King Edward VII. Sanatorium at Midhurst. With the advent of early and suitable cases greater scope is afforded for the exercise of graduated labour amongst the patients. and a great deal of work in this sense is now being undertaken at numerous sanatoriums, the work in some cases being of a nature to fit the patient to obtain other means of livelihood on discharge.

The results of sanatorium treatment cannot, we fear, be accurately assessed until the statistics are presented in such a fashion as to enable the cases of each year to be followed separately throughout succeeding years, and this practice is as yet by no means uniformly adopted. But in the case of the Kelling and the Durham sanatoriums, as well as in certain others, the cases are thus set out, and it is clear that with really early and suitable cases the chances of restoration to work for many years are very great. Critics of these favourable results are wont to suggest that these are the cases which would have recovered in any circumstances; indeed, they would say that in olden times these are the very cases

which would have passed unrecognised until, perchance, the post-mortem table was reached. But although there is theoretically some force in this criticism, we do not think that workers in sanatoriums will be likely to regard it as fairly meeting the facts.

The Housing and Town Planning Act.

We have so recently dealt with this measure in its passage through both Houses of Parliament that orief reference need only now be made to it. The powers which it confers upon the Local Government Board, county councils, and other local authorities are very great, and with these powers wisely administered there should be brought about great improvement in the conditions under which many of the poor are now living, and gradually there should rise up in the environments of existing towns aggregations of houses so arranged as to afford to the occupiers all the essentials of healthy and cheerful living. This enactment will also in effect materially augment the usefulness of county medical officers, who will now have their duties defined for them and possess a sense of security of office. We wonder how long it will be necessary to wait until the same protection is afforded to the district medical officers of health, who, as a matter of fact, need it more than the county officers.

Enterio Fever "Carriers,"

A considerable amount of research work has been carried out in this country during 1909 in connexion with the extremely interesting problem of the so-called "chronic" and "temporary" enteric fever carriers, and two memoranda upon the subject have been issued by the Director-General of the Army Medical Department.2 But we are still very far from knowing the importance of these "carriers" in the causation of either epidemic or endemic enteric fever. The Germans are inclined to attribute a very extensive rôle to these "carriers." and in this country it is clear that occasionally enteric fever convalescents have been responsible for several cases at irregular intervals. It would not seem a very difficult matter to determine what has been the behaviour of enteric fever in towns such as Maidstone, Newport (Isle of Wight), and Worthing since the occurrence of the outbreak of that disease at these places, as presumably the names of all those attacked, as well as the locality of the houses which they have subsequently occupied, could be easily ascertained. Perhaps the medical officers of health of these towns can be induced to investigate the matter. But these "carrier" cases raise some extremely important epidemiological problems apart from the question of the precise amount of enteric fever for which they may be held responsible. It is clear from much of the work done relative to "temporary" carriers that the enteric fever bacilli may be present in large numbers in persons who show no sign of this disease, and this consideration would seem to raise some question as to the pathogenicity of the bacillus itself, and, as Dr. J. C. G. LEDINGHAM has observed, "It may be that we are at the parting of the ways in our conception of The recent finding of the typhoid bacillus in the blood of cases which proved on post-mortem examination to be cases of tuberculosis (BUSSE and others) is perhaps apt to shake our notion of the typhoid bacillus as the causative agent of enteric fever." Events such as these must, as it were, make us pause before we draw inferences as to the influence of these carrier cases, more especially when we are told that perhaps some 3 to 4 per cent. of enteric fever cases are "carriers," that the evidence so far available indicates that "once a carrier always a carrier," and that the several curative agents and methods do not appear materially to affect the situation.

Reflections of this nature suggest the need for the greatest caution in generalising upon an administrative basis upon certain bacteriological findings, and they show the need for the healthy scepticism which was the dominant note of a critical paper read before the Pathological Section of the Royal Society of Medicine by Dr. W. H. Hamer.³ This problem of "carriers" must continue to be investigated not only by the bacteriologist but also by the epidemiologist, and the more frequently the notes of each are compared the less likely shall we be to be led astray.

House Flies as a Medium of Infection.

There has in the past been a good deal of somewhat loose reasoning as to the part which may be played by the domestic fly in promoting the spread of diseases such as enteric fever and diarrhoa, but before it is possible to make any legitimate inferences upon the subject numerous preliminary observations are necessary. This fact has been fully recognised and acted upon by the medical department of the Local Government Board, which during 1909 issued two very helpful memoranda upon the subject. One of these dealt with the methods of distinguishing the more important species of flies found in houses and with the breeding of the common house fly during the winter months, while the second one discussed the lines of investigation to be adopted, the colouring of flies for purposes of identification, and other matters. This investigation, which is being conducted under the general supervision of Dr. S. MONCKTON COPEMAN and with the cooperation of Mr. JEPSON of the British Museum, Professor NUTTALL, and Dr. G. S. GRAHAM-SMITH, as well as with the assistance of several medical officers of health, should eventually afford us an accurate estimate of the amount of disease due to flies, of the means by which the mischief is brought about, and last, but not least, the remedy.

Small-pox.

With the exception of an outbreak in Bristol during the first half of the year, of sporadic cases in different parts of the country, and of occasional ship-borne cases, the country remained practically free from this disease during 1909 in spite of the large increase in the number of exemption certificates. To those who have studied the epidemiology of small-pox, which the public has not, the fact may appeal, but it has to be borne in mind that the presence of a large number of unvaccinated persons does not in itself create small-pox, and that the only real test of the value of vaccination is the manner in which the disease behaves among the vaccinated and unvaccinated when small-pox is present. It is then that amongst children the unvaccinated are stricken and the vaccinated left, and that amongst unrevaccinated adults the severity of the disease is in inverse ratio to the date and thoroughness of the vaccination. If by a stroke of magic the whole population could be rendered susceptible to small-pox there would not, of necessity, follow an outburst of the disease, and therefore then, as now, the unvaccinated might walk unscathed. But if while the population was in this unprotected state an epidemic of small-pox took place the carnage would not improbably be appalling. If, however, the machinery for vaccination were still in existence and the sanitary organisation which to-day obtains were to be utilised to the full, it is probable that the harvest of disease would be less than in former years. The compulsory notification of the disease and the searching out of unrecognised cases, together with the vaccination of all contacts, would doubtless do a great deal to limit the spread of the malady.

The Prevention of Syphilis.

It is difficult to separate the direct and indirect effects of a given disease, as is well illustrated by the confusion which exists in relation to what are termed the primary and secondary causes of death. It is not easy, therefore, to gauge the precise death-roll of a disease such as syphilis, which is not generally regarded as a malady with at all a high fatality rate. But in the Schorstein lecture delivered in October last the lecturer, Professor W. OSLER, painted with the verbal colours which he employs so attractively what may be the real mortality picture of this malady. Although, as the lecturer pointed out, only some 1658 deaths are debited to syphilis in the Registrar-General's last annual report, it may be necessary to raise this figure to over 6000, and thus to elevate syphilis to "sixth place in the hierarchy of diseases due to specific germs." In order to arrive at this total Professor OSLER takes from the statistical Blue-book the 2332 dead from general paralysis, the 584 dead from locomotor ataxia, half at least of the 1983 dead from paraplegia and of the 2279 dead from softening of the brain, as well as, he thinks, a possible fourth of those who pass out under "other diseases of the nervous system."

But to this grand total the lecturer pointed out there must in all probability be added a considerable proportion of those 1140 persons who died in 1907 from aneurysm, an argument which he brought home with convincing clearness by a disussion of the history of aneurysm in the past and by a review of recent work in connexion with the spirochæta of syphilis discovered by SCHAUDINN and the serological investigations of WASSERMANN. Finally, Professor OSLER placed the ravages by death from syphilis at between 6000 to 7000 annually, exclusive of the uncertain number of stillbirths which may be attributed to the same cause, and to these he added "the thousands maimed and killed by the gonococcus-a David among cocci." With the object of reducing this appalling toll Professor OSLER proposes. inter alia, that venereal disease should be grouped with other infectious diseases and every case registered and supervised. But the other steps which he suggests, such as education on sexual matters, a reduction of "the sight of means," and facilities for early and prolonged treatment are, as he clearly recognises himself, more within the realm of practical politics, and possibly our general hospitals might take a greater share in educational propaganda than they have done in the past.

EXOTIC AND TROPICAL DISEASES.

Knowledge respecting exotic and tropical diseases has continued to advance steadily during 1909. At the present time many important researches are being carried out by individual or collective workers, and much light before long is expected to be thrown upon some at least of the more obscure maladies of exotic origin. Already in some of our colonies and dependencies, as well as elsewhere, practical measures, based on previous scientific research, have been put in force with results that are extremely promising. The future of tropical medicine and sanitation seems to be full of hope and encouragement, and more successes in the war against preventable disease in the tropics are confidently expected in the near future. The "conquest of the tropics" for the white race cannot, to all appearances, be much longer delayed. Below we give a brief account of the behaviour of plague, cholera, yellow fever, and other exotic diseases throughout the world during the past year.

Plague in India.

We drew attention in the Annus Medicus for 1908 to the

to say, has been maintained during 1909. Up to the middle of November, the latest figures obtainable at the time of writing, the fatal plague cases in India in 1909 amounted approximately to 125,000. The figures for the first ten months period in 1908 were 135,545, and in 1907 1,100,000. In three provinces, Eastern Bengal and Assam, Baluchistan, and Coorg, no death from plague occurred, and in the North-Western Frontier Province only a single imported fatal case came under notice. The three provinces which had the highest number of plague deaths in 1909 were the same which suffered most in the previous year-namely, the Punjab, Bombay, and the United Provinces of Agra and Ondh.

At the Medical Congress which met at Bombay early in the year an animated discussion took place on the subject of plague. Among the papers read before the Congress may be mentioned the following: Cats as Plague Preventers, by Lieutenant-Colonel Andrew Buchanan, I.M.S.; The Epidemiology of Plague, by Major S. LAMB, I.M.S., Member of the Advisory Committee on Plague Investigation; Antiplague Inoculation, by Major R. F. STANDAGE, I.M.S.; The Recrudescence of Plague, by Major S. BROWNING SMITH, I.M.S.; The Prophylaxis of Plague, by Captain W. GLEN LISTON, I.M.S.; The Carriage of Plague by Sea, by Dr. G. J. BLACKMORE; and the Clinical Significance of Septicæmia in Human Plague, by Dr. N. H. CHOKSY. Among the other experts who took part in the discussion were Major W. W. CLEMESHA, I.M.S., Captain E. F. GORDON TUCKER, I.M.S., and Dr. J. A. TURNER, medical officer of health of the City of Bombay.

Plague in the Far East.

Only scattered cases of plague were reported in the Straits Settlements and in Siam. In French Indo-China the disease was somewhat widely diffused, for there were epidemics in Cambodia, Cochin China, Tonkin, and in the territory of Quang-Tcheou-Wan, which is leased to France by China. Sporadic cases were also certified in Annam. In China plague was epidemic, especially during the first half of the year, in Canton, where it is estimated about 6000 deaths were due to the disease; also at Kang-Thau, Chang Chew, Amoy, and Swatow. In the latter town and district it is calculated that 2500 deaths resulted from plague during the epidemic in the first six months of 1909. Although cases were notified at Hong-Kong in the first nine months of the year the number was comparatively small. There was no outbreak of human plague at Shanghai, but infected rats continued to be found during a considerable portion of the year. Infected rats were also found in Tientsin, though no prevalence of the disease in man was observed. In Formosa plague was epidemic during the first half of 1909, over 1000 cases being certified. In Japan proper plague was prevalent at Kobe more or less throughout the year, and there was also coincident plague among rats. At Osaka and Yokohama some attacks were notified and infected rats were occasionally discovered; as also at Tokyo and Moji, but without the appearance of any human cases at these last-named places.

Plaque in Oceania.

Some sporadic cases of plague occurred during the year in New South Wales at Sydney and Newcastle, and in most of the instances the appearance of human plague was associated with infection of local rats. In Queensland the disease was reported at Mackay, where there was concurrent plague in rats. At Adelaide in South Australia a small group of cases was notified in the early summer; and at Bunbury, a small seaport town in Western Australia, two coloured seamen were reported as suffering from plague in March. In the Hawaiian (or Sandwich) Islands scattered cases of plague occurred at Hilo, Papaikou, and Olaa. These instances were diminution of plague in India. This diminution, we are glad | associated with coincident plague in rats. A single human

case was reported at Honolulu in the person of a Chinaman recently arrived from Hong-Kong.

Plague in America.

There were only two recognised cases of plague in the United States during 1909, both of them occurring in Almeda County in California. The occurrence of these cases is said to have been associated with concurrent plague among the ground squirrels of the locality. In Contra Costa County, also in California, the presence of plague among ground squirrels was bacteriologically proved, but there were no human cases. At Seattle some rats suffering from plague were discovered from time to time during 1909. In South America the disease was widely diffused. In Brazil plague infection was reported during the year at Rio de Janeiro, Bahia, San Luis de Maranhao, Para, and Pernambuco; in Uruguay at Montevideo; and in Chili at Arica, Antofagasta, Iquique, and Magellones. A considerable number of localities in Peru suffered from plague in 1909, including places in the following departments-viz., Arequipa, Cajamarca, Callao, Lambayeque, Libertad, Lima, Moquegua, and Piura. There was an outbreak of plague in the Pescadores islands and at Guayaquil, the capital of Ecuador, and cases were also reported from Babahoyo, Anigra, Tolte, Nisag, and Chunchi. The plague prevalence which was reported at Caracas, the capital of Venezuela, in 1908, did not altogether abate during 1909. A few cases were notified in the island of Trinidad, at Port of Spain, during the summer.

Plague in Africa.

In Egypt the prevalence of plague, which has persisted for the past 11 years, continued during 1909, Alexandria and Port Said being among the towns which suffered; the majority of the cases, however, occurred in the provinces. In July some deaths from this disease were reported in Zanzibar, and in British East Africa at Kisumu and Port Florence. In German East Africa plague broke out at Muansa, where rats were also affected; six other localities had outbreaks among the local rats, but no human cases. The malady was present in Mauritius during most of the year. No plague was reported in South or West Africa during 1909. In Morocco an epidemic suspected to be plague was raging in the early summer at Mequines, a city in the interior, and it is said that hundreds died from the disease. Later in the year a similar outbreak was reported in the neighbourhood of Saffi, to the south of Casablanca. In August several cases of undoubted plague appeared among the Senegalese soldiers in the French camp at Casablanca. In the Azores group, which lie some 900 miles off the west coast of Morocco, the epidemic of plague which began in 1908 continued up to the middle of 1909, when it subsided.

Plague in Europe and the Near East.

On Feb. 1st Dr. THOMAS CARLYLE PARKINSON, who had been engaged in plague research work at the Elstree branch of the Lister Institute, contracted the disease by accidental inoculation, from which he died on Feb. 4th at the early age of 25 years. There was no extension of the infection, this case forming, so far as we are aware, the only instance of human plague which occurred in the United Kingdom during 1909. There was, however, an outbreak of rat plague at Hull during February, limited fortunately to a single dock warehouse; it was soon suppressed by the vigorous measures applied by the authorities, under the direction of Dr. J. W. MASON, the medical officer of health. In Belgium three mild plague cases were landed at Antwerp in April from a ship which was bringing a grain cargo from the River Plate. These cases were associated with plague infection among the ship rats. Two cases alleged to be plague were reported in Holland at Loosduinen in February, but the diagnosis was officially denied. The only other European country in

Russia, where, in the Kirghiz Steppes of the government of Oural, in June and July a small but extremely virulent outbreak was recorded. Plague was reported during the year in several localities in Turkish territory, including Beirut, Alexandretta, Adalia, Jeddah, and Bagdad. A single case occurred at Mecca in January, the person attacked having travelled from Jeddah with the infection upon him. In the Bahrein Islands, off the Arabian shore of the Persian Gulf, cases were notified in May and June; and at Muscat shipborne plague was reported in April. At the Persian port of Bushire an outbreak occurred on a steamer from Bassorah, three persons having died from the disease during the voyage and seven others having been subsequently attacked and treated at the lazaret on shore.

Cholera in Russia.

Cholera continued to be prevalent in Russia during 1909, more especially in St. Petersburg and district. A number of ports in the Baltic Sea were also infected, including Cronstadt, Viborg, Narva, Reval, and Riga. The port and district of Archangel in the White Sea were invaded by the disease, as were also many inland towns and districts in Central and Western Russia. The majority of the grain ports in Southern Russia, which had suffered in 1908, escaped from the ravages of cholera during 1909. Outbreaks were reported at Baku on the Caspian Sea, at several places in Siberia, and at Vladivostock. So far as can be ascertained the total number of cholera attacks notified in Russia up to the end of November, 1909, was about 20,000, and of these nearly 9000 proved fatal. Of this number, over 6000 cases and 2400 deaths occurred in the city of St. Petersburg, where the disease has been epidemic practically without a break for the last 18 months.

Cholera in Europe elsewhere than in Russia.

From Russia cholera was carried on shipboard to certain European ports, including Stockholm, Vardoe (Norway), Elsinore (Denmark), and Rotterdam, but in none except Rotterdam did the infection spread. Several ships arrived at Rotterdam during the autumn from North Russian ports with a cholera case or cases on board, and other vessels pumped out into the harbour water ballast obtained from specifically polluted Russian rivers. In this way the waters of the Maas at Rotterdam became contaminated, and since a number of persons engaged on river craft use this water for domestic purposes some of them contracted cholers. Altogether 34 cases and 15 deaths were recorded in Rotterdam during the autumn. From this port the infection was carried up the numerous canals and waterways into the interior of Holland, scattered cases being notified at Amsterdam, Utrecht, Pernis. Gorinchem, Hoogvliet, Vlaardingen, Middleburg, Breda, Halsteren, Lopik, Hattem, Dordrecht, Tholen, Nithorn, Dirksland, and Jaarsveld. Just over the Dutch border some suspected cases were reported in Belgium territory on board a boat from Utrecht, at Lillo on the banks of the Scheldt, and shortly afterwards an outbreak of cholera comprising 10 cases and 6 deaths occurred at Boom, a town on the River Rupel, a tributary of the Scheldt, ten miles from Antwerp. Cholera was conveyed from Russia by rail over the German border into East Prussia, and other cases occurred along the course of the Memel and other smaller rivers which pass from Russia through East Prussia to the Baltic. Altogether about 33 cases were notified in this German province during the autumn, the places affected including Königsberg, Pokallna, Stoltzenhagen, Tilsit, Russ, Andreischken, Skirwietell, Labiau, Sköpen, Hydekrug, Kurkau, and Nemonien.

Cholera in England.

ship rats. Two cases alleged to be plague were reported in Holland at Loosduinen in February, but the diagnosis was officially denied. The only other European country in which, as far as is known, plague occurred during 1909 was in the Baltic. A sick sailor was landed at the port hospital

where he died, the cause of death being proved by bacteriological examination to be cholera. As evidence that our port authorities are on the alert we may mention that a Russian captain was fined £23 3s., including costs, for allowing persons to land from his ship in the Port of London without leaving their names and the addresses to which they were proceeding. In a similar instance an English captain was fined £10 for a like offence on the arrival of his vessel from Rotterdam.

Cholera in India.

In India, where cholera is always present, the disease was epidemic in a number of localities and more especially in the provinces of Bombay, Bengal, Madras, and Eastern Bengal and Assam, as well as in the native State of Hyderabad. In the city of Bombay the number of cases notified was higher than in the previous year. At Calcutta a very regrettable outbreak occurred at the end of July in the European General Hospital affecting chiefly the European nurses, 13 of whom were attacked within a period of 36 hours, 7 of them dying after an illness which lasted only about 24 hours. A Government inquiry, conducted by Professor M. W. HAFF-KINE, Major W. W. CLEMESHA, I.M.S., and Dr. FREDERICK. T. PEARSE, medical officer of health of the city, showed that the outbreak was due to the handling of milk and other food by two native kitchen servants whose hands at the time of the inquiry were still infected by cholera organisms. One of these men, indeed, proved to be a chronic "carrier" of cholera, and he was passing daily in his stools large quantities of the specific microbes of the disease, although he himself appeared to be in good health.

Cholera in the Far East.

Outbreaks of cholera were reported at Bangkok in Siam, and at Singapore in the Straits Settlements. In Indo-China the disease appeared in Annam, Cambodia, Cochin China, Laos, and Tonkin; and in the Dutch East Indies there were epidemics at Djambi in the island of Sumatra, and at Batavia in the island of Java. In the latter of these places over 2000 fatal cases were certified in the period from July to October. A widespread prevalence of the disease was present in the Philippine Islands, no fewer than 3000 deaths being registered from this cause during the first eight months of the year. Manila did not escape the infection, but the cases reported did not occur in any large numbers.

Yellow Fever in South and Central America.

Yellow fever was prevalent in certain parts of Brazil, more particularly in Para where 121 persons lost their lives from it, and at Bahia where also about as many died from the disease; smaller outbreaks occurred at Manaos and Pernambuco. At Rio de Janeiro, where formerly yellow fever was frequently epidemic, only a single, non-fatal case was notified, and this was presumably an imported instance. In THE LANCET of August 7th we commented upon a report by Dr. RANGEL PESTANA entitled "Comment on Assainit un Pays," being an account of the extinction of yellow fever in Rio de Janeiro, and showing how from an annual average of 1731 deaths from this dangerous malady during a period of 13 years prior to 1903, when measures for the destruction of the stegomyia fasciata were first begun, the fatal cases had fallen to 42 in 1906. 39 in 1907, 4 in 1908, and none in 1909. A similar experience has been shown in Santos where anti-stegomyia measures have been carried out and not a single death from yellow fever has been registered since 1904. Some sporadic cases of this disease occurred during 1909 at Carthagena in the republic of Colombia, at Parimaribo in Dutch Guiana, and at Suddie in British Guiana. At Ancon in the Panama Canal Zone two vessels arrived, each carrying a single case of yellow fever. In this connexion attention may be drawn to a pamphlet on the "Prophylaxis of Yellow Fever," prepared by Dr. G. M. GUITERAS, whose

name is honourably associated with the campaign against this disease, and on which we commented in THE LANCET of June 26th.

At Guayaquil in the Republic of Ecuador yellow fever was epidemic in the first half of 1909, causing about 200 deaths. Among those who lost their lives from the disease was Dr. WILLIAM MARTIN WIGHTMAN, passed assistant surgeon of the Public Health and Marine Hospital Service of the United States, who had been detailed for duty at Guayaquil since April, 1908. In Mexico yellow fever was prevalent in the early months of the year in Vera Cruz, Merida, and other districts. A claim has been advanced by Dr. HAROLD SEIDELIN, professor of bacteriology in the Medical School at Merida, that he has isolated and identified the specific parasite of the disease, which he has found, he says, in the red corpuscles of the blood. He is disposed to classify this parasite among the piroplasmata. Further confirmation of these observations by other competent experts is necessary before they can be accepted, and their presence in the stegomyia will also have to be demonstrated. In the Republic of Venezuela yellow fever outbreaks were reported at Maiquetia and Ciudad Bolivar during the summer months.

Yellow Fever in the West Indies.

After freedom from yellow fever for over 20 years, the island of Barbados experienced an outbreak of the disease at the end of 1908, and from that date to August, 1909, some 87 cases and 37 deaths were recorded. No cases occurred among the visitors to the island or among the foreign seamen, but the outbreak was entirely confined to the native-born Barbadians. Sir RUBERT BOYCE, at the request of the Colonial Office, visited Barbados and the West Indian Islands to advise the local authorities as to measures for preventing the spread of the disease. In THE LANCET of June 26th we drew attention to his recommendations, which were also discussed by him in an address given on July 8th under the auspices of the West Indian Committee in London.

Some scattered cases of yellow fever were reported in the Dutch island of Curaçoa, in Trinidad at Port of Spain, and in the French colony of Martinique at Fort de France. A few cases also occurred in Cuba, but the disease may be said to be practically extinguished in that island. An account of the Cuban measures was presented to the International Medical Congress at Budapest by Professor AGRAMONTE of Havana, in which he claimed that the results had been entirely satisfactory, and that yellow fever had been "stamped out" in Cuba.

Yellow Fever in Europe.

In the Annus Medicus for 1908 we drew attention to the occurrence of yellow fever in France at the Port of St. Nazaire in that year, the infection having been brought on shipboard from Martinique. A similar instance occurred in May, 1909, yellow fever having been brought by the s.s. Lanfrano from Brazil to Portugal. Seven cases, four of them fatal, had occurred on this vessel after leaving Manaos before its arrival at Lisbon, where two of the surviving cases, both German passengers, were landed for treatment at the por. hospital, where each made a good recovery. Fortunately, there was no extension of the disease, all the necessary precautions having been taken. The Lanfrano reached Liverpool on June 3rd, when all on board were found well. Fortunately, when this vessel arrived at Lisbon the weather was comparatively cool, the temperature ranging from 50: to 60° F., so that the conditions for diffusion of the disease were unfavourable; but the result might have been otherwise if the ship had reached Europe during hot weather.

Malta or Mediterranean Fever.

The form of fever caused by the micrococcus melitensis is now said to be practically extinct in the naval and military garrisons of Malta, though it continues to be prevalent among the civil population, many of whom scoff at the simple precaution of boiling goat's milk before consuming it. While the true Malta fever has thus been reduced, there is another, though less severe, form of illness termed the "three days" fever" which is prevalent in the island, as well as in other Mediterranean stations. To investigate this a committee of army surgeons was appointed by P.M.O. Colonel J. G. MACNEECE, R.A.M.C., with the result that the cause was found to be an infection transmitted by the bites of the midge owl (Phlebotomus papatasii) which constitutes a veritable pest in Malta and elsewhere during the hot season. An experiment was made on the person of Lieutenant H. G. GIBSON, R.A.M.C., who volunteered to submit to be bitten by specimens of these insects which eight days previously had fed on a patient during the first day of the disease. A week later Lieutenant GIBSON was seized with the usual symptoms of the three days' fever-vomiting, severe pains in the head, back, and limbs, with rise of temperature lasting three days. Similar experiences had already been reported by Dr. R. Doerr in Bosnia and Herzegovina. The specific organism of the disease, however, has yet to be discovered.

Epidemio Cerebro-spinal Meningitis.

Epidemics of cerebro-spinal meningitis have occurred during 1909 in various parts of America; in France, at Paris and other places in the Department of the Seine, and at Evreux and elsewhere in the Department of the Eure. Other outbreaks have been reported in Switzerland, Italy, and Austria. In Prussia up to the end of October 950 cases had been notified, with 402 deaths, a case-mortality of 42.6 per cent.; in the previous year 1226 cases and 530 deaths were reported, giving a case mortality of 43.2 per cent. It is interesting to mention that in Westphalia, and also at Leyden in the Netherlands, epidemics of what is termed "infantile paralysis" occurred during the year, but whether these outbreaks were related to epidemic cerebro-spinal meningitis it is not possible to say. Something of the same sort is said to have occurred in certain parts of the United States, including Chicago. In Cyprus a widespread prevalence of cerebrospinal meningitis was reported by Dr. G. A. WILLIAMSON, acting chief medical officer of health. Beginning in December, 1908, and extending to the end of May, 1909, no fewer than 1153 cases and 600 deaths were certified, yielding a case mortality of 52 per cent. The disease also occurred in Constantinople and in the Arabian province of Assyr. In Japan, at Yokohama, and other places outbreaks were also reported.

There is a growing opinion that the treatment of this malady by intraspinal injections of anti-meningococcic serum offers the best chance of recovery. The serum of FLEXNER and JOBLING still enjoys a high reputation, especially in America, where it is claimed that the case mortality has been reduced from over 70 to 20 per cent. In Germany Kolle and Wassermann's serum is preferred, and in France a serum prepared at the Pasteur Institute by M. DOPTER, on a principle suggested by M. ROUX, has been recently used with good results. This serum is obtained by immunising horses by means of living cultures and not by microbial extracts. In Austria a plan for preventing danger from "carriers" of the meningococcus by spraying and washing out their nasal cavities with pyocyanase has been abandoned, as the specific microbes of the disease could be shown to persist in the nasal passages for weeks, notwithstanding the use of the remedy.

Sleeping Sickness.

The year 1909 has seen a considerable advance in our knowledge of this disease, and for information as to this we are largely indebted to the London Sleeping Sickness Bureau, which was established late in 1908. The director of the bureau, Dr. A. G. BAGSHAWE, acts also as editor of the

monthly bulletins, which contain valuable summaries of the more important contributions made from time to time by investigators of trypanosomiasis at home and abroad. More especially do these bulletins make public the work done by the Commission appointed by the Royal Society and which went out to Uganda under the leadership of Colonel Sir DAVID BRUCE, F.R.S., about the end of last year. One important work which this Commission has already done has been the repeating and confirming of the experiments made by Professor F. KLEINE, which suggest that the parasite of sleeping sickness undergoes a cycle of development in the body of the Glossina palpalis. In the columns of THE LANCET we have frequently during the year directed the attention of our readers to the more interesting contributions summarised in these monthly bulletins. In a paper read before the Society of Tropical Medicine and Hygiene on Oct. 22nd, and published in full in THE LANCET of Oct. 23rd, Dr. BAGSHAWE gave a résumé of the Advances of our Knowledge of Sleeping Sickness which had been made within the last 12 months, affecting specially our knowledge as to the transmission, means of diagnosis, clinical characters, treatment, and prophylaxis of the disease. During the year the report of the French Sleeping Sickness Commission by M. MARTIN, M. LEBŒUF, and M. ROUBAUD has been published, as also that of the German Commission by Professor R. Koch, Professor M. BECK, and Professor F. KLEINE. In THE LANCET of Oct. 30th we summarised the main points of the latter report.

Dr. ALLAN KINGHORN, of the Liverpool School of Tropical Medicine, who had been investigating sleeping sickness in North-Eastern Rhodesia and Central Africa, and who published in THE LANCET of Sept. 25th a paper on the Trypanosoma Dimorphon, has now proceeded, at the request of the Secretary of State for the Colonies, to West Africa to investigate the disease there with a view of framing recommendations for the prevention of its spread in that region.

It is with great regret that we record the death, on March 8th, of Captain FRED HALLAM HARDY, R.A.M.C., from sleeping sickness, at Aden, whither he had gone after contracting the disease, it is said, in Nyassaland, where he had been at work under the Commission. This adds another to the many medical men who have died as martyrs to scientific research.

Beri-beri.

The subject of beri-beri has been brought prominently before the public during 1909 by questions asked in Parliament about deaths from the disease on board ship, by letters in the public press, and by discussions and papers in our scientific societies. The questions in Parliament related chiefly to occurrences of beri-beri on ships arriving in this country from foreign ports, and as to deaths of Lascars from this disease. It was suggested in the House of Commons that a commission should be appointed to investigate the causation of beri-beri, but the matter was ultimately allowed to drop. In the Shipping Gazette a number of articles on the disease by ships' officers and others were published, but these did not throw any fresh light upon the subject. In THE LANCET of Feb. 13th we published a preliminary report by Dr. HENRY FRASER and Dr. A. T. STANTON of the Institute for Medical Research, Kuala Lumpur, Federated Malay States, who produced evidence showing that beri-beri in the Malay Peninsula was intimately associated with the consumption of white or "uncured" rice. We commented in THE LANCET of August 7th on the detailed report of these two investigators, but we are still awaiting the final results of the further inquiries which are being made by them. The white rice theory was brought under the notice of the Society of Tropical Medicine and Hygiene by Dr. W.

LEONARD BRADDON in a communication read on April 16th and discussed at that and the subsequent meeting in May. Dr. Braddon has for some years contended that the use of white rice was the main cause of beri-beri. subject was also discussed by him and others at the Medical Congress which met at Bombay early in the present year. In the Shipping Gazette, in one of the articles referred to above, a list of ships known to have arrived in this country with beri-beri cases on board during each of the last five years was published on Oct. 30th, and from this it appears that during the present year over 60 cases had been landed from eight ships up to October, and of these 9 or 10 had terminated fatally. The disease is known to be not infrequent on board Norwegian sailing ships on long voyages. One such ship reached Falmouth from the South Sea Islands in October with 10 sufferers on board, and some excitement was aroused in the Tyne by the arrival there of a Brazilian man-of-war with some 25 cases on board. Apart from such ship-borne instances, beri-beri is not often seen in Great Britain.

Malaria.

The subject of malaria was discussed with some earnestness, not to say acrimony, at the Medical Congress which met at Bombay early in the year, the debate ultimately bearing good fruit. For owing in part to the prominence given to the question at the Conference, the Government of India called together at Simla in October a conference of Indian experts on malaria with a view of obtaining information as to the distribution of the disease and the measures best adapted in different parts of the country to prevent its occurrence. Fuller references to both the Congress and the the Conference will be found in the section dealing with the scientific work of the Naval, Military, and Indian Medical Services. Malaria, we hear quite recently, has of late shown a tendency to increase in the port of Bombay. The story of malaria in Mauritlus was told in the report of Professor Ross and Major C. E. P. Fowler, R.A.M.C., and we discussed it in THE LANCET of March 27th. We drew attention in our columns of July 24th to a puzzling outbreak of malaria in an island of the Seychelles group, which raised the question if this disease could ever occur without the agency of anophelines. In this con. nexion we may mention that in the annual report for the year ended March 31st, 1909, on the Bechuanaland Protectorate, the fact is stated that malaria prevails in the almost waterless Kalahari Desert, where the few water-holes that exist are often a hundred miles or more apart, and where consequently it is scarcely possible that anophelines can be bred in any numbers. The suggestion is therefore made that in the Kalahari there is probably some other transmitter of the malaria parasite than the mosquito.

A national league against malaria has been founded in Italy under the presidency of Professor Baccelli with Senator Golgi as chairman of the local organising committee, which, in addition to the two names already given, comprises Professors Lustig, Gossio, Gobbi, Di Mattei, Canalis, Dr. Picchi, and others. Professor Baccelli proposes that a national, or better still an international, congress on malaria should be held in Rome in 1911.

The possibility of malaria spreading in our own country under certain conditions cannot be ignored. Captain P. S. EASTON, R.A.M.C., has recently published in the journal of his corps the case of a young soldier, born and bred in London, who had never been out of England, but who was attacked, after a few months' residence in camp at Aldershot, by illness proved by examination to be malaria, the parasites having been found in the blood. He remembered being bitten on the wrist by a "gnat" about a month before removal to hospital. Anophelines, it may be added, have already been observed at Aldershot, where also there are

living a number of men returned from foreign service who have had malaria, and whose blood therefore at times may furnish parasites to infect local mosquitoes.

Blackwater Fever.

During the year reports of two scientific investigations of blackwater fever have been made public. The first of these related to an inquiry, undertaken at the instance of the Government of India, by Captain S. R. CHRISTOPHERS, I.M.S., and Dr. C. A. BENTLEY, and which was conducted in an intensely malarious district at the foot of the Himalayas between Nepaul and Assam. The report was issued as No. 35 of the Scientific Memoirs of the Medical and Sanitary Departments of the Indian Government. The second investigation, financed jointly by the Colonial Office and the Liverpool School of Tropical Medicine, was carried out in Nyassaland by Dr. J. O. W. BARRATT and Dr. WARRINGTON YORKE. The report was published in the Liverpool Annals of Tropical Medicine and Hygiene. Both reports throw considerable light on the causes which combine to bring about the condition known as blackwater fever.

African Entomological Research.

The relationship which exists, particularly in Africa, between biting insects and the spread of certain diseases in man and animals has at last been recognised by the British Government, for in August of this year the Secretary of State for the Colonies appointed a special African Entomological Research Committee which is to investigate the above relationship, as also that of biting insects to economic plants and their cultivation. The committee comprises a number of well-known entomological experts, and among the medical members we may mention the names of Sir PATRICK MANSON, F.R.S., Colonel Sir DAVID BRUCE, F.R.S., Colonel A. W. ALCOCK, F.R.S., Colonel D. PRAIN, F.R.S., Dr. ROSE BRADFORD, F.R.S., Professor G. F. NUTTALL, F.R.S., and Dr. A. G. BAGSHAWE. Much good work in the way of research has already been done by the staff of the Natural History Department of the British Museum as regards mosquitoes and the tsetse flies. During 1909 Mr. E. E. AUSTIN of that staff brought out a very valuable volume on "African Blood-sucking Flies," on which we commented in an article published in THE LANCET of Sept. 18th.

Advisory Committee for Tropical Africa.

During the year the departmental committee appointed to investigate the complaints which had been made with regard to the West African Medical Staff presented their report, and this was duly considered by the Secretary of State for the Colonies, along with the recommendations which were put forward for the improvement of that service. As a result the Colonial Office have nominated an advisory committee on medical and sanitary questions connected with the British Colonies and Protectorates in tropical Africa. The committee consists of eight members, two of whom, including the chairman, represent the administrative staff of the Colonial Office, while the remaining six are medical men, viz., Sir Patrick Manson, K.C.M.G., F.R.S., Sir Rubert BOYCE, F.R.S., Dr. THEODORE THOMSON, C.M.G., Dr. W. T. PROUT, C.M.G. (late P.M.O. Sierra Leone), Professor W. J. R. SIMPSON, C.M.G., and Dr. J. K. FOWLER, late Dean of the Faculty of Medicine, University of London.

FORENSIC MEDICINE.

THE DEVELOPMENT OF WORKMEN'S COMPENSATION,

This section of the Annus Medicus is largely taken up with cases arising out of "workmen's compensation." The list of cases might easily have been made longer, as all who read our columns know, but the decisions quoted are those in which the issues raised have depended most intrinsically on medical evidence, and which best illustrate the probable relevancy of medical evidence on future occasions. The

working of the Act is causing considerable anxiety. It provides compensation for many upon whom the incapacity arising out of accident or industrial disease has before pressed with undue severity, but it is open to the criticism that at times it lays a burden opon employers not always consistent with strict justice. By a section of the Act itself the serious and wilful misconduct of the workman does not disentitle him or his dependants from compensation at his employer's expense if it has brought about his permanent disablement or death, and it appears to be now well established by judicial authority that the absolute physical unfitness of the employed person for the work undertaken by him does not prevent the natural consequence of such unfitness from ranking as an accident.

Some Interesting Actions At LAW.

Bellerby v. Heyworth and Bourn.-Three persons entered into partnership to practise dentistry, none of them being qualified, under articles of partnership which stipulated that no partner should do any act calculated to infringe the Dentists Act. Two of the partners displayed a notice on the premises where they carried on business, "Bellerby. Heyworth, and Bourn. Finest Artificial Teeth. Painless Extraction. Advice Free. Mr. Heyworth attends here.' In an action by the third partner for a dissolution of the partnership Mr. Justice PARKER held that the above constituted a breach of the articles and made an order dissolving the partnership. The Court of Appeal reversed this decision on the ground that there was nothing in the Dentists Act to prevent an unqualified person from doing dentist's work and from informing the public that he was prepared to do so, and that the notice did not go further than to announce that the members of the firm would do that which the law permitted them to do. The words "painless extraction" were not construed by the court as implying the possession of special qualifications within the meaning of the Act.

Etherington v. The Lancashire and Yorkshire Accident Insurance Company .- This was an appeal to the Court of Appeal from the decision of Mr. Justice CHANNELL upon a case stated for argument before the former by arbitrators under a clause in the accident insurance policy. A gentleman, deceased, died from pneumonia as the result of riding home after meeting with a hunting accident which did not otherwise injure him. It was contended on behalf of his widow that the onset of pneumonia due to the lowering of the vitality of the deceased by the accident entitled her to payment under a policy of insurance against "bodily injury caused by violent, accidental external and visible means, in spite of a clause, set up by the defendants, which denied compensation where the direct or proximate cause was disease or other intervening cause, even although the disease might itself have been "aggravated by such accident or have been due to weakness or exhaustion consequent thereon, or the death accelerated thereby." The Court of Appeal upheld the decision of Mr. Justice CHANNELL who had decided that the death was caused by an accident within the meaning of the policy.

The Attorney-General v. G. C. Smith, Limited.—A company was formed in 1906 to carry on the business of G. C. Smith, whose name had been struck off the Dentists Register in that year. The above action was brought at the instance of the British Dental Association against the company and G. C. Smith, the sole director, to restrain the company from representing that they were carrying on the business of a dentist or surgeon dentist as successors to G. C. Smith, or that they were dentists or dental practitioners, and from using any name, title, or description implying that they were registered under the Dentists Act, 1878. An injunction was granted in the Chancery Division by Mr. Justice Swinfen Eady to the above effect.

Hillyer v. The Governors of St. Bartholomen's Hospital.—
The plaintiff, a medical man, brought an action against the defendants for damages for personal injuries alleged to have been sustained through the negligence of their servants (the surgeons and nurses at the hospital) in the course of an examination, during which the plaintiff was placed under an anæsthetic. The plaintiff's case was that his arms had been allowed to hang down and had come in contact with the heating apparatus and had been burnt. Mr. Justice Grantham held that there was no evidence of negligence to go to the jury, and the question of the liability of the governors of hospitals in such cases did not, therefore, have to be decided. Mr. Justice Grantham's view was upheld on appeal.

Two Actions against the London Hygienic Institute. - In the case of Hawthorne v. The London Hygienic Institute the plaintiff, a baker, sued the defendants, a firm carrying on the practice of dentistry through paid assistants, not qualified, for damages for personal injuries caused by their negligence in the extracting of the plaintiff's teeth. Cocaine was injected, but the plaintiff denied that it prevented him from feeling pain, and 22 teeth were extracted at a sitting, after which the defendant suffered severely from faintness and hæmorrhage, requiring the attendance of a medical man and of a qualified dentist, the latter of whom removed 14 stumps which had been left in the plaintiff's jaw. The jury awarded £50 damages. In another action against the same defendants the plaintiff, a woman, came up from the country to have her teeth attended to at the Hygienic Institute, where an employé, a person not qualified except by seven years' experience in pulling out teeth, extracted five teeth at one sitting and 11 on the following day, injecting cocaine into her gums, with the result that she suffered from cocaine poisoning. After this case had been partly heard it was settled upon terms which were not stated in court.

Action on a Warranty of Milk as Free from Borio Acid. - In an action tried at the Croydon county court the plaintiff recovered damages against a dairyman for supplying milk for the consumption of his infant daughter containing boric acid in breach of a verbal warranty that the milk should be free from any preservative or adulteration. The plaintiff had before ceased to deal with another dairy on account of the presence of preservatives in the milk sold, and he stipulated that there should be none in arranging to be supplied by the defendant. The child when fed on the milk suffered from diarrhoea, loss of appetite, and loss of weight, and after its discontinuance improved in health, analysis showing in a sample of the milk delivered by the defendant boric acid in the proportion of five grains to the pint. The damages were assessed at £11 1s. 6d., the actual cost to the father, and £5 5s. for the child in respect of her suffering, and judgment followed for the above amount with costs.

"Dr." Bodie.—A person calling himself "Dr. Bodie' was sued by a young man named IRVING to recover damages for misrepresentations which had induced him to pay to the defendant £1000 in consideration of Bodie, whom he understood to be a qualified medical practitioner, teaching him "hypnotism, bloodless surgery, and medical electricity," and disclosing to him secret methods which Bodie professed to make use of in stage performances and exhibitions on the stage at music halls and other places of entertainment. He stated that Bodie had only shown him in return for his money tricks by which he imposed upon audiences, and after a prolonged trial, in which scientific and other evidence was given as to the nature of the defendant's supposed demonstrations of skill, the jury awarded the defendant the damages claimed by him.

WORKMEN'S COMPENSATION ACT.

The Working of the Act in 1908.—A Blue-book containing statistics relating to the Workmen's Compensation Act, 1906,

during the first complete year of its operation (1908) showed that in that period compensation was paid in 26 cases of death and 2260 cases of disablement. Among these there were 421 cases of lead poisoning, 23 of anthrax, 15 of arsenic poisoning, and 10 of compressed air illness. Up to the end of 1908 there were 344 medical referees appointed for England, Scotland, and Ireland, to whom 272 references were made. Of these 136 were made by judges, 43 by arbitrators, and 93 by committees. There were 35 appeals against certifying surgeons, in which 20 of the decisions appealed against were upheld and 15 were not.

Workmen's Compensation Act: Cases in the Court of Appeal. Cerebral Hæmorrhage through Lifting a Weight .- In Scotland the Court of Session heard an appeal by the defendants against a claim by a workman successfully made before the Sheriff-Substitute. The workman, whose arteries were in a degenerate condition, had an attack of cerebral hæmorrhage while moving a weight, and having been put to bed had a second attack four days later causing permanent paralysis. Held, that the case coincided in principle with Stewart v. Wilsons and Clyde Coal Company (5 F. 120), and with cases relating to rupture in respect of the question whether the injury was due to accident. Also, that in the absence of evidence to the contrary the two attacks were due to the same cause, and that the workman was entitled to succeed.

Murphy v. Enniscorthy Board of Guardians (42 Ir. L. T. 246). — The Court of Appeal in Ireland was asked to decide whether a dispensary medical officer (who had been thrown from his trap and killed while in discharge of his duty as such) was a workman within the meaning of Section 13 of the Act. Held, that there was no "contract of service or apprenticeship with an employer by way of manual labour, clerical or otherwise," such as would bring the deceased within the meaning of the section.

Charles v. Walker, Limited.—The widow of a deceased workman claimed in respect of his death, which took place while he was recovering from an anæsthetic administered to him for the amputation of a finger injured by an accident, and renewed in order that a tooth might be removed of which he had complained. The county court judge had found that it was at least as probable that death had been due to a spasm caused by an attempt to swallow blood oozing into the mouth as that it was due to the anæsthetic administered for the first operation, and decided that consequently the widow had not made out her case. The Court of Appeal held that the county court judge had "rightly directed himself" and that the claimant had failed to discharge the onus which lay upon her to prove the facts upon which her claim depended.

Griffiths v. the Istradoren Colliery Company.-The claimant, a collier, injured his knee while at work, and owing to the accident took more than two hours to reach his home on a cold day, thus contracting pneumonia which resulted in bronchitis and chronic asthma. The county court judge found that the workman's incapacity due to the pneumonia was not the natural result of the accident and refused the compensation claimed. The Court of Appeal held that this was wrong, and in remitting the case to the county court judge laid down as a principle that the true question was not what might be the reasonable or probable or natural result of the accident, but whether the condition complained of was in fact the result of it.

Hughes v. Glover, Clayton, and Co. - In this case a workman employed by a firm of shipbuilders fell dead when tightening a nut with a spanner. Post-mortem examination showed that death was caused by the rupture of a large aneurysm of the aorta, and medical evidence was given to

any time in the condition in which the man was, or that it might even have occurred in sleep. The county court judge awarded compensation to the dependents on the ground that the death was due to an accident within the meaning of the Act, and the Court of Appeal upheld the decision, holding that the injury was the result of the work in which the deceased was engaged, and that the case came within the principles laid down in Williamson v. Ismay, Imrie and Co. (death of a ship's fireman from heat-stroke held to be an accident), and Stewart v. Wilsons and Clyde Coal Company.

Lead Poisoning Contracted at Sea. - A seaman claimed against a firm of shipowners in respect of lead poisoning contracted in painting their ship at sea. Held by the county court judge, and confirmed by the Court of Appeal, that the Act did not apply to lead poisoning contracted in the painting of a ship at sea, as it only supplied machinery for obtaining compensation for industrial diseases where there was a district with a factory surgeon to certify when they occurred, and apparently did not contemplate or provide for such cases occurring elsewhere than within such districts.

Refusal to Undergo a Surgical Operation. —A seaman claimed compensation for injuries involving the loss of a finger, which was originally accidentally burned, after which it became septic. The man submitted once to having the finger lanced by the ship's surgeon, but when on the following day the making of two or three further incisions was suggested he refused to submit, and in the end the finger had to be amputated. The county court judge was of opinion that the operation might have been undergone and would have saved the finger, but he felt himself bound to take into consideration the evidence of a medical witness who had expressed the opinion that the rejected operation would not have saved the finger, and in the circumstances he was not prepared to find that the defendant was unreasonable. This decision the Court of Appeal declined to disturb.

Workmen's Compensation Act: Decisions of County Court Judges.

Contribution by Employers in a Case of Lead Poisoning .-In a case at Bury in which the workman, a painter, claimed in respect of lead poisoning, and the judge found that it had been contracted gradually during a period in which the workman had been in the service of five different firms at different times, an award was made for weekly payment during incapacity to be divided into twenty-sixths and to be paid by the firms in proportion to the number of weeks during which they employed the claimant.

Rupture and the Duration of Incapacity.—In the Liverpool county court a ship's cook claimed compensation as for permanent incapacity on the ground of rupture sustained at sea. Evidence was given that a large proportion of ruptured men applying to be passed as medically fit for service at sea were so passed, and the judge awarded half wages up to the date of the hearing, to be followed by 1d. a week, the latter being allowed in order that the matter might be kept open.

In the same county court a ship's fireman claimed compensation on similar grounds. Medical evidence as to the passing of ruptured men wearing trusses for sea service was given, and it was argued on the other side that the nature of the claimant's work would be liable to cause shifting of the truss and renewal of the injury with possibly serious results; also that the wearing out of the truss would be a continual source of expense. The award was for half wages up to the date of hearing followed by 2s. per week.

Cleland v. Burrell and Son. - In the Belfast Recorder's court an application was made for compensation by the widow of a chief engineer on board a ship belonging to the the effect that very slight exertion might have caused it at | defendants on the ground that dysentery, from which he had died at sea, was an accident within the meaning of the Workmen's Compensation Act, 1906. The case of Williamson v. Ismay, Imrie and Co. was relied upon. The judge held that dysentery was not an accident within the meaning of the Act.

CRIMINAL CHARGES, CASES IN THE POLICE COURTS, AND INQUESTS.

Conviction of Three Prisoners in a Case of Abortion.—Two men and a woman were convicted at the Old Bailey, one of the former for performing, and the other man and the woman for aiding and abetting him in the performance of, an illegal operation. Of the two accomplices, the man took his servant, who had become enceinte, to the woman, who in turn introduced her to the principal criminal, who was known as "Dr." Jones, and whose name had been removed in 1902 from the Medical Register after a conviction for performing an illegal operation. Jones was sentenced to ten years' penal servitude, the second man to three months' imprisonment in the second division, and the woman was bound over to come up for judgment if called upon.

A Prosecution under the Midwires Act.—In the case of a midwife charged with fraudulently procuring admission to the Midwives Roll, a medical practitioner was charged with knowingly aiding in the commission of the offence. The latter had certified personal knowledge of the former and of her good character since 1889, but it was found that in 1892 and in 1898 she was tried on charges arising out of alleged illegal operations. The case against the medical man was dismissed on the ground that he acted carelessly only and did not knowingly commit the offence with which he was charged, the magistrate observing that the Director of Prosecutions was amply justified in the course he had taken in prosecuting and in calling on the medical man to explain his conduct.

Coroners' Inquests and Scientific Ecidence. At an inquest held at Southwark Dr. F. J. Waldo called attention to the lack of power on the part of coroners to obtain scientific evidence beyond that contemplated by the Coroners Act, 1887, by which a coroner having decided to hold an inquest, but not before so deciding, may order a post-mortem examination with an analysis of the contents of the stomach or intestines, and may pay 1 guinea for it, with another fee of the same amount if evidence is given. In the case before Dr. Waldo it was a question of bacteriological examination in order to ascertain whether the deceased had or had not died from Asiatic cholers.

" Christian Science."-The death of Colonel CHARLES ALEXANDER, a retired military officer, was the occasion of an inquest at which it was proved that the deceased died from syncope following acute blood poisoning, the result of varicose ulcers on his legs, for which he had refused all medical treatment, employing a "Christian Science healer." A feature in the case was the calling in of a medical man by the healer, or by the relatives on her advice, the object of so doing being possibly to obtain a medical certificate in the event of death. As a matter of fact, death was imminent when the medical man saw the patient, and at that period he could have done nothing to avert it. He was not asked to give any treatment, however, but only to diagnose the case. A medical witness who made a post-mortem examination informed the jury that if taken in reasonable time the ulcers would have been amenable to medical treatment and that in his opinion the absence of such treatment accelerated death. The jury found a verdict in accordance with the medical evidence and laid the responsibility of refusing medical aid upon the deceased.

A Fatal Fire at a Hairdresser's.—An inquest was held at the Westminster coroner's court on the bodies of two women, 22 and 18 years of age respectively, who were fatally burned at a hairdresser's establishment. The younger woman was an assistant in the hairdressing business and the other had gone

to the shop to have her hair dressed. In the absence of the wife of the proprietor, whose injuries prevented her from giving evidence, it was not definitely ascertained how the fire took place, but the evidence pointed to the ignition of petrol vapour through the upsetting of a lamp containing methylated spirit. The room, or one opening into it, had appaently been used for the purpose of cleaning false hair with petrol, or for shampooing with it. The jury found a verdict of "death by misadventure caused by the upsetting of a methylated spirit lamp used by Mrs. RAFFNER (the surviving woman), there not being sufficient evidence of a petrol shampoo having taken place on that occasion."

The Dry Shampoo Fatality. - Another accident at a hairdressing establishment which evoked even greater public attention was the "dry shampoo" case, a sad occurrence which has, we trust, resulted in the abandonment of the use of carbon tetrachloride as a cleansing agent for the hair. The victim of the unfortunate event was Miss DALRYMPLE, who on July 12th at HARRODS' Stores submitted herself to the process of dry shampooing with a liquid containing carbon tetrachloride in considerable amount and having carbon bisulphide as another of its ingredients. During the process she collapsed and died suddenly in spite of the attendant's best efforts on her behalf, and at the subsequent inquest she was stated to have been a subject of status lymphaticus. The jury, after a prolonged hearing, brought in a verdict of "Accidental death accelerated by the fumes of tetrachloride of carbon," with a rider, "that HARRODS' Stores were not justified in employing an unskilled operator to perform this dangerous operation." In consequence of this inquiry, on August 25th the Director of Public Prosecutions opened a prosecution for manslaughter against the manager of the hairdressing department of HARRODS' Stores and the assistant who gave the shampoo, in the course of which case Mr. A. J. PEPPER and Dr. W. H. WILLCOX gave important evidence as to the dangerous nature of the process in spite of the precautions observed by the defendants. The prosecution was not undertaken vindictively, but to establish publicly these important cautionary facts, and when at the close of the case for the prosecution Messrs. HARRODS announced that they had forbidden the use of the preparations of carbon tetrachloride in their establishment the charges were withdrawn by counsel for the prosecution with the approval of the presiding magistrate. It may be expected that as a result of this case the Privy Council will be advised by the Pharmaceutical Society to add carbon tetrachloride and similar substances to the Schedule A of the Poisons and Pharmacy Act. If any further proof of the desirability of this step be required it is to be found in the two communications based on experiments to determine the relative toxicity of pure and commercial carbon tetrachloride and of chloroform, which were contributed to our columns by Dr. A. D. WALLER and Dr. V. H. VELEY, in which it was shown conclusively that pure carbon tetrachloride has a toxicity double that of chloroform, and that the addition of 2 per cent. carbon bisulphide, as in the commercial article, increases the toxicity of the tetrachloride by 33 per cent. Dr. J. E. SANDILANDS also wrote to us to describe cases in which the use of the preparation had given rise to dangerous symptoms, and which he had observed. Any hairdresser using the preparation after the public exposure of its dangers will obviously lay himself open, in the event of a similar fatality, to a serious charge of manslaughter.

MISCELLANEOUS MATTERS.

The Working of the Midmives Act.—With reference to the remuneration of medical men summoned on the advice of midwives under the Midwives Act and the rules of the Central Midwives Board, and to the recommendations of the

Departmental Committee appointed by the Lord President of the Privy Council to consider the working of the Act, the Council of the London and Counties Medical Protection Society approved a recommendation of its Midwives Committee that the medical men in each union should meet and confer on the subject and should "agree as to what fee or fees they will accept, and then combine to insist on such fee or fees being paid (or guaranteed) by the guardians, and paid on the statement of the medical man that he is unable to obtain payment of his fee from the patient or her representatives.

The Notification of Births Act.—The proposed adoption of the Notification of Births Act by the borough council of Hackney was the occasion of a strongly worded protest signed by 53 medical men likely to be affected by it. The protest caused the adjournment of the proposal to adopt the Act and was directed against the compulsion upon medical practitioners to notify births (as they are already compelled to do in the case of deaths) without any fee. It was urged by the signatories, after reference to the notification of deaths without fee and the free services given in many cases of need by medical men, that " it is a strange return for such services to decree that because in the past we have done much and done it willingly—we shall in the future do more and do it compulsorily.'

A question was raised in the public health committee of the Fulham borough council as to how far medical practitioners likely to be affected had been informed of the adoption of the Notification of Births Act by that borough, it being obvious that a medical man not residing in a district where the Act is in force may attend a confinement within it. and through ignorance may commit a breach of the law by failing to give the prescribed notice.

The Poisons and Pharmacy Act, 1908.—This statute came into force on April 1st. It enlarges and alters the lists of poisons contained in Schedule A, Parts I. and II., of the Pharmacy Act, 1868, and takes out of the scope of that Act the sale of poisons to be used exclusively in agriculture and horticulture, or as sheep-dips or weed-killers, which are poisonous by containing arsenic, tobacco or its alkaloids. These are to be sold under licence from the local authority. The Act also amends Sections 15 and 16 of the Act of 1868. providing for the exhibition in the place where the business is carried on of the name and certificate of the qualification of any person carrying on the business of a pharmaceutical chemist or chemist and druggist, for himself or for others. It makes special provision in this connexion for the regulation of the business of a pharmaceutical chemist or chemist and druggist when carried on by a body corporate, or in Scotland by a firm or partnership. It gives power with regard to making by-laws for specified purposes connected with examinations to the Council of the Pharmaceutical Society, and makes special provision with regard to the sale of sulphuric acid, nitric acid, hydrochloric acid, and soluble salts of oxalic acid. Some, but not all, of the provisions of the Act apply to Ireland.

The Sanitary Oath. - An Act of Parliament has been passed and is in force providing for the administration of the oath in courts of law in the Scotch fashion. The Act does not order that the oath shall be, but that it "may" be, so administered unless the person about to take the oath voluntarily objects thereto.

APPLIED ANATOMY.

In briefly reviewing the progress of anatomy as reflected in our pages during the past year we propose to confine our résumé to those papers and observations which relate to the direct application of anatomy to the practice of medicine and surgery. This limitation of our anatomical survey is not

systematic lectures and articles on anatomy; they form the basis for further progress. We do so because of the limited space at our disposal and of the impossibility of doing justice to these morphological papers in so brief a review.

Head and Neck.

Progress in the application of anatomy to the service of the physician and surgeon is largely determined by the introduction of new methods of surgical procedure. The adoption of SCHLOSSER'S treatment for intractable neuralgia of the fifth cranial nerve, by injecting alcohol into the trunk of the affected branch, has led to a re-investigation of the position of the foramina by which the various branches leave the base of the skull. Dr. WILFRID HARRIS has described fully in our pages the various surface-markings he employs to reach the points of exit of the second and third divisions of that nerve, markings which he determined after a prolonged investigation on the cadaver. The application of radiography to the contents of the skull has yielded improved results; Dr. ROBERT KNOX has shown that not only can the pituitary body be registered on the photographic plate, but that its anterior part—the part enlarged in acromegaly—can be distinguished from the posterior part. Dr. G. RANKIN and Dr: R. O. Moon have given further details regarding the anatomical changes observed in acromegaly-a disease which throws light on the manner in which the shape and size of certain parts of the osseous system are determined. The attention now given to the diseases of the sphenoidal sinus has led to further observations on its position and relationships. Mr. W. S. SYME found in a series of 155 skulls that its orifice had an average distance of 2½ inches from the anterior nasal spine. Mr. SYDNEY R. SCOTT has made further investigations on the finer anatomy of the internal ear and shown how the pulsations of the internal carotid, acting through the labyrinth, may give rise to lateral nystagmus. The antrum of the middle ear has also received much attention, one of the chief additions to its anatomy being Mr. A. H. CHEATLE'S investigations into the varying nature of its mastoidal or outer wall. The cases of oxycephaly described by Dr. H. Morley Fletcher and by Dr. G. CARPENTER also deserve mention, not only on account of the optic atrophy which accompanies the condition, but of the light shed by these cases on the obscure problem of the manner in which the skull grows.

Observation has been directed to certain structures in the mouth and throat. Mr. RICKMAN GODLEE has published his observations on that peculiar form of exostosis found on the hard palate—the torus palatinus—a structure which escaped the notice, or at least the recording pen, of previous British surgeon-anatomists. Mr. R. C. Dun was able to show during the year a remarkable series of congenital malformations of the lip-two cases of median fissure of the upper lip and three of fistulæ of the lower lip. Professor A. Keith dealt with the malformations of the face and palate in demonstrations connected with the Museum of the Royal College of Surgeons of England. Mr. G. SECCOMBE HETT'S account of the comparative anatomy of the palatine tonsils fills up a blank in our knowledge of that structure, his work affording not only an explanation of the supratonsillar recess, but also a basis for the classification of enlarged tonsils. Mr. WILLIAM TAYLOR recorded a case of pharyngeal (improperly named cesophageal) pouch, but the cause and anatomy of these diverticula require further investigation.

The practice of nerve anastomosis has called attention to the relative positions of certain of the nerves of the head and neck, especially of the seventh, eleventh, and twelfth cranial nerves. A case of anastomosis between the eleventh and twelfth for the cure of lingual paralysis has been recorded by Mr. C. A. BALLANCE, and another between the seventh due to any lack of appreciation of the more theoretical and | and twelfth for facial paralysis by Mr. A. H. Tubby. The

erroneous hypothesis of MENDEL that the orbicular part of the facial nerve had its deep origin in the nucleus of the third nerve has been finally disproved by a case recorded by Dr. A. BRUCE and Dr. A. H. PIRIE.

Further cases have been described of cervical ribs causing atrophy and disturbance of sensation in the distribution of the first dorsal nerve to the arm and hand, a field of observation and treatment opened up by Mr. WILLIAM THORBURN and by Dr. Lewis Jones. In the case of a girl, aged 13 years, recorded by Dr. F. PARKES WEBER, it was found that a brother and sister also had cervical ribs, substantiating Dr. Theodore Thompson's observation on the hereditary nature of this abnormality.

In connexion with the anatomy of the head and neck mention must be made of the paper by Mr. F. G. PARSONS and Mr. P. W. G. SARGENT on the position and manner of termination of the thoracic duct in the neck, and of Mr. PARSONS'S published description of the age and sex changes in the hyoid bone of man.

The Thorax and Thuracic Organs.

As regards the heart very little has been added to our knowledge of its anatomy. Dr. G. A. Gibson and Dr. W. T. RITCHIE and Dr. W. LANGDON BROWN have recorded cases of Stokes-Adams disease in which the auriculo-ventricular bundle was more or less interrupted by fibrous atrophy of its muscle.. The neuro-muscular node at the junction of the superior vena cava and auricle, described two years ago by Professor KEITH and Dr. M. W. FLACK, has received considerable attention on the continent, but its functional nature has not been fully determined. Dr. A. Morison recorded a remarkable case in which the greater part of the right chambers of the heart had become completely replaced by sarcomatous tissue, and yet the heart continued to functionate. The same writer and also Dr. J. F. POYNTON and Mr. W. TROTTER have reported cases where thoracostomy has been performed to allow adherent hearts to execute their movements more freely. Observations by the electric cardiogram, further records of which have been published by Dr. A. D. WALLER, have again drawn attention to the fact that the base of the heart is a composite structure made up of the beginning and end of the cardiac tube. Professor KEITH in his Hunterian Lectures utilised the malformation of the heart as a means of analysing its component parts, showing that the infundibulum of the right ventricle of man corresponds with the fourth chamber or bulbus cordis of the heart of lower vertebrates—a chamber connected with the function of the heart as a respiratory pump. As regards the lungs, the thorax, and the mechanism of respiration, certain interesting if rather minor additions to our knowledge require mention. Dr. W. EWART has reviewed the various anatomical theories which have been offered to explain the clinical sign known as Grocca's triangle, but is unable to accept the explanation given by Professor Elliot Smith that it is due to the pleural fluid pushing the posterior mediastinal mesentery towards the sound side. Dr. R. H. SCANES SPICER has drawn attention to certain neglected movements of the trachea and larvnx which occur with the abdominal type of respiration, and regards these movements as predisposing certain parts to disease. Dr. J. S. DICKEY has again investigated the position of the cervical pleura, and finds that in the average individual it ascends an inch above the inner part of the clavicle and lies 14 to 11 inches deep to it. The nerve-supply of the pleura has been worked out by Dr. H. M. JOHNSTON from the intercostal and phrenic nerves. The same writer has also made a most valuable contribution to the segmental distribution of the spinal nerves on the dorsal aspect of the body. Two cases of congenital defects in the anterior wall of the thorax have been recorded by Professor A. M. PATERSON and Mr. T. H. C. BENIANS and Mr. H. E. JONES.

The Abdomen and Pelvis.

A considerable number of clinical records deal with the displacement of abdominal viscera. A displacement implies that the usual means of fixation have proved insufficient, but from a perusal of recent publications it is at once seen that there is a great difference of opinion amongst teachers and writers as to what the normal means are. There are, broadly speaking, two schools as regards this matter—one which regards the viscera as supported entirely by the contraction of the belly wall, and the other which regards the organs as fixed to the belly wall by mechanical means-ligaments, fascial bonds, and vessels. Practically all who have written on displacements of the abdominal viscera during the past year adopt the mechanical theory -Sir WILLIAM WATSON CHEYNE, (when dealing with moveable kidney and its treatment), Mr. E. W. HEY GROVES and Dr. I. WALKER HALL (the colon and its function), and Mr. ARBUTHNOT LANE. It is also so as regards the pelvic viscera. Dr. R. H. PARAMORE, however, has published several communications to show that the muscular pelvic diaphragm must be accounted of supreme importance in maintaining the uterus and vagina in position.

Closely related to the problem of fixation of the viscera is that relating to the regulation of the tonus of the muscles of the belly wall and the relationship between the nervesupply of the viscera and that of the belly wall. Professor C. S. SHERRINGTON dealt with these matters in his address to the British Medical Association at Belfast. Dr. JAMES MACKENZIE has again discussed the nature and substratum of visceral pain in his recent book on "Treatment." The use of X rays in studying the topography of the abdominal viscera has been further utilised. Dr. A. E. JORDAN published a series of observations on this subject. Mr. J. F. Dobson and Dr. J. KAY JAMIESON continued their experimental work on the lymphatics of the abdominal viscera, dealing with those of the colon in their communication published in the present year. A condition of the gall-bladder, recorded by Mr. Hugh LETT, deserves mention; the bladder was so freely surrounded by peritoneum that it became twisted on its own neck. Mr. W. BILLINGTON has added a case to the series recently described by Mr. Jonathan Hutchinson, jun., where the small intestine and colon, owing to the persistence of an embryonic arrangement of the mesentery, had formed a volvulus. The cases recorded by Mr. R. L. KNAGGS and by Mr. J. F. Dobson, of volvulus of the ileum in a hernial sac, illustrate the manner in which part of the mesentery becomes elongated when a loop of bowel descends within a hernial sac.

Dr. D. Berry Hart re-investigated the processes involved in the descent of the testicle and of the ovary, and applied Mendel's law to explain the atrophy of the male sexual parts in the female and of the female in the male. The abnormalities of the urachus, especially its cystic enlargement, has been elucidated by Mr. Alban H. G. Doran. Dr. E. J. EVATT has shown the manner in which the middle portion or lobe of the prostate is developed. Professor Paterson has written on the valves of Houston, and has shown that the transverse and constant fold which occurs at the reflexion of the peritoneum from the rectum to the vagina or bladder marks the junction of two physiological parts of that structure, the part below being for the mere passage of fæces but not serving normally as a fæcal receptaculum.

Spine and Limbs.

No better example of the manner in which clinical data can be utilised as a means of elucidating obscure anatomical problems could be cited than the recent papers on the sensory paths in the posterior columns of the spinal cord by Dr. Henry Head and Dr. H. T. Thompson. Dr.

THOMPSON has published during the current year his observations on the disturbances in the paths for sensory impulses in the posterior columns observed in patients suffering from tabes dorsalis. The further application of spinal anæsthesia has called increased attention to the influence of gravity on the cerebro-spinal fluid and the free communication that exists between the spinal and cerebral cisterns. Professor Rehn has shown that an injection of a solution of methylene blue in the spinal subarachnoid space of the horse appears within the ventricular system of the brain in from 10 to 25 minutes. By producing a temporary paralysis of nerves from the injection of a solution of eucaine and adrenalin Mr. WILFRID TROTTER and Mr. H. MORRISTON DAVIES have opened up a new method of determining the distribution of nerves by experiments on the living. Professor E. RUTHERFORD MORISON'S paper on laceration of the semilunar cartilages of the knee-joint has shown that the attachments of these cartilages are much stronger than are the cartilages themselves.

In the ARRIS and GALE lectures at the Royal College of Surgeons Professor ELLIOT SMITH showed how obscure problems relating to the functional nature of large areas of the human brain can be elucidated by the application of the methods of the comparative anatomist.

Changes in the Personnel connected with Anatomy.

The past year has seen almost a revolution in the occupancy of the leading chairs of anatomy. At Edinburgh Professor ARTHUR ROBINSON has succeeded the late Professor D. J. CUNNINGHAM, whose death was a real-almost irreparable -loss to British anatomy. Professor J. CLELAND has retired from the chair in Glasgow University and has been succeeded by Professor T. H. BRYCE. At Manchester Professor Elliot SMITH has succeeded Professor A. H. Young, who has unfortunately found it necessary to retire on account of ill-health. Professor PETER THOMPSON has succeeded to the chair vacated by Professor Robinson in Birmingham, while Dr. DAVID WATERSTON of Edinburgh has replaced Professor Thompson at King's College, London. The sudden and premature death of Professor ALEX. FRASER made a vacancy in the Schools of Surgery of the Royal College of Surgeons in Ireland, which has been filled by the appointment of Dr. A. CAMPBELL GEDDES of Edinburgh. Professor E. P. McLoughlin has been appointed to the new chair of anatomy in Dublin, while Professor D. P. FITZGERALD has succeeded to the chair of anatomy in Queen's College, Cork, formerly held by the President of the College, Dr. B. C. A. WINDLE.

THE NAVAL, MILITARY, AND INDIAN MEDICAL SERVICES.

THE ROYAL NAVAL MEDICAL SERVICE.

The Conditions of the Service.

In our yearly review at the end of 1908 we mentioned several particulars in which the medical service of the Royal Navy appeared to us to be in an unsatisfactory condition, the grievances of the officers falling under the two heads of the purely naval and the purely medical. We much regret that we are unable to chronicle any improvement at the end of another year. A committee was appointed, with Vice-Admiral Sir J. DURNFORD as chairman, to deal with these matters as long ago as last March, but up to the present no report has been issued. Mr. MCKENNA stated in the House of Commons in November that it was receiving earnest consideration, but he could not say whether it would be published. As this committee included (besides the naval Director-General) Sir ALFRED KEOGH and two eminent civilian surgeons (Sir W. W. CHEYNE and Mr. CHEATLE), it may be hoped that substantial improvement in the professional and service

conditions will result. From the correspondence that has appeared in the medical and service journals there seems to be still considerable dissatisfaction. The facts reported in connexion with a court-martial held on Fleet-Surgeon C. G. MATTHEW in September go far to explain this. It is true that the Fleet-Surgeon was acquitted, but the conduct of the naval officer in temporary command of the ship, as reported, is likely to act as a deterrent to intending candidates for naval medical commissions for some time to come. The immediate result has been that Fleet-Surgeon MATTHEW has resigned his commission and the service has lost an excellent officer.

Health of the Navy.

We reviewed the annual statistical report for 1908 in our issue of Nov. 20th. The health of the navy is satisfactory and improving. We have again to regret (as last year) the meagreness of this report, consisting, as it does, mainly of a collection of figures, without any attempt to extract their significance. An excellent account of original observations on heat-stroke by Staff-Surgeon O. Rees is the only matter of scientific interest.

THE ARMY MEDICAL SERVICE.

Scientific Work in the Royal Army Medical Corps.

No active service has fallen to the lot of our troops during the past year; the annals, therefore, of the medical corps have been uneventful on the purely military side. But "Peace hath her victories no less renowned than war," and the military members of our profession have a good record of scientific work accomplished in various lines of research. The Third Sleeping Sickness Commission of the Royal Society, directed by Colonel Sir DAVID BRUCE, is still in Uganda, where they have been working since October, 1908. From a communication to the Royal Society by BRUCE in May last, in which he reported that he had found Glossina palpalis infective after 16, 19, and 22 days, it appears that the trypanosome passes through a developmental cycle in the tsetse fly (as had been surmised). LEISHMAN has shown, in regard to tick fever, that natural infection occurs, not by the inoculation of unaltered spirochætes from the salivary glands, but through the agency of certain chromatin granules, either regurgitated from the intestine, or voided in the Malpighian secretion while the tick is gorging, so gaining access to the new host through the tick bite. Similar bodies may be the direct infecting agent in the case of G. palpalis. Captain H. ENSOR, D.S.O., attached to the Egyptian Army, has made some important investigations as to the areas of distribution of G. palpalis and G. morsitans in the Bahr-el-Ghazal province. Here sleeping sickness does not prevail, and apparently does not even exist, except in very rare instances; but Captain ENSOR anticipates that the disease may make its appearance by extension from the Congo Free State, and advises that arrangements should be made immediately (by clearing away trees and scrub from the banks of rivers and pools where G. palpalis abounds) to limit its spread. The subject is referred to further in the section on Tropical Diseases.

Records are accumulating to show the degree of protection afforded by antityphoid inoculation. Sir W. B. Leishman has summarised these up to June, 1908, in regard to a total strength of 12,083 men serving in India, South Africa Egypt, and the Mediterranean. The case-incidence of the 5473 inoculated was 3.8, and of the 6610 non-inoculated was 28.3 per 1000; but as no enteric cases at all occurred in five of the units (numbering in all 4204), if these are deducted, there occurred amongst the "exposed units" 6.6

In a communication to the Royal Society (Nov. 25th) the Commission state that the fly retains its infectivity up to 80 days, and possibly even for two years.

cases per 1000 in the inoculated and 39.5 per 1000 in the non-inoculated. But the first unit inoculated was treated with vaccine prepared by heating to 62°C.; the others have all been inoculated with vaccine heated only to 53°C. Taking this series of 6866 men "exposed" to infection, 3.7 cases per 1000 occurred in the inoculated and 32.8 in the non-inoculated.

The antityphoid vaccine has been employed therapeutically by Captain A. B. SMALLMAN in a series of 36 enteric cases at Quetta; there were three deaths, two occurring in fulminating cases about a week after admission. The treatment shows considerable promise for good. Very great attention has been paid during recent years in India to the combating of enteric fever by every means known; amongst others, by the most careful isolation of carrier cases. The ratio per 1000 of admissions has fallen from 20.6 in 1899 to 14.6 in 1908, and the deaths from 5.14 to 2.74. It is noteworthy that the admissions for dysentery have also fallen from 25.4 to 14.4, and the deaths from 0.65 to 0.42 per 1000 in the same period.

The importance of speedy recognition of B. typhosus in excretions is obvious. Captain H. B. FAWCUS, by combining Conradi's brilliant green and pieric acid medium with bile salt lactose agar, gets easy identification in 48 hours, typhosus colonies being transparent (together with paratyphoid, dysentery, and food poisoning bacilli), while coli colonies are thick and opaque.

The War Office Committee on Food, Training, and Clothing of the Soldier.

This Committee has issued three further reports. In the one dealing with marching exact and prolonged observations are recorded on pulse and temperature; and on the influence of variation in clothing, in load carried, and in the atmospheric conditions of air temperature, moisture, and wind on the pulse and temperature of the men under experiment; also on the effects of smoking and drinking (water and beer). The committee recommended that in warm weather men should march with the jacket and shirt open; that smoking in the ranks should be strongly discouraged; and that training in marching should be considered as of equal value with the technical "physical training." Many medical authorities have for years past advocated that the soldier should wear a loosefitting garment when at exercise, but hitherto the military idea of "smartness" has prevailed over the physiological and common sense recommendation that a man's chest should be free from constriction. The advocacy of practice in marching appears to be intended to counteract what is sometimes thought to be an excessive devotion to gymnastic exercises during the period of the soldier's training. The committee has also investigated the question of rations and made a large number of analyses of tinned meats, &c. It considers the present peace rations to be, on the whole, satisfactory, and proposes to make further investigations as to an active service ration. In a final report the committee expresses a favourable opinion on the new Mills-Burrowes pattern of equipment and of the soldier's clothing generally as at present provided.

Health of the Army.

The health of the army continues to show a progressive improvement, to which Mr. HALDANE drew attention in presenting the Army Estimates. This is observable in the home garrison, in India, and in the Colonies; but the improvement is most marked in the figures for India, where the death-rate has fallen to 8.38 and the invaliding to 8.84 per 1000 (1907).

Military Medical Organisation.

An important advance has been made by the issue of a scheme for the organisation of voluntary aid for sick and

wounded in the event of war occurring in this country. The Territorial county associations are brought into touch with voluntary aid societies through the medium of the British Red Cross Society, which will be considerably developed. This scheme was described in The Lancer of Oct. 9th. A commencement has also been made in the extension of military medical knowledge by the formation of the Officers' Training Corps, Medical Branch, which is distinct from the Territorial Force, but is intended to coöperate with it. The Universities of Edinburgh, Cambridge, Oxford, and London possess medical units in this corps. We note that the Army Medical Reserve (established 1888) was abolished by War Office Order of Nov. 27th, 1908.

As to military medical organisation generally there has undoubtedly been great progress. Sir John French, Inspector-General of the Forces, has reported that the training in camp of the Royal Army Medical Corps (both Regulars and Territorials) has been most valuable; actual training in field hospital and sanitary duties has been given, and the men have learned in practice the duties they would have to perform on active service. Strange as it may seem, this had never been done in the medical department until the last year or so; both officers and men were supposed apparently to be able to do their work under war conditions by the light of nature without previous instruction or training. The general commanding 2nd London Division, Territorials, organised a tour for the medical officers, a medical "staff ride," in which military and medical conditions were discussed on the spot with great advantage. It is a distinct sign of progress that the Army Council has intimated to general officers commanding that last year's training of the Royal Army Medical Corps (Territorial) reflected great credit on all concerned. A staff ride for medical officers was organised in Malta at the end of last year; "all officers gained valuable experience from the work done on the tour, especially from the discussion regarding the measures which should be adopted to meet some of the more critical situations." These staff rides and field trainings make for efficiency and are to be cordially welcomed. It may be noted that all the training of the Territorial Force is in the hands of organisations provided by the War Office, the Territorial thus having a great advantage over the Volunteer and Militiaman.

We may repeat here what has been recently said by Field-Marshal Sir Evelun Wood: "I am convinced, from my experience of 30 years as a general, that the army doctors should be regarded not merely as healers of the sick and wounded, but as trusted staff-officers to advise their chiefs how to guard the troops against the originating and spreading of disease, and thus maintain the number of effectives in a campaign. This will result not only in the increasing of fire effect, but will raise immensely the fighting value of the troops, and will incidentally enable us to reduce the costly and cumbersome hospital establishments and transport."

Army Medical College and Hospital.

At the Royal Army Medical College Major W. S. HARRISON has been appointed to succeed Lieutenant-Colonel R. J. S. SIMPSON, C.M.G., as professor of medicine; and Captain J. C. KENNEDY has succeeded Major HARRISON as assistant professor of pathology. At the presentation of prizes in July Sir Frederick Treves compared the position of the military medical officer with that of the profession in general to the advantage of the former, not only financially but in other ways as well; he also said that "the army medical officer has a greater prospect of attaining distinction in science than has the civilian practitioner."

The Army Council has decided that one candidate may be nominated for a commission in the Royal Army Medical Corps each half year by the Dominion of Canada, thus bringing the medical service into line with the combatant ranks in relation to our kinsmen in Greater Britain.

It is worthy of notice that the military hospital for London, which bears the name of Queen Alexandra's Military Hospital, Millbank, was honoured by a visit from Their Majesties the King and Queen on June 24th, when the new chapel, erected at the expense of an anonymous donor, was dedicated by Bishop Taylor Smith, Chaplain-General to the Forces. Lieutenant-Colonel W. B. Leishman was knighted on this occasion, and Colonel C. E. Harrison and Colonel D. Wardrop were appointed Commanders of the Royal Victorian Order. On July 9th H.R.H. Princess Christian graciously opened a new Military Families' Hospital at Shornecliffe, now called the "Helena Hospital."

The Director-General.

Sir Alfred Keogh retires on Jan. 1st, 1910, on completion of five years' service as Director-General, and will be succeeded by Surgeon-General W. L. Gubbins, C.B., M.V.O., who has had considerable previous personal experience at the War Office as Assistant and Deputy Director-General; and has also recently been Principal Medical Officer in India, a post of almost equal importance with that of the chief of the medical service at home. Sir Alfred Keogh is a difficult man to follow, but the service is now in a satisfactory position, and a continuance of existing policy would, we believe, meet with general approval. The work which Sir Alfred Keogh has accomplished in bringing the medical service of the army to its present state of efficiency, prosperity, and content deserves the fullest recognition.

Miscellaneous.

The United Services Medical Society has held regular and well-attended monthly meetings, at which matters of interest to the medical, naval, and military professions have been discussed. These meetings afford a common ground where civilians and service men may meet to their mutual profit. A great variety of subjects has been dealt with, ranging from purely scientific matters of laboratory research to clinical exhibits and practical points in Territorial recruiting. The Journal of the Royal Army Medical Corps maintains a high level of scientific interest; a glance through its contents shows the exceedingly wide scope of the duties, interests, and opportunities of the service members of our profession.

THE INDIAN MEDICAL SERVICE. New Proposals of the Scoretary of State.

The admitted need for an increase in the personnel, has been definitely acknowledged by the Secretary of State, who has decided that it is to be met, not by an increase on the civil side of the existing Indian Medical Service, but by gradually extending the employment of civil medical practitioners recruited in India. We ventured to consider this decision as of doubtful wisdom and even of doubtful expediency (THE LANCET, May 29th, p. 1537). One reason (though not by any means the only one) for arriving at this conclusion was afforded by a conviction that the Indian Medical Service would suffer in prestige and therefore in efficiency. The competition for commissions has already fallen below that for commissions in the Royal Army Medical Corps, quite reversing the rule that formerly obtained. That the proposal should be welcomed by the educated natives of India is only natural. At a meeting of medical men held in Bombay in September a memorial was adopted, to be forwarded to the Secretary of State, praying (inter alia) that the Indian Medical Service should be made a purely military service and that civil appointments be thrown open "to proved merit and ability wherever found, and that the sons of the soil should have an equal chance with their more fortunate brothers of the I.M.S." It was claimed that a saving of more than 25 lakhs of rupees would be effected.

There seems to be a general feeling, from correspondence. that has appeared in the medical press, that the Indian service does not now offer such pecuniary attractions as formerly; and if, in any new scheme, the higher professional and administrative appointments are to be taken away or diminished, that there will be a difficulty in filling even a restricted cadre. As recommended by "Furlough" in our issue of August 7th, the Government had better devote attention (1) to encouraging private practitioners, and (2) to the crying need for a properly organised native sanitary service. Between the two all the surplusage of Indiantrained graduates may be for many a year to come usefully absorbed.

An old-standing grievance was endorsed by the Naval and Military Committee of the General Medical Council last year. It considered that the restrictions placed upon officers of the Indian Medical Service, regarding fees paid to them by natives of India, were oppressive and unnecessary, interfered with the rights of private practice, and lowered its prestige disastrously, and a communication to this effect was addressed to the Secretary of State in November, 1908.

The Director-General, I.M.S.

Lieutenant-Colonel C. P. LUKIS has been selected to succeed Sir GERALD BOMFORD as Director-General. He is a most popular officer of the highest professional attainments, who has lately been principal of the Medical College in Calcutta; and as to his personal fitness there is no question. But he has been promoted over the heads of all the surgeongenerals and colonels—that is, over all the administrative officers in the country. It is not unnatural that there should be a feeling that the chief administrative officer should have had, at any rate, some experience in administration, both military and civil.

Scientific Work.

The Kasauli Pasteur Institute, under the direction of Lieutenant-Colonel D. SEMPLE, continues to do good work. During 1908 there were treated 1349 cases of bites by rabid animals, with only 0.44 per cent. of failures, the lowest since its foundation in 1900. The system adopted is Professor Hoyges's modification of the Pasteur method, as worked out by Captain W. F. HARVEY and Captain A. D. McKendrick. It is simple, accurate, and accompanied with fewer ill-effects than the older procedure. In the preparation of antityphoid vaccine Lieutenant-Colonel SEMPLE and Captain H. S. MATSON recommend sterilisation with pure carbolic acid, 0.5 per cent., without any heating. Both civil and military officers of the Indian Medical Service can now go through a month's course at the Kasauli Institute in clinical bacteriology and technique; they receive full pay and travelling allowance.

In a report on enteric fever in India by Lieutenant-Colonel SEMPLE and Major E. GREIG the authors sum up to the effect that chronic carriers are the chief agents in the spread of the disease; they consider that a trained body of men nurses is required, and that bacteriological examinations should be made of the excreta of all persons—European and native—engaged in the preparation and distribution of articles of food and drink. The epithets herculean and gigantic are quite inadequate to express the magnitude of this task.

Major A. E. BERRY and Captain R. C. MACWATTERS, I.M.S., have reported in the *Indian Medical Gazette* for February, 1909, the results of antiseptic surgery in the Zakka Khel Frontier Expedition. Out of 96 wound cases in the 10th Native Field Hospital only 10 suppurated; of these 10, one communicated with the mouth, and in two the bullet had been left in the wound; five were comminuted fractures. They note that no wounds that had been disinfected under an anæsthetic (soilicet, thoroughly) suppurated, and they regret

that they did not more frequently use chloroform, so as to scrub more thoroughly.

Personal.

The honour of K.C.I.E. has been conferred on Surgeon-General Bomford, the late Director-General I.M.S., and that of C.I.E. on Lieutenant-Colonel J. T. W. LESLIE, Sanitary Commissioner with the Government of India, and on Major W. H. Orr for famine work. Surgeon-General L. D. Spencer, has been made K.C.B. Amongst the losses by death we especially regret to note those of Sir George King, K.C.I.E., F.R.S., the eminent botanist and superintendent of the Calcutta Botanical Gardens, who was instrumental in establishing cinchona cultivation at Darjiling; and of Surgeon-General J. S. Tuson, the inventor of the well-known belmet.

A medal for Pathology has been founded by officers of the Indian Medical Service in memory of the late Sir JOSEPH FAYRER, to be competed for at the Royal Army Medical College by probationers for the Indian Medical Service,—an excellent way of keeping green the memory of one who was always an enthusiastic supporter of the old Army Medical School at Netley and a devoted friend to both Army and Indian Medical Services.

Bombay Medical Congress.

A long time has elapsed since the first Indian Medical Congress, due chiefly to the initiative, and held under the presidency, of Surgeon-General R. HARVEY at Calcutta in 1894. A well-attended and successful Medical Congress was held at Bombay in February, under the presidency of the Governor, His Excellency Sir GEORGE CLARKE, who read an address on Medical Progress in that Presidency. The Congress was divided into six sections, three being concerned with tropical medicine, and one each devoted to sanitation and surgery, while the exhibition formed the sixth. The address by Professor RONALD ROSS in Section II. was a stirring appeal to action against malaria. There has been enough of inquiry, he said; it is now time to act; begin with those measures which can be adopted immediately -that is (speaking generally) those that cost least. Major Ross considers that all prophylactic systems are good: for large towns (as a rule) mosquito reduction by drainage, for rural areas prophylactic quinine administration, in severe malaria both methods should be carried out. The Italian system of mosquito proof huts or houses was not given equal commendation. Major S. P. JAMES and Captain S. R. CHRISTOPHERS in their address considered that a change of opinion had taken place in regard to mosquito reduction by drainage; whereas it used to be thought easy, that is not the case now; and on the whole they were against it as a practical measure. Major C. Donovan spoke on kala-azar. Major G. LAMB believed that plague is entirely dependent on rats, the infection being conveyed by the flea; insanitary conditions he thought to be of no account except as favouring rats. Plague is often conveyed from place to place by rat fleas imported in the baggage or on the persons of travellers, who may themselves escape infection. Lieutenant-Colonel A. BUCHANAN brought forward additional facts as to cats as plague preventers. Dr. W. L. BRADDON contributed an excellent paper on beri-beri, proving its dependence on a diet composed of rice, and rice of a particular kind-namely, that which is decorticated and

Conference on Malaria.

The Conference on Malaria that was convened at Simla in October, and reported in our issues of Nov. 13th and 20th, though on a much smaller scale, is likely to have a farreaching effect. The presence of the Viceroy himself, who gave an opening address, and of the Lieutenant-Governor of the Punjab, who said that "to cope adequately with this

curse of the country had been his chief endeavour since he assumed charge of the l'unjab Government," gives assurance that the effectual support of the highest authoritywhich, of course, means provision of the necessary funds -will be forthcoming for well-considered measures of prevention. Lieutenant-Colonel LESLIE, Sanitary Commissioner, expressed most clearly some of the difficulties of the problem to be faced. He denied the truth of the statement that had been made that mosquito destruction had been neglected, but pointed out the difficulties that had been met with-much greater in many places in India than at Ismailia and other fever centres where such brilliant results had been previously obtained. He referred to the great success of the routine quinine administration (10 grains to each prisoner on admission and 15 grains weekly afterwards) by Colonel G. F. W. BRAIDE in the Punjab jails. The admission-rate for fever had been only 173.5 per 1000 (including pyrexia of uncertain origin), the lowest on record; and the malarial death-rate the lowest with one exception; this success was obtained in 1908, an extraordinarily bad year for fever. It is proposed that a malaria committee shall be formed for each province, a meeting of delegates to take place each year at Simla, and scientific observers to be constantly at work. As evidence of the scientific appreciation of Professor Ross's past work on malaria, we may mention that the Royal Society has recently presented to him one of its gold medals. In November it was stated in the House of Commons that a special permanent grant of £200,000 a year had been made by the Government of India to provincial governments for additional expenditure on sanitary measures. Such admirable promptitude in providing the sinews of war is a proof of entire change in Indian administrative methods in sanitary matters as compared with former days.

PHARMACY.

Pharmaceutical Politics: the Poisons and Pharmacy Act.

The practice of pharmacy during the past year has been attended by the new conditions imposed by the Poisons and Pharmacy Act, which came into force on April 1st, and the events which have arisen in consequence of the operation of this Act have overshadowed incidents which in other years might have attracted more interest. The progress of pharmacy proper, by which is meant the scientific side of the calling, has been slow, which is perhaps not unnatural, since the attention of pharmacists has been mainly absorbed by what it is usual to classify under the vague but comprehensive term of "pharmaceutical politics." One of the main provisions of the new Act was that which gave to all registered individuals, and to them alone, the sole right to use the title of "pharmacist," in order that there might be some means of distinguishing them from joint stock companies carrying on the same class of business. The same reservation was not made applicable to the sign "pharmacy," but it was thought that this was provided for by the Pharmacy Act of 1852. In order to test the validity of this view the Pharmaceutical Society instituted proceedings against an unqualified person whose shop bore this sign. In the county court the society was successful, but on appeal the decision was reversed by a Divisional Court. In the county court the society relied on the Barnes r. Brown decision, by which the words "specially qualified" in Section 3 of the Dentists Act, 1878, were interpreted as implying "special qualifications to practise dentistry." Before the appeal was reached this decision was overruled by the judgment of the Court of Appeal in the dental partnerships case (Bellerby v. Heyworth), in which case it was held by the Master of the Rolls that the section was directed to the personal description of the workman as distinguished from the description of the work

which the man does. The result of the decision of the Divisional Court in the Pharmaceutical Society's case was to show that the sign "pharmacy" was one which any could use, and this at once diminished the value of the word "pharmacist" as a professional title.

Another object of the Act was to facilitate the sale of horticultural and agricultural poisons containing arsenic and nicotine, by empowering local authorities to grant licences to seedsmen, florists, and others in districts where the reasonable requirements of the public were not provided for. The local authorities in many districts have administered this provision in a spirit wholly contrary to the intentions of the Act, and have granted licences in places where the supply of chemists' shops in which these articles are sold is more than adequate to meet the needs of farmers and gardeners. It appears, very unfortunately, that so long as the local authorities comply with certain technical formalities there is nothing to prevent them from multiplying indefinitely the sources from which these potent substances may be obtained. The Act also invested the Council of the Pharmaceutical Society with powers to make by-laws to require candidates for the qualifying examination to produce evidence of having pursued a specified course of study, and this question of establishing a curriculum has been referred to a committee of the Board of Examiners who, it is expected, will present a report early in the new year. The society was also empowered to make by-laws to accept for registration in lieu of examination the assistants' certificates of the Apothecaries' Society, but the President has publicly stated that any person who desires to become registered as a pharmacist will have to produce evidence of having attained to such a standard of education as is reflected in the society's examination. provisions requiring the exhibition in every chemist's shop of the certificate of the registered person in charge, and for the registration of the superintendent of that part of the business of any joint stock company relating to the sale of poisons, have been well observed, and there can be little doubt that the sale of poisons is under more effective control than was formerly the case.

Before passing from the consideration of the administrative functions of the Pharmaceutical Society, it should be mentioned that it is intended in future that pharmacists trading under names other than their own shall strictly observe the provisions of Section XVII. of the Pharmacy Act, 1868, which requires that all poisons sold by retail shall be labelled with the name and address of the seller, the "seller" being the person on whose behalf the sale is made —that is to say, the person who owns the shop. The society holds the view that the "trade name" is not sufficient to comply with the law, and this view has been upheld by the magistrate at Old-street police court. A trade name may still be used, but on poison labels the actual name of the owner of the shop must also appear. Compliance with this provision will obviously work to the advantage of pharmacists as distinguished from companies, and will make for better administration of the law. The inclusion of sulphonal in the new Poison Schedule has apparently had the effect of enlarging the sale of non-scheduled soporifics of a like nature in proportion to the diminished demand of the scheduled substance. This suggests a further extension of the list of poisons.

The Parliamentary Fund.

It will be observed that the statutory conditions governing the practice of pharmacy are far from satisfactory, and very tardily pharmacists have come to the conclusion that it would be to their interests to secure direct representation in Parliament. Accordingly, some months ago a Parliamentary fund was started and its committee chose as the pharmacists' representative the candidate who has now been selected to

contest the Stepney Division in the Liberal interest. Should' the fund be sufficiently well supported it is intended to select a second candidate, and in order to avoid any difficulties which party politics might occasion the second candidate will be a Conservative. One important matter which would necessarily engage the attention of a pharmaceutical Member of Parliament is the question of dispensing in public institutions. Considerable dissatisfaction has been aroused by the attitude of the Home Secretary, who gave a negative reply to a question asked in the House of Commons as to whether he would consider the advisability of introducing legislation to provide that the dispensing of poisons in public institutions should be subject to the same restriction as their sale in chemists' shops and placed under the control of registered pharmacists.

Secret Remedies.

The question of the sale of secret remedies has again been engaging the attention of pharmacists, to many of whom this traffic is revolting. The number of chemists' shops in Great Britain is between 9000 and 10,000, but the number of traders licensed at the present time to sell so-called "patent" medicines is over 40,000. The majority of pharmacists cordially support Captain CRAIG in his endeavour to persuade the Government to appoint a Select Committee to consider the advisability of requiring makers of proprietary medicines to disclose the composition of their preparations.

Scientific Progress.

For the advancement of pharmacy, in its scientific aspect, it is customary to rely, to a considerable extent, upon the British Pharmaceutical Conference, and upon a few independent workers who usually place their results before the evening meetings of the Pharmaceutical Society which are held during the winter in London and Edinburgh. The papers contributed at the conference meeting this year included several of practical value, brief abstracts of which have already appeared in THE LANCET. In passing, attention may be drawn to a paper inspired by the proposed increase in the duty on spirit which has proved a costly proposal topharmacists, since this paper suggested cases where the proportion of alcohol might with advantage be reduced and also where glycerine and acetic acid might replace it without disadvantage. The papers communicated to the Pharmaceutical Society have been of average importance and in many instances of especial interest to those who pursue their calling in its higher branches. The pharmaceutical papers read at the International Congress of Applied Chemistry held in London in May were not, taken as a whole, of such a high standard as was expected, but a few of them will undoubtedly serve a very useful purpose, more especially those relating to the question of international standards. The Hanbury medal was this year presented to Dr. TSCHIRCH, who succeeded to FLÜCKIGER'S chair in the University of Berne, and with him produced one of the best known standard works on pharmacognosy. The Committee of Reference in Pharmacy to the Pharmacopæia Committee of the General Medical Council presented a report early in the year which embodied some important recommendations. No doubt the pharmacy of the next British Pharmacopœia. will bear evidence that the experienced pharmacists who form the committee have expended a considerable amount of time and brought mature consideration to bear upon the work entrusted to them.

CHEMISTRY.

The year has witnessed very few brilliant practical announcements from the chemist, and on the whole it would seem that theoretical considerations have received the largest share of attention. What has been called "the new chemistry" has clearly come to stay, and the old school of

thought which scoffs at the theory of ions is receiving warning to set its house in order.

Radio-activity.

The study of radium and of radio-activity in general is calculated to receive considerable impetus from the formation of an institution (the Radium Institute), in which the physiological and therapeutical effects of radium salts and their emanations can be advantageously observed. Also it was announced during the year that radium is to be both quarried and recovered from its ore in England, and a process is soon to be begun at works in London, which, owing to the investigations of Sir WILLIAM RAMSAY, succeeds in recovering radium from pitchblende in a comparatively short time. Meanwhile, chemists and physicists are working hard on the problem of the nature of radium emanations, and medical men are devoting their attention to such questions as the way in which these emanations act and their effect upon tissue. An oxidising property is one hypothesis which receives support from the fact that the B-rays, at any rate when they act upon distilled water, produce hydrogen peroxide. A similar effect has been shown to be produced when the ultra-violet rays act upon water. One of the most promising fields of study is that of the ultra-violet rays; and since these rays are capable of producing ozone, oxygen, hydrogen peroxide, and act as powerful germicides, besides taking a share in the assimilative processes of plant life, there seems to be little doubt that the human race owes much to them.

Tons.

There are not a few scientific men who are opposed to the theory of ions, but unsatisfactory as a theory may be, in the light of every consideration it is convenient to retain it when facts which fit it so well are not wanting. We have all along maintained that the chemist's and physicist's view of electrolytic dissociation, or the resolution of a salt into its negative and positive ions, would mean something fresh in therapeutics. Events have justified this prediction. The application of the theory of ions in medicine is now an established fact. The chemical actions, and consequently the toxic. antiseptic, and therapeutic actions of electrolytic substances, are almost exclusively the actions of their ions, and the grouping of the ions determines definite physiological action. Take, for example, the action of the new organo-arsenic and organomercury compounds. Arsenic and mercury are, relatively speaking, non-toxic in the form of complex salts such as the cacodylates, atoxyl, and so forth, because the arsenic and mercury exist in a complex ion instead of, as in the case of the arsenites or mercurials, in a simple ion in which the identity of the poisonous metal is not lost. Medical ionisation, kataphoresis, or iontophoresis are the terms used to imply the introduction of ions of different sorts into the tissues of the human body, the body itself being a reservoir of saline solution containing many ions. Treatment by ions or by electrolytic dissociation means in reality a steering of an active therapeutic group to the area in which the application is required. As an illustration-if we want to silver plate copper we make the copper the negative pole in a solution of silver salt, and on passing a current of electricity through the solution the positively charged silver ions attach themselves to the copper. The application of the ionic theory in several branches of medical practice has been favourably reported on during the year.

The Ether.

The presidential address at the British Association for the Advancement of Science, which was delivered at Winnipeg by Sir J. J. THOMSON, referred chiefly to facts about the ether, that mysterious medium of all light vibrations. The importance of the ether to all lies in its function as a transmitter of energy. If it were a resistance instead of a conducting

medium it is easy to prove that life would cease. Ether must possess an interest for medical men, since without an acknowledgement of its existence we are left little chance of arriving at an intelligible explanation of the nature of the action of so many kinds of rays in the treatment of disease.

Transmutation.

Sir WILLIAM RAMSAY has continued his work upon the effect of radium energy upon the elements, but so far no startling progress has been reported. An experiment was recorded, however, during the year, from which the author concluded that gold had been converted into copper by merely exposing the former metal in a pure state to the influence of high potential discharge. We have not seen any further reference to the experiment nor to any other experiments which could be quoted as confirming the alleged initial result.

Food from the Air.

CAVENDISH little thought that his classic experiment in 1781, in which he produced small quantities of nitric acid from the nitrogen of the air in a eudiometer, was going to possess anything more than a theoretical importance. Yet such has been the progress made in the direction of utilising natural forces that at the present day hundreds of tons of nitrate available for the fertilisation of the soil are being manufactured from the nitrogen of the air by the agency of water power and electric potential. The probability is that the output of air saltpetre will soon amount to 100,000 tons per annum. The world need therefore have no fears as to the source of its supply of nitrogen available for the needs of plant and animal life.

Silicon as a Substitute for Carbon.

Organic chemistry has been defined as the chemistry of carbon compounds, but Professor EMERSON REYNOLDS has shown that silicon may enter into the composition of protoplasm in the place of carbon. Under suitable conditions, he points out, a plant or an animal organism may be able to construct from silicon compounds, ultimately derived from the soil, something akin to silicon protoplasm for use in its structures. In marine life, at any rate, silica appears to be used in cell production. The beautiful spicules found in the sponge appear to be definite growth from cell protoplasm. The sponge would seem to appropriate the silica of the sea and to use it in cell production, evolving "the beautiful and minute siliceous spicules which are so abundant throughout the structure of many sponges." It is well known that silicon can be made to replace carbon in a number of definite chemical compounds.

Our review of the salient features of chemical researches during the year is necessarily brief, but enough has been quoted to show how valuable is the work of the chemist in throwing some light on life's many problems.

CONTRIBUTIONS FROM THE LANCET LABORATORY.

The principal work in THE LANCET Laboratory this year has been the investigation into the question of the Standardisation of Disinfectants. The result of this inquiry has been published recently in THE LANCET (Nov. 13th, 20th, 27th), and our readers will readily see from the report that it entailed a considerable amount of laboratory work. We believe that the report sets out a fair statement of the composition of the disinfectants which are commonly sold to the public, and it would appear that reliance is placed now chiefly upon the coal-tar preparations, which contain phenols or phenoloids of ascertained germicidal power. While we know that this report, based upon a considerable amount of chemical and bacteriological work, adds considerably to our information upon the variations both as regards chemical constituents and bactericidal power of commercial disinfectants, there are opened up further questions, the

principal of which is the actual value of these disinfectants under the exacting conditions of practice. As yet no reliable estimate has been prepared by anyone of the value of disinfectants when employed under practical conditions. The order of merit obtained in bacteriological experiments may be modified when we come to practical considerations, but that is an important branch of the question which has as vet not received definite attention. It is quite clear from our report that the present position of the sale of disinfectants is unsatisfactory, for it is shown that the actual percentage of germicidal constituents varies enormously, whilst the price for a definite volume of the coal-tar fluids is for all practical purposes uniform, it being remembered that all of them become cheaper if bought in bulk. We do not claim to have reached a final settlement of the many questions involved, but we submit that we have cleared the issues.

In the early part of the year we received from our correspondent in Peking a number of preparations which were being sold in China as anti-opium remedies. In the majority of cases these "opium cures" took the form of pills, and of 12 samples examined it was shown that not less than 75 per cent. of them contained a marked amount of morphia. The wickedness of this business is evident.

An interesting observation was made in THE LANCET of Jan. 2nd, when an analysis of the snow which fell heavily in London in the week previously was made in THE LANCET Laboratory. The result showed a remarkable amount of ammonia and sulphuric acid in the snow, which proved that these contaminations were due to the domestic fire. It was calculated that the fall was so heavy that hundreds of tons of sulphuric acid and ammonia must have been brought to earth.

In an inquiry made by our Special Commissioner into the filthiness of flock used for bedding several samples were referred to the laboratory for examination. The results appeared in The Lancet of Jan. 23rd. They showed the offensiveness of the untreated flock and its inoffensive character when washed and sterilised.

In THE LANCET of March 6th an interesting comparison based on analytical results from the laboratory appeared between the composition of a weekday and a Sunday fall of snow. The differences were quite remarkable, the Sunday snow showing roughly one-fifth less of the impurities present in the week-day snow, the differences being due chiefly to sulphur compounds and tarry products.

The report of the Royal Commission on whisky and other potable spirits appeared in August and we commented upon it in a leading article in THE LANCET of August 14th. The question of the desirability of exercising further control over the sale of potable spirits had, we believe, its origin in the practical interest we have taken in the subject. We confess that the report was disappointing, and should but little advance upon the conclusions arrived at by a Select Committee which was appointed in 1890. The Commissioners did not regard it of importance to differentiate pot-still from patent-still whisky. They concluded, moreover, that age made no difference to the suitability of the spirit for human consumption. Practical experience, we urged, was against such a conclusion. They further gave their opinion that as long as brandy was made from wine it did not matter whether it was produced in the pot-still or patent-still. We disagreed again. We welcomed, however, the recommendation that a committee should be formed of skilled persons under Governmental authority who might assist in mitigating some of the difficulties of the subject by advising on technical questions which affect both the administration of the Sale of Food and Drugs Act by local authorities and the practice of public analysts. We are not aware that such a committee has been formed.

During the year the work of special investigations in THE LANCET Laboratory involved the making of 238 analytical determinations, whilst the figures of analysis in our columns of Analytical Records amounted to 203, making a total number of analytical estimations of 441.

As is usually the case, a number of quack remedies has been submitted to the laboratory for examination, and the results have been communicated to our correspondents.

THE GENERAL MEDICAL COUNCIL.

The work of the General Council of Medical Education and Registration has been regularly chronicled in our columns throughout the year. Both the spring and autumn debates were characterised by the strict attention to business which we now expect with so much confidence that anything like a disorderly discussion, beginning on a point not germane to the topic and ending in no decision in particular, would come as a great surprise. Yet such debates have occurred in the history of the Council.

The personnel of the Council has been altered during the year in several ways. The death of Dr. J. LINDSAY STEVEN, cut off in his prime, deprived the Council of one of its most clear-headed and well-informed authorities on medical education, while the retirement through ill-health of Dr. P. H. PYE-SMITH and Dr. ALFRED H. Young left blanks which, though admirably filled, can still be felt. It has now been definitely decided to add to the General Medical Council an additional Direct Representative of the medical profession for England and Wales, and the new member will bring the number of the Council up to 35. We have always considered it essential that the medical profession as a whole should have a voice in the affairs of the General Medical Council, especially because the penal authority of the Council is at the same time so delicate in its work and so tremendous in its issues. In a sense, of course, every practitioner is represented on the Council by the representative of his educational body, of his university, or of his corporation, but there has always been a need for voices in the discussions which owe no allegiance to anyone save the constituency at large. We welcome the addition to the small group of Direct Representatives.

The Council has been during the year able to play an important part in medical politics, and one no doubt which will be felt in the actual constructive legislation of the future. The Council has made representations to the Government through the Privy Council with regard to the appointment of a Royal Commission to inquire into the full effects produced by the unrestricted practice of medicine and surgery by unqualified persons, and the Lord President of the Privy Council is now making preliminary inquiries on the subject through the Local Government Board. The Council has also presented its views to the Privy Council on the question of a Bill for the Registration of Nurses, and Sir DONALD MACALISTER has been able to say that there are grounds for believing that the executive committee of the Council will be entrusted, in any legislation which may occur, with some such supervising authority as is now vested with regard to the Midwives Act in the English Branch Council. In respect to the very difficult question of legislation on the administration of anæsthetics the Council arrived, following the recommendations of its Anæsthetics Committee, at some sagacious resolutions which, while leaving unchanged the present position of the qualified dentist, provide in the public interest that the administration of anæsthetics should be restricted by law to practitioners on the Medical Register, with the additional qualification that in ordinary circumstances the single-handed induction of unconsciousness during any medical, surgical, or dental operation was held to be inexpedient. It is certain that the Departmental Committee of the Home Office, which has the whole question

of anæsthetics under its consideration, will attach the first importance to the views of the Council.

The other great matter debated by the Council was the report of the Education Committee on the distribution or the medical student's time between the several parts of the curriculum. This report has long been before the Council, and the interesting debates which it, and the suggestions arising out of it, have produced have been regularly reported in our columns. The Council has arrived at the conclusion that the regulations apportioning the student's time between the preliminary and final subjects should be so framed as to ensure that the study of the final group of subjects should extend for not less than two years after passing the examination in anatomy and physiology. This is, to a certain extent, the adoption of what is known as the "block" system, and the objections to that system are as well known as its advantages are obvious. In the last of a series of special articles on Medical Education, which we publish this week (p. 1935), this particular question is touched upon, while the whole series testifies to the valuable labours of the Education Committee of the Council. Many questions with respect to the medical curriculum are still left open for discussion, and the increasing scope of medical education will inevitably add to these questions. Council, in accordance with its duty as the central educational authority of the profession, will continually have to debate the matter of the curriculum, but great order will be brought into these discussions by the definite position which it has now reached. For the Council the year has been a quiet but an eventful one.

THE BRITISH MEDICAL ASSOCIATION.

During the year the petition for a Royal Charter of Incorporation made by the British Medical Association has been under the consideration of the Privy Council, and although certain objections have been raised against its grant by other bodies, who consider that it infringes their privileges, we understand that the objection which was threatened from within the ranks of the Association at the end of last year has been dropped by mutual agreement. As usual, the great public event of the year in connexion with the Association was the annual meeting for scientific and social intercourse, and the success of the July gathering at Belfast has never been surpassed Not only were many of the papers read of an unusually high level, but the hospitality of the city and the excellence of the arrangements at Queen's College (now Queen's University), where the meetings were held, made the occasion extremely pleasant for the members and guests who attended. Unhappily, Mr. SIMEON SNELL, the President elected at last year's meeting at Sheffield, had died before the completion of his year of office. It fell upon Mr. SINCLAIR WHITE, his successor, to induct Sir WILLIAM WHITLA into the chair of the Association and to discharge Mr. SNELL's other duties, which he did to universal approval. Sir WILLIAM WHITLA delivered his official address to a very large audience, taking for his subject "The Belfast Medical School: A Survey of the State of Medical Education: Necessary Reforms, and the Queen's University of Belfast." The address in Medicine on "Progressive Medicine and the Outlook on Tuberculosis" was delivered by Dr. R. W. PHILIP; the address in Surgery on "Progress in Intestinal Surgery," by Mr. A. E. BARKER; and the address in Obstetrics on "The Present Position and the Future Developments of Obstetric Medicine," by Sir John W. Byers. All these addresses, besides the proceedings of certain sectional meetings connected with public health and tuberculosis, were attended by the Viceroy and Lady Aberdeen, and the official notice thus bestowed upon the meeting had its

social effect. The scientific work was done in 17 sections, of which that concerned with Hæmatology and Vaccine Therapy, under the presidency of Sir ALMROTH WRIGHT, made its first appearance on the programme. The speeches of Professor Bordet and Professor Calmette gave an added distinction to the debates of this section. The usual annual exhibition of foods, drugs, instruments, and books was held during the meeting, and was described in our columns, and a particularly interesting feature was an exhibition of old and valuable medical books and MSS. under the auspices of the Medical Library Association, a body having objects which were brought prominently forward by an address delivered by its president, Professor WILLIAM OSLER, on "The Medical Library as a Factor in Post-graduate Work." The meeting was brought to a close by the usual visits to places of interest in the neighbourhood. Contrary to custom, the place of meeting for the next year was not announced until after the Belfast gathering, but it has since been decided to meet in London in 1910 under the presidency of Mr. BUTLIN.

THE SIXTEENTH INTERNATIONAL MEDICAL CONGRESS.

The Sixteenth International Congress of Medicine met this year at Budapest from August 29th to Sept. 4th. The management of the Congress was excellent. The members, in spite of their great number, had no difficulty in finding their correspondence, their invitations, and the various books and documents that were distributed, and even in regard to lodgings there were no complaints. Over 4300 congressists assembled, including the 900 ladies who accompanied them. At some of the receptions there certainly was an unpleasant crush, and on one occasion the cloakroom arrangements broke down. On the other hand, at some of the receptions, notably that given in the name of the Hungarian Government by the Count and Countess APPONYI in the Park Club, the guests experienced no overcrowding and no difficulty even at the supper table. As for the opening ceremony and the reception at Court, the pageant on both occasions was remarkably brilliant. On several occasions, both at official and private gatherings, some very remarkable speeches were made, and prominent among these was the inaugural discourse delivered by His Imperial and Royal Highness the Archduke Joseph. Speaking words of welcome on behalf of the Emperor, the Archduke, in very emphatic language, proclaimed himself an advanced social reformer. He declared that every living being had "a right to happiness," and that to be at the service of humanity, to consecrate all the physical forces and intellectual faculties which GoD has given to the welfare of our fellow-being, constituted an ideal existence. It is because the medical profession was so largely devoted to the good of humanity that the Archduke was glad to welcome its representatives.

Though the Budapest Congress was much better organised than many of its predecessors, nevertheless a strong feeling has prevailed for many years that too much is left to local organisers and to chance. There is a lack of continuity in these congresses. The towns where they are held are apt to vie with each other in the endeavour to attract a record number of members. Yet it is quality rather than quantity that is needed, and the greater the number of members attending a congress the more difficult it is to organise their work in an effective manner or to receive them properly. In these circumstances, it was determined to bring about, not a constitutional reform, because the trouble rests in the fact that there is no constitution, but the substitution for a few unwritten traditions of a real and definite system of management. These congresses not only have had no constitution, but they have had no machinery wherewith to

make one. Certainly the presidents and secretaries of the national committees, the leaders of Government delegation, and the local executive committee managing the congress generally meet while the congress is sitting and form a sort of governing body. Though possessing no clearly defined function or authority, the international committee thus formed was the only body to which a proposition to draw up a constitution could be submitted. There were two such proposals. One emanated from Professor Calman Müller and the Budapest committee, the other from the British branch of the International Association of the Medical Press. The former was very brief and did not cover the whole ground; the latter was more complete and more carefully worked out. The former had the advantage of being printed and submitted to the national committees before the Congress met; the latter came in the form not so much of an amendment, but as an elaboration, and was only presented when the International Committee described above met at Budapest. This meeting was of such short duration that nothing approaching to a proper discussion could be held. The proposal emanating from Budapest was hastily adopted, together with some additions taken from the proposals of the British branch of the International Association of the Medical Press. The main result attained is that a Permanent International Commission for the Management of the International Congresses of Medicine is now created, and that these congresses are to meet every fourth instead of every third year. On this Commission the International Association of the Medical Press is to be represented by its President. The headquarters of the Permanent Commission are to be at The Hague, with the power, however, of meeting wherever and whenever convenient. The presidents and general secretaries of past congresses are to be ex-officio members, and one delegate elected by each national committee, with the press representative, are to form the Commission. As there are many things for them to organise and to do it is to be hoped that they will soon hold a meeting. There is much waste of energy, time, and money at these congresses, which could be avoided if they were preceded by more detailed preparation and a process of sifting to prevent repetitions and stale communications. The fact that measures have now been taken and a permanent organisation created to look after all these questions is a new departure and the most salient fact connected with the Sixteenth International Congress of Medicine.

At the final session of the Congress Dr. F. W. PAVY, on behalf of the Government of Great Britain, tendered a formal invitation to the Congress to hold its next meeting in London in 1913. The invitation was accepted with acclamation, and cordial messages to that effect were forwarded to King Edward and to his Minister for Foreign Affairs. This is the first occasion on which the British Government has officially invited a scientific gathering to meet in this country.

With regard to the scientific fruits oft he Congress, a very large number of papers were read and discussed in the 21 sections in which the work was done, and they will be available in due course in the official publications. It was obviously impossible for us to give a full account of the proceedings of so large a body, as they will fill probably over a dozen ponderous volumes; and whilst presenting our readers with abstracts of the papers dealing with the subjects of most general interest in each section, we selected for particular notice the proceedings devoted to naval and military medicine, tropical medicine, and questions of quarantine as being of true international importance.

Five addresses were delivered in plenary congress, and of these the most important were given by Dr. E. F. BASHFORD, director of the Imperial Cancer Research Fund, on "Oancer

in Man and Animals," which we printed in full, and by Professor M. KUTNER of Berlin, who spoke on Post-Graduate Courses. Professor BACCELLI of Rome took for his subject "Intravenous Medication," whilst the discourses of Professor Laveran of Paris and of Professor J. Lobe of Berkeley, U.S.A., were concerned with the "Etiology and Prevention of Tropical Diseases" and with "Parthogenesis in its Bearing on the Physiology and Pathology of the Cell" respectively.

We recorded the resolutions passed by the Section of Maritime and Tropical Medicine to the effect (1) that dysentery in any of its forms should be added to the list of compulsorily notifiable diseases in all countries, and (2) that the attention of the Powers be called to the new danger for the spread of plague and cholera caused by the opening of the Hedjaz Railway and asking that the subject may be submitted to the consideration of "a competent assembly." We also recorded the excellent suggestion advanced by Lieutenant-Colonel W. G. MACPHERSON, R.A.M.C., that the nations should adopt a uniform system of colour tallies indicating the severity of a wounded combatant's condition.

A joint discussion which excited much popular interest was held by the Medical, Surgical, and Gynæcological Sections on the Treatment of Appendicitis. The balance of opinion was in favour of a more expectant treatment than has recently been in vogue, but there was not the wholesale condemnation of operative treatment that was recorded freely by the daily press. Other important debates were held on Immunity and Anaphylaxis and on the Application of Laboratory Work to Clinical Medicine, with special reference to Sero-Diagnosis, which were fully summarised by one of our special correspondents.

We have alluded to the general address on Post-graduate Courses delivered by Professor KUTNER. Therein he gave an account of the post-graduate institution over which he presides in Berlin, and maintained that not only should medical men look upon post-graduate study as a normal part of their life-work, but that they should be given all reasonable opportunities of obtaining it without payment in or near their places of abode and at hours convenient to their practice. On the day following this address the medical representatives of 15 Governments, which had been in communication on the matter with the Foreign Office at Berlin, met under the presidency of Professor WALDEYER, with the result that an International Committee for Medical Post-graduate Courses was formed, with a constitution and status, which we set forth at length. This committee, the inauguration of which is in no small measure due to Professor KUTNER and his Berlin colleagues, will, it is hoped, lead to the realisation of a scheme that will not be the least valuable result of the Sixteenth International Congress of Medicine.

THE THIRD INTERNATIONAL CONGRESS OF THE MEDICAL PRESS.

On August 27th, in one of the finest meeting halls of the Budapest Academy, representatives of 13 different national associations of the medical press assembled—first as a congress, with doors open to all comers, then, on the following day, as the general assembly of the International Association of the Medical Press. The Congress was received by Professor M. DE LENHOSSÉK, President of the Hungarian Association of the Medical Press, who was able to give a very good account of the growth of the organisation in his own country. So thoroughly did the Hungarians believe in the international character of the advance of science that they published their medical papers in two and sometimes in three languages. Professor Dr. Kálmán Müller, President of the Sixteenth International Congress

of Medicine, was also present to welcome the journalists. The principal subject discussed was the question of advertisements and "puffs." On this the British section presented a report describing the resolutions carried on the subject by the British Medical Association and asking that they should be endorsed by the Congress. In principle no objection was raised, but in practice it was pointed out that the law varied in different countries. The British delegates complained that articles written in good faith were utilised by commercial houses in spite of the protests of authors and publishers. Such reproductions were against the English copyright law, though it was difficult to institute proceedings. The French and the German representatives found that it was not practical to prevent such practices. Dr. LUCAS-CHAMPIONNIÈRE related that he had even been advertised as recommending some particular make of absinthe. He had written a paper on the benefit derived from the use of oxygenated water in medicine. This was quoted in favour of absinthe to which the manufacturer had added some oxygen. Nevertheless, the lawyers whom he consulted advised him not to proceed against this absinthe dealer. There was also a great deal of discussion as to what constituted a réclame or "puff." It was agreed that this was an article in which the author was not allowed to criticise but was obliged to praise the drug, invention, method of treatment, or whatever other subject he might have to write about. A réclame therefore is a venal article which the author or the paper is bribed to write and to publish. The British position on this subject, whereby it is held that the author of a "puff" if he cannot prove an infringement of copyright is guilty of unprofessional conduct, was adopted.1 The British scheme for a permanent commission to manage international congresses was also adopted. Several speakers expressed the opinion that the representatives of the medical press who had attended and described congress after congress were most likely to be able to advise with the wisdom that springs from experience. To appoint a permanent commission for the Medical Congress was not enough. There should be a federation of the permanent commissions of the various international congresses of the allied sciences, such as tuberculosis, hygiene and demography, alcoholism, housing of the poor, school hygiene, deontology, and the congresses on special diseases. By such a mutual understanding congresses could at least be prevented from meeting at the same time. It was quite impossible for the press to be efficiently represented at two congresses held at the same moment. One great good has resulted from the international organisation of the medical press to which the Budapest medical congress bore witness. Formerly the representatives of the press received but scanty attention and little was done to facilitate their very difficult task. Now at Budapest two special rooms were placed at the disposal of the press, and the secretaries of each section collected as far as possible the MS. summary of the different speeches which each speaker was invited to write, and placed them in the press room at the disposal of the journalists. Care was also taken to invite the press representatives to all the functions, visits to institutions, and excursions which they might desire to describe. Among other matters discussed was the question of summaries of important original articles. The Congress voted that such summaries should be translated into one or more of the international languages so that they might be more widely quoted. Finally, it should be mentioned that Professor DE LENHOSSÉK entertained all the press representa. tives at a banquet, so that the social side as well as the business purpose of this international journalistic gathering was not neglected.

Our Sanitary Commissioner visited Egypt at the beginning of the year and sent in a series of reports on sanitation in Egypt. The first subject treated was the water-supply of Cairo. Here an unfortunate enterprise has proved a great disappointment. Some two miles below Cairo and on the banks of the Nile 22 deep wells were dug which it was calculated would yield 4000 cubic metres each of pure potable water. In a little while, however, this water proved altogether unfit for domestic purposes. Manganese and iron in the water favoured the growth of the crenothrix that helped to block the pipes and turned the water black. Engine boilers were damaged, linen was stained, and vegetables could not be cooked. Finally, the supply from the wells steadily decreased, while the water was so unpopular that a great number of people preferred to drink the unfiltered Nile water. Yet the one object in digging the wells was to prevent the drinking of Nile water, for it is impossible to prevent the contamination of this river. But the people prefer the Nile water, which they have drunk for thousands of years, while in the minds of many it is sinful to drink well water, which they called "buried water." In these circumstances, we were pleased, though not surprised, to hear that the Egyptian Government has decided to abandon the wells and revert to the Nile, carefully filtering its waters.

SANITATION IN EGYPT.

The next most important subject was the drainage of Cairo. Even before the British occupation there were plans and schemes for the drainage of this historic city, but they all fell through, and the subsoil continued to be more and more contaminated by leaking cesspools. A scandalously high death-rate even among the well-to-do European population testified to bad sanitation; indeed, the soil has become so filthy that now, when at last it has been decided to build sewers, the people are panic-stricken with the fear that the digging up of the earth for the sewers will cause an epidemic. Mr. C. CARKERT JAMES, who planned and carried out the drainage of Bombay, is now undertaking the drainage of Cairo. His scheme and the difficulties that had to be overcome to secure its adoption were fully described in these columns. In the flat central districts where there is no natural fall the Shone system will be employed to raise the sewage and to propelit forward to the main gravitation sewer, which after draining several important suburbs, and notably Heliopolis Oasis, has its outfall in the desert 16 miles north of Cairo. Here is land which cost nothing, and its soil is admirably adapted for a sewage farm. Indeed, if properly managed, the produce of the cultivation of what is now mere desert should suffice to cover the working expenses of the sewage scheme. If all the slop and waste water, as well as the crude sewage, can be conveyed rapidly out and away from Cairo in water-tight sewers this will be an immense benefit, particularly as the subsoil will then be able gradually to purify itself. But there will still remain the domestic drainage difficulty. We know in England how long it has taken to teach certain sections of the population to make cleanly use of the sanitary accommodation provided. Fortunately, in Egypt the Mahomedan religion inculcates cleanliness as a part of religious ritual; therefore it is only necessary that these excellent precepts should be adapted to modern and mechanical processes to ensure the prompt and safe removal of all filth.

In Egypt, under British guidance, an admirable service has been organised for dealing with outbreaks of plague and cholera. Unfortunately, from motives of petty economy, there has been some interference with the measures taken at Alexandria. Here a new danger has arisen. The road of invasion is no longer merely from Mecca, Suez, and the South generally. There is cholera in the Caucasus also, and pilgrims from Mecca can now reach by train the Mediterranean ports of Syria. Here they embark for Alexandria, and a system of medical examination had been introduced at this port to meet this danger. It only cost £1800 per annum, but required many months to organise. For some unaccountable reason the Minister of the Interior disallowed this small sum and the Port of Alexandria is deprived of the very effective protection that had been so economically organised.

The danger caused by the pilgrimages, the need of pure water-supplies and of efficient drainage are all subjects on which much has been written and said by those who have discussed public health probems in relation to Egypt. But our Special Sanitary Commissioner brought prominently forward a very serious question which has been strangely neglected. One of the greatest necessities in Egypt is cheap fuel. In the absence of such fuel the cleanly habits of the people, by a strange contradiction, led to the dangerous accumulations of the foulest dirt. There are no less than 57 hammams, or public baths, at Cairo. These are more assiduously frequented by men, women, and children than would be the case in a European and Christian town. The institution of the hammam, or Turkish bath, should therefore contribute to maintain the general cleanliness of Cairo. The reverse is the case, and this is entirely due to the want of cheap fuel. The household refuse produced by the 644,000 inhabitants of Cairo suffices to fill daily some 600 carts. The baths take 189 of these cartloads of rubblish daily and store them in yards and dilapidated houses at the back of the baths. This rubbish is used as fuel to warm the water for the baths. For the convenience of the population the baths are situated in the centre and the most densely populated parts of Cairo, and here also are these vast accumulations of rubbish. As this waste contains fragments of food, of fruit, of vegetables, bones, and various forms of garbage, it attracts a vast population of stray cats, and the dirt they make adds to the foulness of the refuse. Naturally these accumulations provide a breeding ground for the flies that constitute one of the plagues of Egypt. The bath furnaces are also used for cooking; large jars containing beans and oil are placed in the ovens to cook. For at home what little cooking is attempted has to be done on a smouldering fire of evil-smelling dried dung. Thus cheap fuel is a really important necessity from the public health point of view.

Such refuse as is not consumed as fuel for the baths is for the most part dumped down on the immediate outskirts of the town. Thus and in the course of time perfectly flat suburbs have been converted into hilly districts. seem to be offshoots of the Mokattan range of mountains are in reality enormous dust-heaps. Here there is so much organic matter fermenting that spontaneous combustion is taking place, and many of these hills are on fire. The heat can be felt through the soles of the explorers' boots, and it is only necessary to push a walking stick down a distance of a foot or so to make a little chimney through which the smoke will come. There are acres and acres of land covered with mountains of dirt that dominate Cairo. From them dangerous dust and poisonous flies are wafted towards the dwelling houses, infecting the food on which the dust and the flies settle. To make matters worse, it is proposed to build on some of these rubbish deposits.

The scavenging service, though still somewhat undermanned and cramped for want of sufficient funds, is admirably organised. This, in the first instance, was the work of Mr. A. H. HOOKER, F.I.C., a pupil of the late CHARLES HEATON, formerly the Special Sanitary Commissioner of THE LANCET. It is now energetically and ably continued by Mr. Felix E. Powell, who has an army of

street sweepers and scavengers marshalled together in military fashion. But when he has collected all the rubbish he is obliged to sell it to the baths or dump it on the outskirts of the town. There is, it is true, a destructor, but it can only consume 30 tons per day, whereas the rubbish carted away daily from Cairo weighs about 210 tons. More than 300 cubic metres of dangerous, dirty matter is accumulated every day in the immediate neighbourhood of Cairo. Yet there is the desert close at hand, which could be rendered fertile if water as well as this rubbish could be spread out where to-day there are but arid sands.

In conducting his investigations our Special Sanitary Commissioner received courteous assistance at the Ministries of the Interior and of Public Works and from the Director-General of the Public Health Department. The Khedival Medical Society, the Egyptian Institute, and the Association of the European Press all received him with great cordiality, and many persons in their individual capacity offered to help. There was evidently a genuine desire to hear an independent opinion upon the sanitation of the city. We sincerely hope, and, indeed, have reason to believe, that the reports we published will help forward the cause of sanitary progress.

SANITATION AT SEA.

Continuing his studies of sanitation at sea our Special Sanitary Commissioner profited by his visit to Egypt to travel on one of the Austrian-Lloyd steamers and to call at the head offices and the shipbuilding yards of the company at This line enjoys the highest reputation for the courteous and careful attendance bestowed on passengers and for its excellent cuisine. This is a very important consideration. Hunger does not create the gastronomic arts-it renders them less necessary; but to tempt the appetite of a sea-sick traveller real culinary skill is required. The Austrian-Lloyd has created a school of cookery of its own which is a mixture of the French and Viennese schools with a purely Italian dishthrown in as an occasional diversion. The directors take the keenest interest in this school. There is a hierarchy of chefs and under chefs, and the staff is kept together because those who persist and acquire the rank of chef become entitled to old age pensions. The ships are for the greater part English built, but not of the most recent type. There is nothing novel in the methods of ventilation employed. On the other hand, the crews have better quarters than on English ships. The British law only insists on 120 cubic feet of space, whilst the Austrian law stipulates that seamen shall have 180 cubic feet and firemen 150 cubic feet. For the stewards there is better provision made, especially in respect to baths and douches, than is the case on many English passenger ships. Needless to say, that from the sanitary point of view it is most important that the attendants who serve the food and make the beds should be clean and in good health. New ships are to be built by this company at an early date, and then the most recent methods of warming and ventilation are to be applied. When returning from Egypt our Commissioner travelled by the French Messageries Maritimes and remained some days at Marseilles so as to make inquiries concerning this line. The Austrian-Lloyd and this French company work together. so that passengers to Egypt can go by the one route and return by the other; thus many very interesting places may be visited by those who can afford to stop on the way. The accommodation in the poorer quarters of these ships are better than what will be found on the older British ships. and the cuisine is good. At Marseilles our Commissioner was also able to visit and describe the sanitary laundry where all the linen and bedding belonging to the 68 ships of the Messageries Maritimes are washed.

HOSPITAL FUNDS.

The receipts of the three hospital funds of London have been, perhaps, adversely influenced by the state of political unrest which has dominated the country during the past year, but the result of the appeals to the charitable public cannot be called unsatisfactory. The administrators of KING EDWARD'S Hospital Fund for London have been able to distribute £150,000, an aim towards which they have been steadily working; and the year therefore, as was pointed out by the PRINCE of WALES at a meeting of the council of the Fund, held at Marlborough House on Dec. 13th, represents a landmark in the history of the Fund, as did the year 1900, when £50,000 was distributed, and the year 1903, when £100,000 was distributed.

The Metropolitan Hospital Sunday Fund.

During the year the Council of this Fund has lost by death the valuable services of the Rev. Dr. RIGG, one of the founders of the Fund, the Rev. Dr. MARKS, SIT THOMAS SMITH, SIT STEPHEN MACKENZIE, and Mr. THOMAS WAKLEY, the late Editor of THE LANCET.

Under the presidency of Sir George WYATT TRUSCOTT, the late Lord Mayor, the year's collection reached a total of £72,650 8s. 5d. It is gratifying to notice that this year there has been a larger number of contributing congregations than previously—namely, 2070. The collections in the various places of worship resulted in a sum of £39,143, being £1096 less than in 1908. The Metropolitan Cathedral of St. Paul's headed the list with £4326. The following are the largest collections from contributing churches and other places of worship: Christ Church, Lancaster Gate, Rev. Prebendary GURDON, £1001; St. Michael, Chester-square, Rev. J. G. McCormick, £761; St. Mary, Bryanston-square, Rev. Prebendary WAKEFIELD, £440; St. Mary Abbots, Kensington, Rev. Prebendary PENNEFATHER, £439; Holy Trinity, Chelsea, Rev. H. R. GAMBLE, £410; St. Peter, Eaton-square, Rev. Prebendary STORRS, £378; St. Jude, South Kensington, Rev. Prebendary EARDLEY WILMOT, £291; St. Paul, Onslow-square, Rev. Prebendary WEBB-PEPLOE, £286; St. Nicholas, Chislehurst, Rev. J. LE STRANGE DAWSON, £265; St. Paul, Knightsbridge, Rev. F. L. BOYD, £261; All Saints, Ennismoregardens, Rev. J., H. F. PRILE, £255; St. George, Hanoversquare, Rev. Prebendary Anderson, £246; St. Peter. Oranley-gardens, Rev. W. S. SWAYNE, £237; Church of the Annunciation, Portman-square, Rev. B. D. D. SHAW, £213; St. Peter, Vere-street, Rev. R. W. BURNABY, £212; St. John, Paddington, Rev. E. P. Anderson, £206; St. James, Piccadilly, Rev. Canon McCormick, £204; St. Columba, Pont-street, Rev. A. FLEMING, D.D., £241; Theistic Church, Swallow-street, Rev. Chas. Voysey, £175; West London Synagogue, Rev. Dr. MARKS (the late), £315; Great Synagogue, the CHIEF RABBI, £240; Essex Church, Kensington, Rev. F. K. FREESTON, £243; Westminster Chapel, Rev. G. CAMPBELL MORGAN, £209; Union Chapel, Islington, Rev. W. HARDY HARWOOD, £118; St. Paul Presbyterian Church, Westbourne-grove, Rev. R. ROBERTS, £101; St. Andrew's Presbyterian Church, Frognal, Rev. R. MACLEOD, £100; Greek Church, the Archimandrite, £89; Brompton Oratory, Rev. H. D. S. BOWDEN, £58; Church of Immaculate Conception, Farmstreet, Rev. C. NICHOLSON, £51; Victoria Park Christian Evidence Association, Mr. T. Cole, £67; Dutch Church. Austin Friars, Rev. S. B. DE LA FAILLE, £50; German Church, Camberwell, Rev. Professor HACKMANN, £55; Ferme Park Chapel, Hornsey, Rev. Chas. Brown, £64: Wanstead Society of Friends, Mr. THEO. GODLEE, £43; Wesley's Chapel, City-road, Rev. D. T. Young, £52; Gordonsquare Catholic Apostolic Church, Mr. H. S. HUME, £26.

The total income from the estate of the late Mr. George Herring amounted to £26,861. Mr. William Herring gave a donation of £1000, and "Delta" sent his thirtieth donation of £200. A further £2000 was received from the executors of the late Mr. Herring the balance of the legacy of £10,000 bequeathed by him to the Fund in 1901, and a legacy of £900 was received under the will of the late Mr. Edwin Gayford, and £500 on account of the bequest of Mr. C. E. Layton, deceased. The Fund has recently lost two valuable contributors by the death of Mr. J. Mackrell, who as "Delta" gave £200 annually for the past 30 years, and Mr. Lewis Mond.

A report of the annual meeting of the Fund will be found on p. 1934 of our present issue.

King Edward's Hospital Fund for London.

The present year, as has been said, marks a step in the continued progress of this Fund. The total amount received up to Dec. 9th, after payment of expenses, was £133,997 5s. 4d., which sum includes £19,000 collected by the League of Mercy. The largest donation received during the year was one of £4775 from the Franco-British Exhibition representing half the present available surplus. The annual subscriptions show a diminution. The amount available for distribution was £150,000, being £147,000 for London hospitals and £3000 for convalescent homes and consumption sanatoriums. The number of hospitals applying for grants was 103, as against 105 last year. As was pointed out by the PRINCE of WALES at a recent meeting of the council held at Marlborough House, the aim of the Fund has been to make an annual distribution of £150,000, the sum mentioned in the KING'S letter inaugurating the Fund; therefore the present year may be considered as a landmark in the history of the Fund. At the same meeting His Royal Highness called attention to the successful amalgamations of the Orthopædic Hospitals and the Hampstead and North-West London Hospitals, but regretted that the Throat, Nose, and Ear Hospitals had not yet amalgamated. The work of the Convalescent Homes Committee, which for many years was limited to the distribution of the generous donation of £1000 from the London Parochial Charities, has now been extended to dealing with the amount voted by the council for convalescent homes and consumption sanatoriums. "Considering," said His Royal Highness, "the enormous demand for accommodation in the country for consumption patients from the London hospitals, it is much to be regretted that the possible openings in this direction are at present so few. I trust that the managers of existing or of future sanatoria within reach of London will appreciate the readiness of the committee to enter into negotiations to secure' beds for the accommodation of patients from metropolitan hospitals."

Hospital Saturday Fund.

The annual income of the Hospital Saturday Fund, which was founded in 1873 for the purpose of obtaining help for the metropolitan hospitals and kindred institutions from those who were not reached through the operations of the Metropolitan Hospital Sunday Fund, now approaches, £30,000, which is obtained from some 8000 places of business. The annual report shows that help is obtained from practically every trade, friendly society, and club, the employés of the London County Council. the borough councils, the railway companies, the Metropolitan Water Board, the General Post Office, the Royal Arsenal, Woolwich; the Royal Small Arms Factory, Enfield Lock; the Royal Victoria Yard, Deptford; the Dock Companies, and so forth, and the members of the Metropolitan and City police. Since its foundation the Fund has collected and distributed among the medical charities of London £488,635. In recent years there have

been about 200 participating institutions. The Fund, recognising the great importance of early treatment in cases of tuberculosis and other chest diseases, has endowed beds at the Benenden Sanatorium, Kent; at the Mount Vernon Hospital, Hampstead, and its Sanatorium at Northwood; at the Fairlight Home, Hastings; and at the Eversfield Hospital, St. Leonards. 37 beds are at present endowed, the patients paying, as a rule, 7s. 6d. per week for the first six weeks, after which time the prices are arranged in accordance with the means of the patients and other circumstances. The sum thus received enables the Fund to assist many applicants who could not otherwise be relieved. During the present year the various departments of the Fund have made steady progress, and it is hoped that when the books are made up in January they will show a record collection for 1909. Up to Dec. 11th the total receipts of the Fund amounted to £20,442, as against £20,413 in the corresponding period of 1908.

THE CHICAGO STOCKYARDS REVISITED.

It will be remembered that in January, 1905, we published a series of articles which constituted the first effective revelation of the abominations practised in the Chicago stockyards. We use the word effective advisedly, because our denunciations were reproduced in Chicago, caused much discussion, and drastic reforms were consequently introduced the following August. The result was that, of all the meat condemned as unfit for consumption during the year, 85.5 per cent. was seized during the five months following upon the introduction of the reforms in question. It was in the course of the ensuing year, 1906, that Mr. UPTON SINCLAIR'S novel "The Jungle" appeared and brought the insanitary conditions we had described to the knowledge of a general and horrified public. Then Mr. ROOSEVELT and later the United States Department of Agriculture also took action and the criticism of this bureau on our report was fully dealt with on July 14th, 1906. Then the Legislature took the matter in hand and new laws were enacted giving the Government a better control over both food and drugs. After a lapse of four years our special Sanitary Commissioner returned in the early days of this year to Chicago to see and describe how far reforms had been realised. So world-wide an agitation it was only natural to expect would bring about many alterations. Unfortunately, the entire stockyards were planned in the absence of any sort of technical sanitary control, and no one concerned had any idea whatsoever of the conditions that should be imposed when slaughterhouses are built. No one seemed impressed with the principle that the provision of food is a public service and a public trust. Therefore the first object is that the food shall be clean and wholesome. The first object was to produce quickly and cheaply, so that the maximum profits might be secured. Therefore great factories were built that are most insanitary and absolutely unsuited for abattoir purposes. These still remain standing, but in many of them improvements have been effected. Many of the porous floors, where blood and filth leaked through and fell on the workers below, have now been cemented over and made watertight. The walls are also rendered watertight. The carcasses are now cleaned in a much more careful manner and a better system of waterbrush employed. The old wooden wheelbarrows or trucks which used to cost £7, and were so porous that they could never be properly cleaned, are being replaced by aluminium trucks that cost £17 and are perfectly cleansed by immersion in tanks of scalding water. In the early part of the year we published photographic illustrations of these details.

More marked is the vast improvement effected in the lavatory accommodation now provided for the workers. This usel to be filthy and dangerous, but is now as perfect as

good plumbing and careful ventilation can make it. One of the largest canning departments has been entirely rebuilt. Within the walls are throughout of white glazed enamelled bricks, the corners are rounded off, as in a hospital, there is plenty of light, the workers wear a clean uniform working dress, and a professional manicure is kept hard at work trimming the nails and attending to the hands of the young women employed to dress and pack the meat. Unfortunately, these sanitary principles are not applied throughout. By the side of some of the most perfect and modern appliances there still remain dark loathsome places that are quite unsuited for the dressing of human food. Many of the killing floors are still far from watertight, there are cracks and crevices where dirt can secrete itself, and worn, battered, softened, spongy wood that constitutes an uncleansable harbour for germ life.

In the United States of America, as, indeed, is also the case in England, the number of abattoir inspectors is absolutely insufficient. But the Chicago scandal has brought about a great improvement in the States, of which there is unfortunately no counterpart in Great Britain. At the commencement of the year 1906 the Federal Government employed 411 veterinary inspectors. Towards the end of the year 1908, that is two years later, the number of inspectors was 2290, of whom 702 were veterinarians. The force at Chicago was 344, of whom 108 were veterinarians. Yet in spite of this doubling of the forces they are still absolutely insufficient. On one killing floor, going backwards and forwards from animal to animal, the veterinary inspector walks from seven to eight miles in a day and is constantly stooping to examine the viscera. The descriptions we published give other details clearly establishing the fact that the staff of veterinary inspectors is altogether insufficient.

Our Commissioner dealt with the stockyards proper--that is, the yards where great stocks of live cattle and sheep are gathered together. Here no improvement has been attempted. The pens are for the most part in the open air, separated by planks of rough wood that is not even whitewashed. No precaution whatsoever is taken to prevent the spread of disease among the animals. When cattle come from a part of the country that is infected they are placed in pens separated from the ordinary and neighbouring pens by a roadway which is only 15 feet broad. The platform on which they land from the trains also consists of unpolished planks and no attempt is made at systematic cleaning. None of the regulations which usually apply to cattle markets are in force here. It does not seem as if the necessity of any special care has been realised either by the owners of the stockyards or by the sanitary authorities. From all this it will be seen that the denunciations published in these columns have borne fruit and that welcome reforms have been applied. But this only points to the necessity of continuing in the same manner to expose the defects that still survive so that they, in their turn, may be swept away.

LOATHSOME BEDDING.

At the commencement of the year we had occasion to draw attention to the dangerous character of the material employed for making beds and stuffing furniture. In other countries flock beds are not popular and are rarely used. At Glasgow, Mr. Peter Fyfe examined 3163 beds and found that 78 per cent. were made of common flock, and there is no reason to believe that Glasgow differs in this respect from other towns. Therefore the composition of flock is a matter of considerable importance. From both the chemical and the bacteriological point of view the flock of these Glasgow beds was found to be more

contaminated than the crude sewage of Glasgow. " The bacteria in one gramme of the worst specimen of unwashed flock amounted at blood heat to 4,500,000, in Glasgow crude sewage they numbered 197,000, and in the Loch Katrine drinking water 75." The fact is that flock is made by the tearing to pieces of old rags, old clothes, old bits of carpet—in fact, any sort of worn-out useless tissue. This naturally is not only very dirty material, but it may contain specific pathogenic germs, as it includes sometimes bandages that have been used for dressing wounds and unwashed underlinen soiled by persons suffering from typhoid fever and even from cholera or plague, for rags are imported from distant countries. The only safety depends, therefore, on effective disinfection of such material. The general process of manufacture is to beat these rags up in running water by which they are cleaned, though the water may be contaminated. After rinsing, the rags are dried in kilns where the heat should reach 210° F., and these two operations are supposed to ensure not only perfect cleanliness, about which there can be no doubt, but also sterilisation. Only when this has been done are the rags, &c., torn to pieces by machinery and reduced to fluff or flock. To make a single bed 30 pounds and a double bed 45 pounds of such flock are required. At the wholesale price of $1 \ddagger d$. per pound the larger bed costs $56 \ddagger d$. Our attention, however, was called to the fact that if the rags were at once converted into flock, without any previous washing or drying, the uncleaned flock could be sold with as much or more profit at \$d. per pound. Thus the material to stuff the mattress of a double bed would not cost more than 331d. For the sake of 2s. per bed, the public were asked to run grave risks, and even when acquainted with the danger, and ask for and express their willingness to pay for clean flock, have no guarantee that they obtain it. All these facts, with details and photographic illustrations, were set forth by our Special Sanitary Commissioner, who inspected mills where the raw material is washed and clean flock made, and other mills where there is no washing process, while specimens of clean and of uncleaned flock were analysed in our laboratory. The results clearly showed that the latter could not be used with safety.

THE BENEVOLENT AGENCIES OF THE PROFESSION.

The various benevolent agencies of the profession have carried out their good work unostentatiously during the past year, and it is perhaps owing to the fact that financial help is rendered without undue publicity that many of the provincial medical benevolent societies have to deplore a paucity of members. From the brief accounts that are given below it will be seen that all the societies are worthy of support, while some of the older ones are so well endowed that the advantages offered to members are far beyond any that can be given by insurance companies. One point to which we wish to draw special attention is an excuse for ceasing to subscribe which is sometimes advanced by an old subscriber-namely, that a decreasing income is a justification for the withdrawal of his subscription. One moment's consideration will show that such a financial position is the strongest possible argument for continuing to subscribe, hence the maintenance of the subscription should be managed at all costs. Those who reside in a county in which there is a medical benevolent society would do well to write at once to the honorary secretary for particulars as to membership, bearing in mind that in having the opportunity of joining such a society they are in the majority of cases reaping the benefit of the hard work, the loyal support, and the generous benefactions of those who have gone before them. In other words, membership of most of the medical

benevolent societies is a privilege of which those medical men who are more or less dependent upon the practice of their profession should be but too eager to avail themselves. If mechanics can see their way to save from 1 guinea to 2 guineas a year to contribute to their provident societies, and many thousands regularly do this, surely medical men ought to manage to follow their example. Several of the provincial medical benevolent societies appeal for contributions from persons who are not of the medical profession; but whilst they are perfectly justified in doing this, medical men should show that they are themselves doing their best to support their own societies.

The British Medical Benevolent Fund.

This society makes grants of money to distressed members of the profession, their widows or orphans, and provides annuities for them after they have reached the age of 60 years. The report of the committee presented to the last annual meeting shows that in the grant department there was last year an increase of £193 in the receipts, the total amount of grants distributed being £1727. It further shows that the annuity department was satisfactory, the number of annuitants having increased by three, bringing the total number up to 126. The amount distributed in this department was £2459. The grants are paid out of the subscriptions and donations of the year, and are made either in single sums or in monthly instalments, the amounts given ranging from £5 to £20. The legacies and large donations are invested, and it is from the income derived therefrom that the annuities are paid. The membership subscription is 10s. a year, and a donation of £5 constitutes a life member. The honorary secretary of the Fund is Mr. W. E. SARGANT, St. Bartholomew's Hospital, London, E.C. A guild has recently been formed in connexion with this Fund to make it more widely known and to supplement its work by giving help and practical sympathy to its beneficiaries of a more personal character than is possible in the case of the parent fund. Contributions may be forwarded to the honorary treasurer, Dr. MAY THORNE, 148, Harley-street, London, W.; parcels of clothing should be sent care of Miss RUTH WEST, 11, Chandos-street, Cavendish-square, London, W.

Society for Reitef of Widows and Orphans of Medical Men.

The report for the past year states that there are 286 members, which is but a very small proportion of the medical men who are eligible for membership. The subscription is 2 guineas a year, 25 annual payments constituting a life member. Membership is open to any registered medical practitioner who at the time of his election is resident within a radius of 20 miles from Charing Cross; but should any member move beyond the limits he does not forfeit his membership. The invested funds amount to £100,071, bringing in annually £3121 interest; subscriptions and donations amounted to £645. As the society disbursed last year in grants £3017, the value of membership is verv great, hence the directors urge upon members of the profession, especially the younger ones, the desirability of joining the society. The secretary is Mr. E. J. BLACKETT, 11. Chandos-street, Cavendish-square, W.

THE LANCET Relief Fund.

The twentieth annual report of the almoners of this Fund states that the amount distributed since its inauguration in 1889 is £6119. Last year the number of applications for assistance received was 48, but 19 of these had either to be rejected as being outside the scope of the Fund or to be declined for other reasons; 9 of the forms of application sent out were not returned to the secretary, probably owing to the fact that the applicants realised that they were not eligible for the benefits, and the remaining 20 applicants were assisted by gifts or loans of money ranging from £5 to £25. As hitherto, the assistance was rendered in some cases within

a few hours of the application being received, and in more than one instance the financial help enabled the applicant to keep his practice together when pressing monetary difficulties would otherwise have broken up his home and ruined his chance of making a livelihood. The almoners once more emphasise the fact that the Fund is not intended to relieve persons who are in what may be termed a chronic condition of distress, but solely for cases of sudden emergency, where timely financial help is likely to result in permanent benefit. It will therefore be a kindness if those who are asked to recommend cases will bear in mind that poverty alone is not a claim for help from this Fund; if it were, the available funds would be exhausted in the first month of the year. The almoners are the President of the Royal College of Physicians of London, the President of the Royal College of Surgeons of England, the President of the General Medical Council, and the Editor of THE LANCET. The secretary is Mr. C. GOOD, THE LANCET Office, 423, Strand, London, W.C.

Royal Medical Benevolent Fund Society of Ireland.

The sixty-seventh annual report of this society states that grants were made by the committee amounting to £1166, and that subscriptions, donations, and bequests amounted to £748. In moving the adoption of the report last June the President of the Royal College of Surgeons in Ireland stated that there are approximately 3000 members of the profession on the Medical Register in Ireland, but there are less than 500 contributors to the society for which he was appealing. He said that the old story of increased expenditure in awards and of diminished receipts in subscriptions was much more marked that day. The contribution that made a subscriber to the Fund was so small that no man had an excuse for not being able to help it, at some time or other, at any rate. He attributed the lack of support given to the society to the fact that many medical men do not know of the existence of the charity, and many more do not realise the value and importance of the charity and of the work done. The subscription for membership is 1 guinea annually, or for life membership £10 in one payment. The secretary is Dr. CHARLES M. BENSON, 65, Lower Baggot-street, Dublin.

Royal Medical Foundation of Epsom College.

At the last annual general meeting of the governors the council presented a satisfactory report, showing that there was a surplus on the ordinary income and expenditure account last year of £432. The fact is emphasised that a sum of £4500 must be obtained annually by means of voluntary contributions in order that the council may maintain the full number of 50 pensionerships of £30 a year for aged members, or widows of members, of the medical profession and the 50 foundation scholarships providing board, education, and clothing free of charge at Epsom College for necessitous sons of medical men. There are also 25 other beneficiaries whose annuities are provided out of special funds, and 17 pensioners have their annuities increased from other funds, the amount being raised in 14 cases to £50 a year. The council is erecting a new gymnasium, new music rooms, and a new workshop, and are providing a central heating plant having sufficient power to heat all the new buildings, together with Granville House, the large school, and the chemical laboratory. These extensions and improvements, which are now nearing completion, will probably cost over £8000; but though the sum is large the council feels assured that a consistent and definite scheme of extension is the most economical course that can be followed. They urge upon all friends of the institution to do their best to secure fresh annual subscribers to the Foundation, since death removes annually many who have been staunch supporters. The secretary is Mr. J. B. LAMB, 37, Soho-square, London, W.

PROVINCIAL SOCIETIES.

Birmingham Medical Benevolent Society.

The eighty-seventh annual report shows that in 1908 there was a falling off in subscriptions of £54 as compared with 1907, but it is explained by the fact that in the latter year a large number of arrears were paid up. The total number of benefit members for the year remained unchanged. The invested funds amount to £15,940; the total of the grants voted in 1908 was £757. The directors draw attention to the very large number of practitioners in the district who have not yet availed themselves of membership of the society. The value of the relief granted can be appreciated from the following cases: a surgeon's widow received in grants £1295 after only £7 7s. had been paid in subscriptions; a widow received in grants £1247 after £15 15s. had been paid in subscriptions; an invalided member received £686 after paying £15 15s. in subscriptions. The annual subscription is 1 guinea; the honorary secretary is Dr. J. E. H. SAWYER, 93. Cornwall-street, Birmingham.

The Devon and Exeter Benevolent Medical Society.

This society was founded in 1806, and has invested funds to the value of £3287. The subscriptions for the past year amounted to £40 19s., and the total of the annual grants voted was £70. The subscription for membership is £1 1s. annually, or life membership may be obtained by paying a donation of £21. The honorary secretary is Mr. ELGAR DOWN of Wingfield House, Stoke, Devonport. The annual meeting is held in one of the principal towns of the county, as may be appointed by the president.

Essex and Herts Benevolent Medical Society.

This society, which was instituted in 1786, granted in 1908 £320 in seven grants, ranging in amount from £20 to £80, and received £98 in subscriptions and donations. The capital is represented by £11,103 2½ per cent. Consols. The membership subscription is 1 guinea annually, but persons not of the medical profession who subscribe half a guinea per annum are constituted governors of the society and are entitled to vote in all its transactions. The secretary is Mr. Vernon Austin of Hertford.

Kent Benevolent Medical Society.

This society, which was instituted in 1787, is actively engaged in carrying on its good work. The funded property of the society is represented by £3650 2½ per cent. Consols and £1200 India 3 per cent. stock; a sum of £330 was spent last year in grants. There are 105 members who subscribe £1 1s. annually; and the value of membership may be seen from the fact that since the foundation of the society no fewer than six families have received relief exceeding £1000 in amount, whilst 16 others have received £500 and upwards. There are three honorary secretaries—namely, for the eastern district, Mr. H. G. SADLER of Canterbury; for the middle district, Dr. CHARLES E. HOAR of Maidstone; and for the western district, Mr. H. C. BURTON of Lee Park. The assistant secretary is Mr. James Wiltshier of 25, St. George's-place, Canterbury.

Lincolnshire Medical Benevolent Society.

At the 106th annual meeting of this society held last July grants to the extent of £120 were voted to widows of members in the substantial sums of £30, £40, and £50 respectively. There are 93 subscribing members of the society, the annual subscription being 1 guinea. The value of the investments is £3505; the honorary secretary is Dr. W. A. CARLINE of Lincoln.

Medical Benevolent Society for the East and North Ridings of Yorkshire (including the City of York).

The first annual report of this society shows that good progress has been made. There are over a hundred

members and many more medical men have promised to become subscribers, so that the prospects are favourable. The balance in the hands of the treasurer is £164; the annual subscription is 1 guinea. The committee expresses the hope that a personal canvass will soon be made, with a resulting large increase in the membership. It also appeals for donations and benefactions from those who are not members of the medical profession, observing that the neighbouring West Riding and Lincolnshire benevolent medical societies have received very large sums in this way. The honorary secretary is Dr. EDWARD TURTON of 1, Albionstreet, Hull.

Medical Charitable Society for the West Riding of the County of York.

The eighty-first annual report of this society states that although the list of applications for assistance is slightly shorter than that of the preceding year, the general tendency for many years has been in the direction of a rapid and almost annual increase. Whilst the society is in a position to meet any immediate requests for assistance, it must be remembered that the sum received from annual subscriptions in recent years has not equalled one-half the amount distributed in grants, and that as membership increases so does liability to claims for help. At the last annual meeting grants were made to the extent of £1625; the total value of the investments is £29,464; the annual subscription for membership is 1 guinea. The honorary secretary is Mr. MICHAEL A. TEALE of Park-square, Leeds.

The Norfolk and Norwich Benevolent Medical Society.

This society was established in 1786 for the relief of members who are incapacitated from continuing to practise, and of their widows and orphans if these do not marry. Full particulars as to the conditions of membership can be obtained from the honorary secretary, Mr. C. J. MURIEL, 42, St. Giles-street, Norwich. The annual meeting is held in the month of July.

The Surrey Benevolent Medical Society.

This society was instituted in 1812, and the last statement of account shows that in 1908 a sum of £90 was distributed in three pensions of £30 each, a sum of £70 was expended in grants to members, and three scholarships for girls and two extra scholarships for boys cost £224. The society has the right in perpetuity of nominating four scholars to Epsom College. The invested funds amount to £11,875, and there are 61 members. The entrance fine is £5, and the annual subscription £2, but the latter may be commuted according to a fixed table. The subscription is not payable for longer than 30 years, after which time the subscriber is considered a life member. A payment of £30, in addition to the entrance fine of £5, constitutes the contributor a member for life. The honorary secretary is Mr. W. A. BERRIDGE, of Redhill, Surrey.

The Sussex Medical Benerolent Society.

In submitting the fourth annual report the executive committee states that the relief of necessitous members will begin, in accordance with the rules, on May 1st, 1910. There are at present only 62 subscribing members and the invested funds amount to £302. The committee, therefore, appeals for new members in order that the society may become a prosperous one. We cordially endorse its appeal, and trust that medical men in Sussex will endeavour to secure contributions from those outside their profession, since this policy has helped to establish some of the strongest medical benevolent societies. The importance of a substantial reserve fund cannot be over-estimated. The annual subscription is 1 guinea; the secretary is Dr. L. A. PARRY, of 83. Church-road, Hove, Sussex.

HONOURS TO MEDICAL MEN.

Strictly speaking, there were no New Year honours, but early in January Surgeon-General Bomford, C.I.E., the Director-General of the Indian Medical Service, was promoted to a Knight Commandership of the Most Eminent Order of the Indian Empire, while Major Hood Orr, I.M.S., civil surgeon of the Bohraich District United Provinces, and Lieutenant-Colonel John Tasman Waddel Lerlie, I.M.S., Sanitary Commissioner with the Government of India, were appointed Companions of the same Order.

Birthday Honours.

The June list of honours contained the names of Mr. HENRY MORRIS and Sir DYCE DUCKWORTH, upon whom baronetcies were conferred. Lieutenant · Colonel W. B. LEISHMAN, R.A.M.C., received a knighthood; Surgeon-General LIONEL DIXON SPENCER, I.M.S., was made a Knight Commander of the Bath; and Surgeon-General HAYWARD READER WHITEHEAD, R.A.M.C., and Colonel DE BURGH BIRCH, A.M.O. Territorial Force, were made Companions of the same Order. Lieutenant-Colonel ROBERT NEIL CAMPBELL, I.M.S., and Mr. EDGAR THURSTON, L.R.C.P., received Companionships of the Order of the Indian Empire; Professor WILLIAM JOHN RITCHIE SIMPSON, M.D., C.M. Aberd., F.R.C.P. Lond., a Companionship of the Order of St. Michael and St. George; and Dr. TEMULJI BHIKAJI NARIMAN the Kaisar-i-Hind gold medal. Sir HENRY MORRIS, the late President of the Royal College of Surgeons, is well known to all medical men as surgeon, anatomist, and authority on medical education, as well as for his munificent gifts to the Middlesex Hospital and his energetic work in support of Epsom College. Sir DYCE DUCKWORTH is well known as a consulting physician to St. Bartholomew's Hospital, and has been medical referee to the Treasury since 1894 and treasurer of the Royal College of Physicians of London since 1884. Lieutenant-Colonel Sir W. B. LEISHMAN is distinguished for his researches in bacteriology and protozoology, as appears from other sections of this annual summary. Surgeon-General Sir LIONEL DIXON SPENCER is an honorary surgeon to His Majesty. Surgeon-General HAYWARD READER WHITE-HEAD is principal medical officer, Southern Command; Lieutenant-Colonel ROBERT NEIL CAMPBELL is officiating Inspector-General of Civil Hospitals in Eastern Bengal and Assam; and Mr. EDGAR THURSTON is the superintendent of the Government Central Museum of the Province of Madras. Professor WILLIAM JOHN RITCHIE SIMPSON has done admirable public service in plague.

In the November list were the names of Mr. HENRY WILLIAM NEWTON, L.F.P.S. Glasg., Mr. JAMES MATTHEW MOODY, L.R.C.P. Edin., M.R.C.S. Eng., Mr. GEORGE HERBERT POLLARD, M.P., M.D., C.M. Edin., who received the honour of knighthood, and Mr. JAMES AUGUSTINE HARAN, M.D. Dub., who was made a Companion of the Most Distinguished Order of St. Michael and St. George. Sir HENRY WILLIAM NEWTON is the "father" of the city council of Newcastle and has done excellent work in the interest of public health. Sir JAMES MATTHEW MOODY has been the medical superintendent of Cane Hill Asylum for a quarter of a century. Sir GEORGE HERBERT POLLARD, M.P., is a barrister-at-law of the Inner Temple, and has been a Member of the Eccles Division of Lancashire since 1906. Mr. JAMES AUGUSTINE HARAN is a medical officer of health at Mombasa in the East Africa Protectorate.

Royal Victorian Order.

In connexion with the visit of the King of Portugal to this country His Majesty the King conferred upon Dr. DE MELLO BREYNER, Physician in Ordinary to King

Manuel, the Commandership of the Royal Victorian Order. During the year Colonel Charles Edward Harrison, honorary surgeon to His Majesty, Brigade-Surgeon-Lieutenant-Colonel, Grenadier Guards, was made a Commander of the Royal Victorian Order, and Fleet-Surgeon Cyril James Mansfield, R.N., was appointed a Member of the Fourth Class of the Order.

Forcian Orders.

Mr. EDWARD S. CRISPIN, M.R.C.S. Eng., L.R.C.P. Lond., Director of the Soudan Medical Department, Khartoum, received from the Khedive of Egypt the Imperial Ottoman Order of the Osmanieh of the Fourth Class. Mr. ARTHUR ANDREW MORRISON, M.D. Aberd., surgeon to the Deaconesses' Hospital at Alexandria, had conferred upon him by the German Emperor the Insignia of the Fourth Class of the Royal Order of the Crown. Mr. EDWARD DOUGLAS MADGE, M.R.C.S. Eng., L.R.C.P. Lond., received from the King of Roumania the Cross of Officer of the Star of Roumania. Lieutenant-Colonel J. W. T. GILBERT, R.A.M.C. (Territorial Force), received the silver medal of the Order of "Orange-Nassau" from the Queen of the Netherlands. Mr. H. STANLEY TURNER, M.R.C.S. Eng., L.R.C.P. Lond., was decorated by the King of the Hellenes with the Knighthood of the Royal Order of the Saviour. Dr. GEORGE OGILVIE received the Insignia of Knight of the Royal Order of Isabel la Catolica from the King of Spain. Staff-Surgeon ELYSTAN GLODRYDD EVELYN O'LEARY, R.N., who was on the Sutlej which was at Messina at the time of the earthquake, received the Italian Order of St. Maurice and St. Lazarus.

Among our confrères in other countries who have received honours are: Dr. RAMON Y CAJAL, the eminent Madrid anatomist, who has been appointed a Senator of the Kingdom of Spain; and Dr. SCHUMAN LECLERCQ, Carlsbad, Austria, who has been made Chevalier of the French Légion d'Honneur.

OBITUARY.

From the beginning of this year, up to and including our issue of Dec. 18th, we have had the mournful duty of inserting in our columns exactly 100 special obituaries of wellknown and highly appreciated medical men, including the notice of one whom we in this office cannot fail constantly to remember—our late Editor, Mr. THOMAS WAKLEY. We now merely recall to the minds of our readers, in order of the date of death, the names of some of those whose great records or living influence make their departure from among us a feature of the year. On the first Monday of 1909 it was known in Edinburgh that Dr. ARGYLL ROBERTSON had died in India on the previous day. He was born in Edinburgh in 1837. In 1869-70 he published in the Edinburgh Medical Journal a paper on "Eye Symptoms in Spinal Disease." It was the observations made at that time which led to his world-wide reputation and to his name being attached to the pupil phenomena of tabes. Dr. GEORGE EASTES, who died on Jan. 23rd at the age of 67, started in 1868 upon his 40 years of general practice in the West of London. He was an admirable journalist as well as a successful general practitioner, and his failure by but a few votes to secure a place on the Council of the Royal College of Surgeons of England was much regretted. Dr. JOHN LINDSAY STEVEN died at Glasgow after a short illness. He was a thorough exponent of internal medicine in all its branches, was recognised in Glasgow as one of the best of teachers and consulting physicians there, and was an influential member of the General Medical Council. Dr. CHARLES HENRY FELIX ROUTH died in London on Feb. 19th at the age of 87. He was throughout his long professional life absorbed in the study of gynecology, and was an early exponent of the

doctrines of Semmelweis. He read many papers and was a fearless debater and eloquent speaker. Professor DAVID JAMES HAMILTON, who died on Feb. 19th, was emeritus professor of pathology in the University of Aberdeen, having been appointed in 1882. He was known to the whole medical world by his textbook of pathology. Dr. Peter Horrocks, who died on Feb. 28th at the age of 56, was consulting obstetric physician to Guy's Hospital, and had been president of the Obstetrical Society. The Editor of THE LANCET, THOMAS WAKLEY, died on March 5th. He had worked together with his father, the late Mr. THOMAS HENRY WAKLEY, in the conduct of this journal for a little over 20 years, and the files of the paper testify to his energy, his fairness, his kindness, and his sense of responsibility. Dr. ARTHUR GAMGEE died in Paris on March 29th. He was born in 1841 at Edinburgh, and was, when quite a young man, emeritus professor of physiology at the Victoria University, Manchester. He came to London in the late "eighties" as physician to St. George's Hospital, but his physiological works and writings form his claim on our attention. He was without doubt one of the leading physiologists of the country. Mr. CLAUDIUS GALEN WHEELHOUSE died on April 9th. He was consulting surgeon to the Leeds General Infirmary, an important worker on the General Medical Council, and an active supporter of the British Medical Association. He was one of the three Direct Representatives for England and Wales on the General Medical Council, and during his ten years of office was an invaluable intermediary between different schools of thought on the Council. Mr. JAMES HARDIE, who died on March 27th, was consulting surgeon to the Manchester Royal Infirmary, and sat for some time on the Council of the Royal College of Surgeons of England. Dr. THOMAS CRAWFORD HAYES was emeritus professor of obstetric medicine at King's College, London, and consulting physician-accoucheur and physician for diseases of women, King's College Hospital. Dr. CHARLES BELL TAYLOR, who died on April 13th in his eightieth year, was an ophthalmic surgeon and enjoyed a deserved repute for industry and ingenuity. He was a man of strong opinions, which were not always accepted by his profession, even when their honesty and ingenuity were admitted. Mr. THOMAS WILLIAM NUNN, who also died on April 13th, was consulting surgeon to the Middlesex Hospital. A sound surgeon and a popular teacher, he had been in his day a well-known consultant. Mr. SIMEON SNELL, who died on April 17th during his term of office as President of the British Medical Association, was a frequent contributor to these columns. He was ophthalmic surgeon to the Sheffield Royal Infirmary and professor of ophthalmology in the University of Sheffield, and his work on his subject, especially in relation to diseases of occupation was famous. Dr. WILLIAM W. IRELAND, who died on May 17th, was born at Edinburgh in 1832, was a well-known writer on alienism, an ardent student of history, an independent thinker, and the author of a great book, "The Blot upon the Brain." Professor Daniel John Cunningham, who died on June 23rd in his sixty-first year, was professor of anatomy in the University of Edinburgh and the best and most learned exponent of his subject in the kingdom. Mr. EDMUND MARSHMAN RUSSEL RENDLE who died on June 23rd in his seventy-seventh year, was consulting surgeon to the Royal Plymouth Eye Infirmary, and was a prominent figure in the "Three Towns." Dr. ALEXANDER FRASER, who died on July 25th. aged 56, was the able professor of anatomy at the Royal College of Surgeons in Ireland. Dr. ARTHUR FOXWELL who died as the result of a bicycle accident on August 4th. was born in 1853. He was physician to the Queen's Hospital, Birmingham, and professor of therapeutics in the

University of Birmingham, where his premature death has left a great gap. Dr. HENRY RADCLIFFE CROCKER was born in 1845 at Brighton, and was physician to the Skin Department, University College Hospital. He had won a very great position as a dermatologist and was an important supporter of the British Medical Association. Sir STEPHEN MACKENZIE, who died on Sept. 3rd in his sixtyfifth year, was consulting physician to the London Hospital and the Royal London Ophthalmic Hospital, and had for many years occupied a prominent position as a clinical teacher and an original investigator. Dr. JOHN MILSOM RHODES, who died on Sept. 25th at Didsbury, was an ardent supporter of Poor-law reform. Sir THOMAS SMITH died on Oct. 1st at the age of 76. He was honorary serjeant-surgeon to the King and consulting surgeon to St. Bartholomew's Hospital and the Hospital for Sick Children, Great Ormondstreet, London, and commanded in his profession, and deservedly, the greatest affection and respect. Dr. WILLIAM RIVERS POLLOCK, who died on Oct. 5th at the early age of 50, was obstetric physician to Westminster Hospital and senior physician to Queen Charlotte's Hospital. Dr. JOHN HERBERT WELLS, who died on Oct. 16th at Ditchling at the early age of 30, became accidentally and fatally infected with anthrax. The circumstances of his life and death will be remembered by our readers, and a fund which has recently been raised as a tribute to his memory is still open in our columns. CESARE LOMBROSO, whose studies in psychiatry and criminal anthropology are known to the whole world, died on Oct. 19th. Mr. HENRY HUGH CLUTTON, who died on Nov. 9th at the age of 59, was senior surgeon to St. Thomas's Hospital, London. He was a man of strong character and lofty aims and a notable teacher. Sir WILLIAM THOMSON. honorary surgeon to the King, late President of the Royal College of Surgeons in Ireland, and senior surgeon to the Richmond, Whitworth, and Hardwicke Hospitals, died on Nov. 13th. He was born in 1843, made many contributions to the literature of his profession, and took an active part in educational work. Mr. ROBERT MARCUS GUNN, who died on Nov. 29th at the age of 59, was senior surgeon to the Royal London Ophthalmic Hospital, Moorfields. An accurate observer and student of nature, he was a recognised master of his subject. Mr. CHARLES ROBERT BELL KEETLEY was senior surgeon to the West London Hospital, and made a name for himself by his practical work in surgery, by his literary labours, and by his life-long association with the great Hammersmith charity. Dr. WILLIAM BRAMWELL RANSOM, who died on Dec. 9th at the untimely age of 48, was senior physician to the Nottingham General Hospital and physician to the Sherwood Forest Sanatorium for Consumption. The details of his career were published in THE LANCET too recently to need recapitulation.

We cannot close this account without referring to the sad death from an Alpine accident on Jan. 13th of Dr. John Evan Spicer and the yet more tragic death of Dr. Cawas Lalcaca, who was assassinated while trying to defend the life of Sir Curzon Wyllie at the Indian reception on July 1st in London. Lastly, we must record the death of the doyen of Irish medicine, Dr. George Ellis, who died on Jan. 26th in his 100th year.

Annotations.

"Ne quid nimis,"

A PRESCRIPTION FOR CHRISTMAS.

THE Christmas season undoubtedly has a good tonic effect upon the people which none appreciates more than the members of our profession. It has come to be regarded as a time for good cheer, and no matter how tiresome the circumstances may be which are forced upon us by life's ironies, or what painful incidents have in the past been associated with the season, there is good feeling engendered at this time of joyousness; routine is for a while relieved, a certain freshness is given to the daily round, differences of opinion are sunk, and a charitable spirit prevails. Is it, by the way, hoping for too much that the season of good-fellowship should leave some effect upon the manners and methods of political partizans? The country is being compelled to make up its mind in the course of a few days as to issues of vast importance. Patriotic and personal feelings are deeply involved. There are honest men on both sides; there are well-wishers of the people in each camp. Is it not possible for the political orator to remember this, and to infuse into his rampagings a little of that urbanity which the season calls for? To do so will be good tactics, for our minds are attuned just now to such approaches. It may not be easy to trace exactly why this sense of exhilaration and well-being comes with the advent of Christmas, for the psychological factors concerned are not simple. But the main point is that the mental state does everybody good, and the annual festivity is just as excellent an institution as the prescription of the physician which gives tone and vigour to the struggler in life's race. There is no need nowadays, thanks to the good sense of the people and the counsels of their medical advisers, to moralise about the evils of a stupid indulgence in food, alcohol, and tobacco on a festive occasion such as the present. Practically everybody realises the great physiological advantages of being wise on a merry occasion and the disadvantages of being a fool. Many more persons than formerly feel where use ends and abuse begins, and they act sensibly accordingly; and so far from its being a crime to make the season festive by enjoying, on a little extended scale perhaps, the creature comforts of life some decided good is done to both the mental and physical health of the individual. The festive season may, therefore, be welcomed which brings cheer to thousands, which induces the generous and charitable desire to help all to share in the season's joy, which serves to brace the mental and physical functions of the community at large, giving it the opportunity of relinquishing its business and its worries for a time, to start again refreshed and ready for "the trivial round, the common task." The prescription "A Merry Christmas" is sound so long as the "signature" of good sense is observed.

DISINFECTION AFTER CANCER.

WE have received a letter from a correspondent urging the necessity for careful disinfection of rooms which have been inhabited by patients suffering from malignant disease. She points out that few people would be willing knowingly to inhabit a bedroom in which a patient had died from malignant disease when no attempt had been made to disinfect the room. We think there is something to be said for the contention of our correspondent; but it must be remembered that it has never been proved that infection can occur in malignant disease. There are many cases recorded which are suggestive of this, and it would be unwise to deny

University of Oxford.—The name of Alan E. Taylor, Trinity College, was omitted in the list of successful candidates in the examination in pathology for the second B.M. degree.—In congregation on Dec. 17th the degree of B.M., B.Ch., was conferred upon D. C. Dobell; Christ Church; H. G. Butterfield, Wadham College; C. J. Z. Jessel, University College; and S. F. Moore, Trinity College.—The Hebdomadal Council has appointed Professor Francis Gotch, M.A., D.Sc., Fellow of Magdalen College, a member of the committee for the election of honorary medical officers to the Radcliffe Infirmary.

the possibility of such an occurrence when medical science is not agreed upon any theory of etiology of malignant disease. All will agree that the individual cells of malignant growth are capable in certain circumstances of transference from one animal to another of the same species, and therefore no one can deny the possibility of infection. In a very similar position stands tuberculosis. While we possess no direct evidence that the presence in a house or a room of a patient suffering from tuberculosis ever does give rise to the disease in another person, the whole teaching of hygiene of the present time is in favour of preventing the dissemination of the organism to which tubercle is due. Therefore we cannot but think that it is desirable that the room and the furniture which have been used by patients dying from malignant disease should be thoroughly cleansed and disinfected, and especially should this be done when the malignant growth has been situated on a surface so that a discharge has come from it. It is easy to demand proofs of the risk arising from such discharges; it is difficult to produce them. Nevertheless, we feel that it is only in accordance with the principles of modern hygiene to endeavour to the best of our ability to disinfect all discharges from persons who have suffered from malignant disease. This is not the same as saying that we ought to insist by legislative enactment that such disinfection should be carried out, but medical thought is tending in a direction which would be supported by public sentiment.

TYPHOID CARRIERS IN THE ARMY.

THE Director-General of the Army Medical Service has presented to Parliament his second report on the Transmission of Enteric Fever by the "Chronic Carrier" in a White Paper, which includes a series of charts illustrating the progress of the cases under treatment by specific vaccines. The report concludes with the following recommendation of the Advisory Board: "That since arrangements are now being made for early treatment on discovery of these cases, it is desirable that any man ascertained to be a 'carrier' should, after a period of observation in England not exceeding three months, be discharged from the service, unless he elects to remain in hospital for treatment. When any man is discharged the medical officer of health for the district in which he will reside should be notified."

THE METROPOLITAN HOSPITAL SUNDAY FUND.

THE Right Hon. Sir John Knill, Bart., the Lord Mayor, presided over the annual general meeting of the Metropolitan Hospital Sunday Fund, which was held at the Mansion House on Dec. 17th. In moving the reception of the report, which was unanimously adopted, Sir John Bell referred to the loss which the Fund had sustained by the deaths of the Rev. Dr. Marks, Sir Stephen Mackenzie, the Rev. Dr. Rigg, Sir Thomas Smith, and Mr. Thomas Wakley. Dr. Rigg was one of the founders of the Fund. Within the last few weeks two staunch supporters of the Fund had passed awaynamely, Mr. J. Mackrell, who under the pseudonym of "Delta" had contributed £200 annually for the past 30 years, and Mr. Lewis Mond. During the year about £70,000 had been divided among infirmaries, hospitals, and institutions. The collections among the various religious bodies amounted to nearly £40,000. The Rev. Hardy Harwood, who seconded the motion for the adoption of the annual report, said that the contributing congregations were larger than in previous years-namely, 2070. The Rev. S. Lewis supported the motion. He explained that the hospital for which he pleaded last year (the National Anti-Vivisection Hospital) had not accepted a grant owing to a misunderstanding as to some non-official remarks

which were made by a speaker at a previous meeting. Hospital Sunday was fixed for June 12th, 1910, and the Council was re-elected with the addition of Sir George Wyatt Truscott, Mr. J. H. Morgan, the Rev. Morris Joseph, and the Rev. D. J. Waller to fill vacancies. The Rev. S. Lewis withdrew a motion to the effect that the committee of distribution should be mainly elected by the constituents of the Fund at the annual meeting, which was intended as a protest against the suppression of reasonable criticism on the part of the constituents of the Fund. The Lord Mayor said that the right of criticism was undoubted and he thought had never been refused.

UNDER the will of the late Dr. Charles Graham, formerly professor of chemical technology at University College, London, the residue of his estate has been left to the Senate of the University of London in trust to form "The Charles Graham Research Fund." The income therefrom is to be devoted to the expenses of any approved medical research undertaken by any teacher or student of the School for Advanced Medical Studies connected with University College Hospital, and in certain instances to the provision of research scholarships in pathology at that school of £200 a year value, tenable for two years.

WE would direct the attention of graduates and students of the late Royal University of Ireland to a notice which appears in our advertising columns. As the first meeting of Convocation must take place within six months from the date of the dissolution of the Royal University of Ireland, it is very advisable that application for registration as graduates should be made without delay. All information may be obtained from Dr. Joseph McGrath, Registrar of the University, the National University of Ireland, Dublin.

Dr. R. J. Collie, medical examiner to the London County Council, has issued a report on the health of the employees for the five years from August, 1904, to August, 1909.

A TELEGRAM from the Governor of Mauritius to the Secretary of State for the Colonies has reported 17 cases of plague with 13 deaths during the week ending Dec. 16th.

PROPOSED MEMORIAL TO PROFESSOR D. J. CUNNINGHAM.—Some time ago a circular was issued signed by the Principal of the University of Edinburgh and the Presidents of the Royal Colleges of Physicians and Surgeons of Edinburgh, stating that it was proposed that steps should be taken to institute some memorial of the life and work of the late Professor Cunningham, and calling a meeting to be held on Dec. 15th. At this meeting it was decided that Edinburgh should coöperate with Trinity College, Dublin, where steps were also being taken with the same object in view. What was spoken of was a medallion and a medal in anatomy. A small committee was appointed with Professor Crum Brown as convener.

ROYAL ALBERT HOSPITAL, DEVONPORT.—At the recent annual meeting of the subscribers of the Royal Albert Hospital, Devonport, the report stated that for the year ended Sept. 30th last the in-patients numbered 771, an increase of 50 compared with the previous 12 months. In the casualty department 2696 cases had been treated, against 2413 in the previous year. 943 patients were treated in the out-patient ophthalmic department, compared with 913 in the preceding 12 months. 208 patients were sent to the Pearn Convalescent Home, being 31 in excess of the previous year. The financial statement showed the expenditure was £4768, and that an unfavourable balance of £587 remained. The President (Lord St. Levan) alluded to the support of the working men, who had subscribed £615 during the past year, and made a strong appeal for increased financial support.

SOME CONSIDERATIONS OF MEDICAL EDUCATION.

VIII.1

Neither Teacher nor Taught at Fault.—The "Block" System.— The Science Student at the Public School.

In the previous chapter it was pointed out that it was allowed on all hands that the medical curriculum was over full, or, to put it in other words, that the statutory time of five years did not seem to be sufficient to allow a fair proportion of students to obtain their qualifications. Something over 80 per cent. of the students occupy more than the statutory five years in their attempts to obtain a place on the Medical Register, and it is impossible to believe that any large proportion of these men owe a check to their professional career to inherent faults of their own, to idleness, slackness, or stupidity; and it is equally impossible to attribute this deplorable waste of effort to remissness on the part of teachers or frailty on the part of examiners. There are idle students, supine teachers, and incompetent examiners, but no one with any experience of the enormous pains now taken with regard to the machinery of medical education, or in the least appreciative of the earnest, absorbing, and generally ill-paid labours of the lecturers, will think for one moment that the radical trouble is any default on the part of teacher or taught.

With regard to the one-portal system, the suggestion that it would by its simplicity remedy the condition of affairs is interesting, but impractical because the advocates of this system have not, at any rate at present, sufficiently strong arguments to produce any effect either on the General Medical Council or on the legislature. The suggestion that the statutory time of the curriculum should be extended has also been dealt with, and most of us will be in agreement with what is apparently the opinion of the General Medical Council, that the time has not arrived for this. In the present position of affairs the curriculum is indefinitely extended, so that the failure of the students to meet the demands made upon them forms a practical equivalent to a statutory prolongation of the time of studentship, only this prolongation occurs in a disappointing and vexatious manner. There remains, lastly, to consider the advisability that the student should reach his medical school in a better state of preparation, so that he shall have much less trouble with his preliminary scientific subjects, and consequently more time to devote to his final subjects, and the importance of this point is enhanced by the fact that the General Medical Council has now adopted the view that for these official subjects a distinct period of not less than 24 months shall be kept sacred.

This means the formal introduction into the medical curriculum of the "block" system, which has many advocates and also many opponents. A large number of medical students having difficulty with their preliminary subjects, whether these are the ancillary subjects of chemistry, physics, and biology, or the directly professional subjects of anatomy and physiology, occupy more than three years of the statutory five years in study pursued in classrooms before they are free to attack without interruption the final subjects of medicine, surgery, and midwifery. It is certain that to a great many of these students time is of vast importance, so that they are unwilling (or their parents are unwilling for them) to postpone their introduction to clinical work until they shall have satisfied their examiners upon all the introductory subjects. To work at anatomy and physiology in the detailed way required by an approaching test examination leaves the student with but little leisure and aptitude for other studies, yet many students by industry and determination recover to a great extent the place which they have lost in the early part of the race, being able with success to conduct what are called overlapping studies. Remembering this, and

remembering also that a certain number of students are able to coach their fellows in the introductory subjects while working for the final subjects, it becomes a serious matter to compel all students to keep for any specified period the whole of their time free for clinical and pathological work. On the other hand, two years must appear to be the very minimum of time in which it is possible nowadays to acquire such a genuine knowledge of actual medical and surgical practice as would warrant any university or licensing body in granting a degree or a diploma to an applicant. Further, the pressure on the General Medical Council to make the examination in the professional subjects even more wide-ranging than it is at present-to include, for example, such subjects as anæsthetics and electro-therapeutics—has to be taken into account. Those who see no harm in a certain amount of overlapping possess a strong argument in the fact that, scientific medicine being built upon a foundation of anatomy and physiology, little but good can come of a certain amount of fusion of studies. But the more the final subjects of the curriculum tend to become multiplied or specialised the more remote becomes the connexion between them and the details of anatomy and physiology taken as a whole. All these considerations no doubt weighed with the General Medical Council in deciding that at least the last two years of the student's time should be spent in clinical and pathological work, but upon this decision follows the difficulty that now the first three years of the student's time may not prove sufficient for his preliminary scientific studies, including his anatomy and physiology.

It seems probable that here, as far as England is concerned, the public schools will come to the rescue. Inasmuch as every medical student is compelled to pass an entrance examination of a general character before commencing his medical studies—which means that he must go to school somewhere—if more of his time at school were spent in definite preparation for a medical career his curriculum would be lengthened without more money being spent than would otherwise have been spent on his education. That is to say, that the very legitimate objection on the part of the medical student, or usually of his parents and guardians, to spend an increased sum upon training for a profession which, already by no means a cheap one to enter, offers in return no great pecuniary prizes, would be to some extent met. With the continuous expansion of our knowledge in every branch of science it is at least possible, and to many it appears inevitable, that the general education of boys and girls destined for one or another of the scientific callings must give way at an earlier period than has hitherto been necessary to the special training which is to be the stock-intrade of their various careers. This means, as has been pointed out in these columns, that we may have to ask the schoolmaster to hold the balance squarely between the claims of science and the claims of the humanities upon the school hours of those of the coming generation who are to practise the profession of medicine. The influence which a capable teacher of the elements of science can exert over a lad during the last two years of school life is very great, for by the time the pupil has reached that period of his education he should have learnt how to learn, and his mind should be in its most receptive state—so much plastic material ready to be moulded into methods of accurate observation, and indued with a right appreciation of the experimental method and all that it entails. If the student brings such a training with him to a medical school he has gained a solid and practical advantage from his school-days beyond the expansion of his mind and its equipment with a store of knowledge. It is to be desired in most cases that the school-boy, who has elected to follow medicine, should receive a grounding in the principles of chemistry and physics at least before he passes the "arts examination," which is the portal to his professional studies. Of course, if time is of no object to the student he can acquire this grounding after spending a full school life in general education, but if he desires to become a medical man at the average age (and this is now about 26 years) he will make his path easier by beginning his scientific work soon after the age of 16. Many of the English public schools are now perfectly able to instruct their boys in physics and chemistry, and some of them claim to be able to give better instruction than will be obtained at certain of the medical schools, but there is still difficulty at most

¹ Nos. I., II., III., IV., V., VI., and VII. were published in THE LANCET of Oct. 23rd (p. 1232) and 30th (p. 1301), Nov. 13th (p. 1459), 20th (p. 1531), and 27th (p. 1616), and Dec. 4th (p. 1694) and 11th (p. 1766), 1909, respectively.

public schools as regards biological teaching. This for one reason has made the General Medical Council look with no great favour on the instruction of schoolboys in the preliminary scientific subjects, while recognition of schoolboy instruction as part of the statutory course must always seem unfair to Scottish, and particularly to Irish, students, where no system exists of big public schools which possess laboratories and an equipment of teachers and material for a scientific education.

But the General Medical Council has no reason whatever to be concerned whether the schoolboy takes up scientific subjects or no before he begins his statutory career: all that the Council requires is that he should begin this career by passing some examination in Arts. What has to be thought of, then, is this. The intending medical student must go to school, and his schooling must be paid tor. When he is a student he will take six or seven years to obtain his qualifications, mainly owing to his difficulties with the pre-liminary subjects. But if he works at those subjects at school he will probably only take the statutory five years to get qualified after joining a medical school, while his schooling will cost no more than if he had devoted himself to the humanities. Will his schooling be worth less? Probably not. Since the old days when apprentices were bound to a trade with many years of indenture, sometimes commencing at 12 years of age, no calling in England has seemed to require this kind of segregation except the calling of the naval officer. The tactics of the navy with regard to its officers have always been to "catch them young," but no other trade or profession at the present time considers this proceeding necessary. However partial the attempt in this direction may be, the strictly professional part of a schoolboy's educa-tion would have to be undertaken at the risk of making him as a professional man narrow. By inducting him into a purely professional educational course before he has completed his general instruction we must undoubtedly run a risk of depriving him of something that is valuable. None the less, such is the difficulty caused by the present overcrowded state of the medical curriculum, and such is the obvious waste of effort implied in the long delay which the students undergo in obtaining their qualifications, that it is quite possible that reform will come in this direction. If English students should benefit by a general move among those intending to practise medicine towards joining the modern side of a good public school, we can only conceive that the example would be followed elsewhere. And the fact is undoubted that students who are capable of proceeding to pass the examination in the preliminary scientific subjects on arriving at a medical school have an enormous advantage over their compeers. It is impossible not to sympathise with the desire of the science masters in public schools to be in proper accord with the General Medical Council and have their instruction recognised as counting as part of the statutory time of the student's career, but their instruction is none the less valuable because it is given preliminary to and not as part of the medical curriculum. At present the science masters can, as a matter of fact, dispense with the recognition of the Council if they can obtain that of any statutory body granting medical qualifications, but we see no reason why the student intending to be a medical man should not do at any rate the first year of his scientific studies before joining the medical school and concurrently with his general studies, but he must be prepared to do this as a voluntary act. It must be a matter of arrangement between him and his parents to secure for him an early start, and we cannot expect the General Medical Council to take cognisance of these schoolboy studies while only certain divisions of the United Kingdom can supply the necessary machinery.

The argument behind most of the proposals which have been discussed for the reform of the educational curriculum of the medical student was that subjects for the final examinations were neglected because the students had to spend too much time over the earlier subjects. The number and variety of the suggestions to meet the abuse prove how general was the feeling calling for these different expressions. The Education Committee of the General Medical Council showed in its interesting reports the enormous value of the work which it has done, and the Council has supported these efforts and brought order for the time being into the curriculum. By deciding definitely that 24 months must be spent by the

student in uninterrupted clinical and pathological work, the Council has taken a step which should certainly ensure much less waste of effort and of time, and much less disappointment and expense at the final end of the curriculum; but there necessarily remain for consideration the difficulties attached to the teaching and learning of the earlier subjects. Attention henceforth will be centred more upon the problems connected with these subjects, and it is probable that the position of the science masters in the public schools who desire to begin the education of the medical student when he is in his sixteenth year will receive greater attention than heretofore.

ASYLUM REPORTS.

The Twentieth Annual Report of the Asylums Committee as to the London County Asylums for the Year ending March 31st, 1909.1—This voluminous report contains a vast mass of statistics relating to the ten institutions under the control of the London County Council. The figures relating to direct admissions show that the number of patients admitted directly from the parishes have remained fairly constant for the past seven years, ranging from 3439 in 1902 and 3686 in 1903 to 3588 in 1907 and 3613 in 1908. The value of these figures as a guide to the incidence of insanity is somewhat discounted owing to their dependence on the amount of accommodation available, and for this reason a comparison with earlier years is useless. Now, however, that the bulk of London certified lunatics are housed in the county asylums the numbers of direct admissions should from 1908 onwards form an approximately correct index to the fluctuations in occurring insanity in the county. A table showing the duration of the present attack prior to admission indicates that while 1473 out of 3450 direct admissions (excluding congenital cases) were admitted within one month of the onset of the illness. no less than 508 had been mentally disordered for more than 12 months before admission, and 106 of these for more than five years. The number of patients discharged "recovered" shows a continued tendency to decline, the figure for 1908 being lower than in any year since 1902. Of the 1179 patients discharged recovered 8.06 per cent. were over 60 years of age, and 5.51 per cent. under 20. In 8.39 per cent. the attack was of less than three months' duration, and in 26.46 per cent. the attack has lasted from three to six months. Of the 1179 recoveries 621 had been suffering from recent mania and recent melancholia. Out of the large mass of registered lunacy the medical superintendents of the asylums consider that only 3.04 per cent. of the patients have a favourable prospect of recovery, 6.01 per cent. being doubtful and 90.95 per cent. unfavour-The deaths continue to show a decreasing proable. portion when calculated on the average population of the asylums. This may partly be accounted for by the accumulation of chronic cases of insanity, which. having passed the period of possible recovery, remain inmates until their deaths, often at advanced ages, thus swelling the bulk on which the proportion is calculated. In the 1540 deaths recorded, as many as 36.04 per cent. were over 60 years of age, and of these 17.14 were over 70. The report contains the conclusions of the Asylums Committee upon the report of the Royal Commission upon the Care of the Feeble-minded. Most of the recommendations of the Royal Commission embody principles which are commended to the committee by its experience in dealing with the insane, and, indeed, many follow the lines of suggestions which the committee has itself put forward at various times. committee is of opinion that the amount of laborious work laid upon it, should the recommendations be realised in legislation, would be incalculable, but it recognises that it is only by measures which deal comprehensively and thoroughly with feeble-mindedness that the tide of insanity can be stemmed. We regret that we can derive little hope from the report that the Mental Hospital devised by Dr. Henry Maudsley and for the purposes of which he has given a magnificent donation is likely to be shortly established. The necessity for an easily accessible situation in connexion with the clinic and out-patients' department, which it is intended shall be attached to the hospital, has rendered the task of selection of a site very difficult.

- THE THERAPEUTIC VALUE OF LIQUID AIR AND SOLID CARBON DIOXIDE.

To the Editor of THE LANCET.

SIR,—I notice in your issue of Dec. 11th the letter from Dr. Stopford Taylor and Dr. MacKenna concerning the value of liquid air and solid CO₂. Both in hospital and private work I have now had considerable experience of the value of both these remedies, and consider they have a marked therapeutic value and that there is no difficulty in regulating the pressure in either case. The liquid air we use after the method as given by Dr. Stopford Taylor, the snow with the aid of various-sized cupping-glasses, and tubes containing a sort of jack in the box spring of wool, tow, &c.

With either remedy the greatest care is necessary with delicate skins in order to prevent a serious burn, but even when this has occurred the scar tissue has been supple and of a fairly natural colour. We also prefer the liquid air to the snow, but find the former very much more costly than the latter. For lupus erythematosus I prefer to use zinc ions, but for capillary nevi and moderately shallow venocapillary nævi use nothing now but either the snow or air, applied once or twice to five or six times, and for from five to ten and up to 40 seconds exposures. We have found it difficult to get adult patients with large port-wine stains to stand enough of the treatment to get really good results. It is the after-soreness that they object to rather than the temporary pain during the applications. This is lessened by excluding air from the affected area by means of collodion or dusting powders, but is not prevented. Latterly we have only treated a small area at a time, but this of course enormously increases the period of treatment. The cleanest results that I have had in the treatment of nævi are with radium, but the expense of the salt is a drawback, and particularly so in hospital work, and, furthermore, with babies constant attention is necessary to prevent the slipping away of the applicators or buttons from the affected area.

I am, Sir, yours faithfully,

Reading, Dec. 16th, 1909.

W. T. FREEMAN.

ABDOMINAL CRISES IN DIABETES.

To the Editor of THE LANCET.

Sir,—Dr. Nestor Tirard's interesting communication in your issue of to-day and the preceding annotation upon the same subject impel me to add a few brief observations of my own. Miss A—B—B—aged 27, a fever hospital nurse, on August 18th last entered my consulting-room in a state of great debility, having been compelled to resign her hospital appointment from sheer bodily weakness. Her general aspect and the odour of her breath permitted a rapid diagnosis (which the urine examination amply corroborated—specific gravity 1032; sugar in quantity) of diabetes. There had been amenorrhoze for seven months.

From the above date, at intervals of a week or so, she was under my observation; the urine, despite rigid diet and medicine (principally sodæ salicyl.), remained at the same high specific gravity both morning and evening, although her weight improved from 7 stone to 7 stone 7 pounds. Among the marked features of her case were the following: Eczema of the eyebrows; vivid "hectic" flush of the cheeks; a red, dry, papillated, very sore tongue, and a typical breath-odour which pervaded my room at each visit with an unusually sickening persistence. At the beginning of November she was able to have a change of air, at Brighton. Her means limiting her visit she returned home, much benefited by the change, about Nov. 17th, and called upon me to report herself as feeling "ever so much better and stronger."

One week later, at 8 A.M., I was urgently summoned to see her. I found her in a condition of marked drowsiness, with dilated and sluggish pupils, rapid shallow breathing, and a disability to heed those around her, in fact, in a condition of commencing coma. She answered my questions with semi-intelligence and was able voluntarily to yield me a specimen of urine for examination. This, tested, showed much less sugar; specific gravity, 1015.

Sodae bicarbonas by the mouth was administered almost immediately, but was as immediately returned. Two hours later the stupor was more marked, the pupils still dilated and sluggish, and a new symptom had appeared—abdominal pain. To locate this I gently percussed the bladder region to obviate any retention trouble, but there, and in the left iliac region, nothing abnormal was to be found. In the right iliac region, however, even the lightest touch produced cries of pain. For this I advised hot applications until my next visit. At 1 o'clock I was called again on account of the pain having become agonising. Being professionally engaged elsewhere I was unable to see her at the moment, and advised the family to call in the nearest medical man, Mr. Dalton Tacey, who kindly saw her and administered a hypodermic injection of morphia and atropine, and when I saw her later in conjunction with that gentleman she was in deepest coma, moribund, dying at 8 P.M.

The features of the case which struck me were: (1) The fall of the specific gravity with commencing coma; (2) the intensely rapid onset of pain in the right iliac region with no explanation of its cause on digital examination, unrelieved except by morphia; and (3) the long amenorrhæa and the rapid change from the "ever so much better and stronger" condition to the fatal termination. I much regret that in my hasty first visit I omitted to put my ophthalmoscope in my pocket and therefore was unable to view the fundi.

I venture these somewhat sketchy notes for your readers in the hope that each clinical observer of this diabetic phase may add his mite, thereby increasing the sum of truth and the benefit of future records.

I am, Sir, yours faithfully, Woodford Green, Essex, Dec. 11th, 1909. HUGHES R. DAVIES.

THE JOHN HERBERT WELLS FUND.

THE following is the seventh list of subscriptions to the John Herbert Wells Fund. Further contributions will be gratefully received by the Earl of Dalhousie and Mr. Julian G. Lousada, honorary secretaries and treasurers of the fund, at 16, Old Broad-street, E.C., or by ourselves at this office:—

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

The following appointments are notified:—Fleet-Surgeons: H. W. Macnamara, C. Bradley, A. G. W. Bowen, and J. C. Durston to the *President*, additional, for three months' hospital course; J. K. Robinson to the *Casar*; and J. Moore to the *Shannon*. Staff-Surgeons: E. T. P. Eames, W. R. Trythall, F. F. Lobb, J. Boyan, E. O. B. Carbery, and A. R. H. Skey to the *President*, additional, for three months' hospital course; C. H. Rock to the *Indus*; E. Arkwright to the *Blenheim*; J. E. H. Phillips to the *Endymion*; K. H. Jones to the *Dida*; J. Lindop to the *Excellent*; and W. J. Codrington to the *Cornwall*, on recommissioning. Surgeons: E. R. L. Thomas, W. C. B. Smith, T. E. Blunt, G. E. Hamilton, and H. S. Turner, to the *President*, additional, for three months' hospital course; J. Barrett to the *Detiance*, lent temporarily; W. N. Blatchford to the *Vernon*, additional, for the *Niger*; B. S. Robson to the *Haleyon*; J. Hadwen to the *Dominion*; J. C. Orwin to the *New Zealand*; and H. C. Devas to the *Cornwall*, on recommissioning.

ROYAL ARMY MEDICAL CORPS.

Captain Dudley S. Skelton, from the Seconded List, is restored to the establishment (dated Dec. 11th, 1909).

Captain A. E. F. Hastings has been detailed as medical officer of the first and second camps of artillery training at Bargarh.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Women Doctors and the Infirmary Board.

THE question as to whether women should be admitted to resident appointments at the Manchester Royal Infirmary has become a burning one. A recent report from the board of the hospital announcing its decision against the appointment of lady doctors to resident medical or surgical posts in the Manchester Royal Infirmary has called forth much criticism. Two of the adverse reasons given, that "the patients do not desire their services," and that the infirmary "cannot provide accommodation," have been treated with scant respect by the friends of those aggrieved. A local weekly paper says: "The report of the committee has been scathingly condemned and pitilessly analysed; its bad logic has been exposed, its departure from facts marked, and its weakness ridiculed." A committee has been formed to support the movement to "secure justice for the women doctors who ought not to be barred out merely for sex reasons." The Northern Association of Medical Women have discussed the matter. They meet the arguments of the board that no male patients and very few female patients preferred to be medically treated by a woman; that in a general hospital the services of medical women were not, upon the whole, as valuable and beneficial as those of men; that the board would not be justified in incurring the additional expense which would be necessary in order to provide accommodation for women medical officers. The reply is to the effect that the patients whose opinion was asked by those in authority at the infirmary were not in a position to give an unbiassed answer; that figures can be given from hospitals with mixed staffs to show that there is a demand for the services of medical women; that the male surgical patient is not the only one to be considered; that there are female wards where the services of a medical woman would be particularly desirable; and that there is ample scope for medical and surgical work for a resident woman apart from the male surgical patients. They say also that the additional accommodation could be prowided at a small cost, and suggest that the advice of a medical woman as to this matter "might be sought with advantage." It may here be pointed out that the claimants for women's rights allowed the planning and building of the infirmary to go on, so far as is known, without pressing the point that there should be provision for women medical residents, which was a tactical error on their part, as never in the history of the institution had the question of women medical residents been brought before the board, or even thought of. The committee for the purpose of securing the admission of qualified medical women to resident posts in the infirmary consists at present of representative members of numerous associations-viz., the Manchester Association of the Federation of University Women, the Manchester Association of Registered Medical Women, the National Union of Women Workers, the Women's Local Government Association, the Women's Trades Union Council, the Women's Co-operative Guild, and a number of "influential men and women." Whether the pressure thus brought to bear upon the infirmary board will be effectual or not remains to be seen. Women can fairly say that when they pay the same fees and are allowed to go up to the same examining boards after going through the same training as men, and when they obtain the same legal qualifications, they should be allowed the same opportunities for practical work in the hospitals. But the world is not governed by logic, for which many seem to be thankful, and there may be reasons why such appointments as are desired would lead to difficulties in working and to less efficient treatment.

Dec. 21st.

UNIVERSITY OF SHEFFIELD.—The Council at its last meeting made the following appointment: Mr. Graham S. Simpson, F.R.C.S., to the Lectureship in Operative Surgery. At the same meeting the Pro-Chancellor (Mr. George Franklin) and the Vice-Chancellor (Sir Charles Eliot) were appointed representatives of the University on the executive committee of the Modern University Congress.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Royal College of Surgeons of Edinburgh.

THE premises of the Royal College of Surgeons of Edinburgh have been in the hands of builders and carpenters for many months past, but have emerged from their hands in a condition which has given satisfaction to all concerned. The old hall in which the Fellows met was quite unbecoming the dignity of such a venerable College, but the new hall, which has been built above it, is in every respect suitable. On the ground floor there is now a long suite of rooms opening off each other and used as libraries, readingrooms, council-room, and writing-rooms. Entrance to the hall above is by the staircase which used to lead to the museum. The museum has been extended lead to the museum. southwards and eastwards by taking in buildings which adjoined the College. A suite of small rooms is fitted up as a laboratory, under the management of the curator of the museum, and furnished with microphotographic apparatus and other necessaries. The entire premises have been redecorated. All the additions and alterations were completed in time for the annual dinner of the College, which was held on Dec. 14th, when the chair was occupied by the College President, Mr. J. M. Cotterill, and amongst the guests were Lord Rosebery and Lord Balfour of Burleigh. Rosebery proposed the toast of "The College" in the felicitous and graceful way which is expected of him on such occasions. He spoke of his forebear, Gilbert Primrose, having been the first recorded Fellow of the College of Surgeons of Edinburgh, and he showed the mortar which had been used by him and bore engraved upon it "Gilbert Primrose, chirurgeon, 1569." He then referred to the state of Scotland at the time when the College got its first charter; and he traced the relations of the surgeons with the barbers. He spoke of the requisites of surgery, and in proposing the toast of the College he associated with it the name of Joseph Lister as well as that of the President. The President replied to the toast, and intimated that Lord Rosebery had been made an Honorary Fellow of the College. On Wednesday evening the President and Fellows of the College gave a reception in their new and renovated premises, which was attended by a large and influential gathering of citizens, when it was felt unanimously that the officials of the College could be warmly congratulated on the skill with which the changes effected had been conceived and worked out.

Compensation for Iuberculosis.

At the annual conference of the Scottish Chamber of Agriculture and Affiliated Societies heldin Glasgow recently, the members were of opinion that where animals apparently sound are exposed for sale in good faith and are, after slaughter, condemned on account of tuberculosis, compensation should be paid therefor out of Imperial funds, and also that the compensation payable under the Tuberculosis Order which comes into force on April 1st next should be a charge, not on local rates, but on the national Exchequer.

Additions to Dundee Royal Infirmary

At the quarterly meeting of the governors of the Dundee Royal Infirmary held on Dec. 13th the chairman asked the governors to sanction several schemes involving expenditure, chief of these being the erection of a new out-patient department. For the sum of £3800 a building could be had, he said, equal to the wants of the infirmary for many years to come. Mr. J. K. Caird, to whom they already owed the Maternity Hospital and the Cancer Hospital, not to mention minor gifts, had offered the sum of £2400 towards the scheme. Accordingly the board asked the governors to sanction the expenditure, of which, owing to Mr. Caird's generous gift, only £1400 would fall on the infirmary funds. It was unanimously decided that the erection of the new out-patient department should be proceeded with.

Sidlaw Sanatorium to be Closed.

The executive committee of the directors of the Sidlaw Sanatorium appointed to consider the financial position of the institution met on Dec. 16th. It was found that while an additional £500 per annum would be sufficient to meet the present deficit, a very much larger sum would be required to place the institution on a really satisfactory basis. They were of opinion that it would be impossible to raise such an

adequate sum by private subscription. The committee accordingly came to the unanimous decision that it would be unwise to attempt to continue the work of the sanatorium under existing conditions and it was agreed to close the institution on Jan. 31st.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Treatment of Maluria.

In the treatment of malaria M. Lemanski strongly recommends intramuscular injections of quinine in preference to administration by the mouth. In speaking on this question at a recent meeting of the Therapeutical Society he pointed out the advantages of the intramuscular method, specifying the rapidity of action, the certainty of absorption, and the absence of unpleasant after-effects or of troubles due to the irritating action of quinine on the stomach. There was also a notable reduction in the amount of quinine required. because the intramuscular administration of a total quantity of 8 or 10 grammes would put an immediate stop to even the longest and most violent attacks, attacks which would not always completely yield to daily doses of 2 or 3 grammes continued even for a fortnight. In some of the various forms of malaria it will often be necessary along with the quinine to give subcutaneous injections of arrhenal and extract of cinchona. In certain cases of malarial hepatic disease, or enlargement of the spleen, or cachexia, much advantage may be derived from hydrotherapy or a course of Vichy treatment. M. Lemanski also said that opotherapic treatment deserved special mention, for daily doses of 60 or 100 grammes of fresh raw spleen were very beneficial to patients suffering from extreme enlargement of the spleen associated with chronic malaria.

Hare Gases in Thermal Springs.

At a meeting of the Academy of Sciences held on Dec. 13th M. Moureu and M. Lepape stated that in the course of their researches on thermal springs they had found that krypton and xenon existed in 26 French springs, including those of Aix-les-Bains, Plombières, Luxeuil, Maizières, Bourbon-Lancy, Bussang, Grisy, Saint-Honoré, La Bourboule, Néris, Bagnères-de-Bigorre, Bagnères de Luchon, Dax, Raux-Bonnes, Cauterets, Salins-Moutiers, La Chaldette, and Uriage.

Dec. 20th.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

Operative Pneumothorax in Phthisis.

Dr. Lucius Spengler of Davos has published a series of 40 cases of operative intervention in phthisis for the production of pneumothorax. The operation was first proposed in 1843 by James Carson and taken up again in 1888 by Fortanini, Spaeth, and Murphy independently of each other. Dr. Spengler recommends the operation solely in severe one-sided affections and according to the method of Murphy and Brauer. He reports 25 satisfactory, 6 fairly good results, 6 indifferent ones, and 3 deaths. In 2 of the latter the disease progressed rapidly after the operation. In the third case an air embolism into the brain took place which resulted in death in three days. A detailed treatise on this subject will shortly be published.

Prevention of Acute Ophthalmia.

Dr. Auguste Dufour treated this important subject in a paper read at a recent meeting of the Medical Society of the Canton of Vaud. Acute ophthalmia attacks 400 children annually in Switzerland, 64 of whom suffer definite loss of vision. Of late years the number is on the increase owing to the negligence of midwives and parents. Dr. Dufour recommends steps to be taken by the Swiss Federal authorities to make general preventive measures such as exist in the cantons of Zürich, Bern, and Fribourg. The following resolutions were unanimously passed:—

1. The midwives are to be reminded of their stringent duty to call in medical advice in case of purulent secretion of the genital tract of the mother and of the eyes of the infant.

 Instructions are to be distributed to all the midwives in Switzerland. Similar printed instructions are to be given gratuitously to the parents by the registrar of births.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Acquittal of a Dental Surgeon Charged with Culpable Negligence.

In a case recently tried before the High Court of Justice the decision of the court, delivered on Nov. 17th, was to the effect that a surgeon is not legally responsible for injurious consequences arising out of an operation which has been conducted in accordance with accepted operative methods. The circumstances were as follows. A business man consulted Dr. Maurice Ronay, a dental surgeon, on account of a broken molar tooth, which was hurting his tongue. Dr. Ronay accordingly began to file off the point of the tooth in question, but during the operation the file slipped off the tooth, not only cutting across the sublingual artery, but also making a wound which measured 5.5 centimetres in length and 1.5 centimetres in breadth. The injury was so severe that the patient had to be conveyed to a sanatorium, where Professor Hültl made an incision measuring 18 centimetres in length on the face, and through this he ligatured the torn vessel. The patient stayed four weeks in the sanatorium and afterwards had to go to a climatic health resort on account of an attack of pleurisy and pneu-monia owing to blood from the sublingual artery finding its way into the trachea. The Attorney-General said that the dental surgeon ought to have used either Pappenheim's or Herbst's tongue protector, and that in failing to do so he was guilty of culpable negligence. Dr. Ronay, in defending himself, said that the accident was the consequence of the patient not following his instruction to keep his tongue on the other side. He further stated that it was not customary in such operations to use either Pappenheim's or Herbst's tongue protector, and to the best of his belief these instruments were not employed, even in the dental clinic of the University of Budapest. The judge thereupon sent for the director of the dental clinic, who corroborated what had been said by Dr. Ronay, and the latter was accordingly acquitted on the charge of culpable negligence. In commenting on the case the judge remarked that a person who submits to an operation must reckon with the possibility that untoward consequences may follow it.

The Antivivisection Movement in Hungary.

In Budapest the opponents of physiological research are endeavouring to revive the old argument that vivisection is useless for the advancement of medical science, and may even be the cause of disastrous errors. A society has been formed for the propagation of these views, the members including several persons well known in society and in the fashionable world. It has not yet, however, made much progress, and at the first meeting held recently in the town hall the attendance was limited.

The Opening of the New Internal Clinic No. 11.

The recent opening of the new Internal Clinic No. II. is an important addition to the medical institutions of Budapest. The buildings occupy an area of 5000 square metres, with a frontage of 80 metres in length; they are four storeys in height and contain 168 beds. The lecture-hall is spacious, airy, and fitted up with every requisite for modern methods of teaching. Apparatus for showing projection pictures, an X ray laboratory, and chemical and bacteriological laboratories are provided. The wards for the reception of patients are admirably designed and fitted up; their sanitary arrangements leave nothing to be desired, and their excellence in all respects is unanimously recognised by the foreign visitors. The nursing of the patients is done by Red Cross sisters.

Dec. 18th.

THE SURGICAL AID SOCIETY.—At the annual meeting of this society, held at the Mansion House under the presidency of the Lord Mayor, it was stated that the year's income amounted to £30,499, against an expenditure of £21,683, which was employed in the supply of 39,204 appliances to 25,424 patients.

NOTES FROM INDIA. (FROM OUR OWN CORRESPONDENTS.)

House-to-House Vaccination.

In a report on vaccination in the Punjab during the past year, Lieutenant-Colonel C. J. Bamber, I.M.S., the Sanitary Commissioner of that province, states that while in most districts the people as a whole have no objection to primary vaccination there is a strong prejudice against the operation of revaccination, partly because it is considered unnecessary and partly because in the case of boys it may interfere in a slight degree with their work. Another factor making against the operation is said to be the lack of interest displayed by municipal members, ziladars, lambardars, and other civil subordinate officials. In the districts of Kangra, Ferozspore, Gujrat, Shahpur, and Muzaffargarh, the decrease in vaccination statistics is directly ascribed to want of energy on the part of those who might be expected to set a good example. Lieutenant-Colonel Bamber, in the course of his report, throws out a suggestion which meets with the approval of the Lieutenant-Governor to the effect that house-to-house vaccination might be introduced experimentally in a few places. "This," he says, "has proved a great success in England in popularising vaccination and is very likely to prove equally successful in this country. This would be also a good method for the distribution of quinine. This measure will meet with opposition from some of the vaccination staff, but the people will undoubtedly welcome a measure that will save them from the exertion and annoyance of taking their children to a distance.

The Distribution of Quinine.

A recent United Provinces gazette contains a resolution on the sale and distribution of quinine as a prophylactic against malarial fever. The Lieutenant-Governor accepts the principle that quinine should not be distributed at public expense (save in charitable dispensaries) unless this measure is necessary to combat a severe epidemic of malaria. From past experience it is calculated that in case of an epidemic the amount that can be distributed among 1,000,000 people is from 1500 to 2000 pounds. As regards the distributing agency, his honour desires the hearty cooperation · of every official. All touring officers should receive a supply for distribution, but for systematic distribution during a severe epidemic non-official agency must neces-sarily be utilised, and in this matter the district boards are primarily responsible. Instructions are given for the procedure to be adopted in arranging for this systematic distribution of quinine. It is considered that except in the case of a severe epidemic the best method of making quinine readily acceptable is by the ex-tension of the pice packet system. The Lieutenant-Governor approves the Commissioner's proposal to increase the amount of quinine sold for a pice from 7 to 9 grains. Additions to agencies for the sale of these packets are under consideration, and arrangements have been made for the experimental issue of the drug in tablet form, three tablets of 3 grains each being contained in a packet. It is quite possible that the larger the sales the greater will be the loss to Government, as it is not yet certain that 9 grains can be sold profitably for a pice $(\frac{1}{4}d.)$. But, whatever the loss, Government is willing, indeed anxious, to incur it in the effort to encourage the use of the prophylactic.

Health of Eastern Bengal and Assam.

Unlike Bengal and many other parts of India, the most prevalent disease in Assam and in parts of Eastern Bengal is due to intestinal parasites. It is under this head that the Inspector-General of Hospitals places the largest number of admissions into dispensaries, which totalled 562,590, or 17.2 per cent. of the total number of patients treated in the dispensaries of the new province during 1908. Malarial fevers and diseases of the skin come next with 547,122, or 16.7 per cent., and 526,528, or 16 1 per cent. respectively. We are not told what the species of the parasites were that attacked such a large number of persons in the new province, nor the nature of the skin diseases, which come third in order of frequency of admissions into the dispensaries. Malarial fever, as might be expected, was responsible for the has been recognised as privat-docent of Neurology.

usual number of attacks one is accustomed to associate with the major portion of the new province; but it is curious to find that, of the total number of malarial fever cases, only 48 were diagnosed as kala-azar, against 61 in the preceding year. This would tend to show that this dread disease is not so prevalent as might have been thought, as it is intimately associated with Assam. There is no reference to "blackwater fever" under this head, but perhaps it is classed under some other head. There was a marked decrease in the number of cholera and diarrhoea patients admitted. The civil surgeon of the Naga Hills reports that goitre is extraordinarily common throughout the district. There is a curious belief prevalent among the natives of Assam that goitre is directly due to the eating of a species of yam, called locally "sootnie." It is not apparent that this general belief has been investigated by medical officers. There is occasionally a substratum of truth in such local beliefs, so that this idea might well be confirmed or exploded by competent investigation.

Plague.

The mortality from plague in India considerably decreased during the week ending Nov. 13th, the total number of cases being 5002, resulting in 3901 deaths. In Bombay there were 647 deaths; in Madras, 91; in Bengal, 202; in the United Provinces, 1122; in the Punjab, 400; in Burma, 22; and in the Central Provinces, 677.

Nov. 25th.

Medical Rews.

VICTORIA UNIVERSITY OF MANCHESTER.—At examinations held recently the following candidates were successful in the subjects indicated :-

THIRD M.B. EXAMINATION.

THIRD M.B. EXAMINATION.

General Pathology and Morbid Anatomy.—K. D. Bean, C. E. Butterworth, Norman Duggan, Jane C. Miller, Manfred Moritz, Lovel Moss, W. Howarth Parkinson, John Rothwell, William Stirling, J. S. B. Stopford, *G. K. Thompson, and William Warburton.

Pharmacology, Therapeutics, and Hygiene.—O. R. Allison, C. B. Davies, E. R. Eatock, W. II. Kauntze, T. W. Martin, Newton Matthews, Lovel Moss. H. G. Peake, S. B. Radley, G. E. Sawdon, C. M. Stallard, and J. P. Stallard.

Hugiene.—C. E. Butterworth

Hygiene.-C. E. Butterworth. SECOND M.B. AND CH.B.

B. B. Berry, † A. G. Bryce, L. T. Challenor, Geoffrey Fildes, C. L. Graham, George Jackson, T. P. Kilner, J. A. Lees, P. H. Midgley, L. W. Sparrow, C. F. White, and A. G. Wilkinson.

Anatomy.—C. T. G. Bird, G. C. Dixon, and W. H. Wood.

DIPLOMA IN DENTISTRY (THIRD EXAMINATION). Vernon Ditcham, S. I. Fillingham, F. B. Preston, Norman Vickers, and R. S. Ward.

Anatomy, Dental Anatomy, and Histology.—Wilfrid Jackson.

* Distinction in Pathology. † Distinction in Physiology.

University of Liverpool.—At the examination for the Diploma in Tropical Medicine held recently, the following candidates were successful :-

B. R. Armstrong, M.B., Ch.B.; G. Beatty, M.B., C.M.; C. L. Chevallier M.R.C.S., L.R.C.P.; W. Fleming, M.B., Ch.B.; H. M. Hanchell, M.R.C.S., L.R.C.P.; S. A. Henry, M.A., M.B., B.C.; F. A. Inness, M.A., M.B., Ch.B.; A. F. Jackson, B.A., M.B., B.C.; S. M. Kaka, M.R.C.S., L.R.C.P.; A. A. D. McCabe-Dallas, L.M., Lic. Med.; K. B. Shroff, L.M. & S.; Violet A. Turkhud, M.B., B.S.; and F. Yen, M.D.

Foreign University Intelligence .-Borne: Professor A. Siegrist, Director of the University Ophthalmic Clinic, has declined an invitation to Strasburg as successor to Professor Schirmer.—Berlin: Dr. Ernst Weber has been granted the title of Professor.—Bonn: Dr. Prym has been recognised as privat-docent of Pathological Anatomy and General Pathology.— Göttingen: Dr. Göppert has been appointed Extraordinary Professor of Children's Diseases.— Marseilies: Dr. Treille has been appointed Clinical Professor of Tropical Diseases, a newly created chair.—New Orleans (Tulane University): Dr. Henry W. Stiles has been appointed Adjunct Professor of Anatomy.—Padua: Dr. Annibale Preto has been recognised as privat-doesn't of Operative Medicine. -Philadelphia (Medico-Chirurgical College): Dr. J. Hamilton Small has been appointed Adjunct Professor of Bacteriology. Strasburg: Dr. Georg Ledderhose, Extraordinary Professor of Surgery, has been entrusted with the courses of lectures on Forensic and Social Medicine. - Turin: Dr. G. Roasenda

University College (University of London). —On Dec. 17th a new department of botany was opened at University College by Mr. D. H. Scott, Ph.D., Vice-Chancellor of the University. The suite of 15 rooms has been made available by the migration of the old physiological department to the new institute of physiology.

Apothecaries' Hall of Ireland.—The preliminary examination for candidates seeking this licence will take place on Monday, Jan. 3rd, 1910. The quarterly examinations will be held on the following dates: First professional, Monday, Jan. 3rd, 1910; second professional, Thursday, Jan. 6th; third professional, Monday, Jan. 10th; and final professional, Wednesday, Jan. 12th.

EARTHQUAKE IN ARMENIA.—Our Constantinople correspondent writes that according to a telegram from Bitlis a violent earthquake has completely destroyed the locality of Ernit. One village disappeared from the face of the earth and four others suffered greatly. 70 houses have been levelled with the ground and 40 persons perished under

DEATHS OF EMINENT FOREIGN MEDICAL MEN. The deaths of the following eminent foreign medical men are announced:—Dr. A. O. Lindfors, professor of gynsocology in the University of Upsala.—Dr. Heinrich Adler, editor of the Wiener Medizinische Wochenschrift, aged 61 years.—Dr. Niels Peter Schierbeck, docent of hygiene in the University of Copenhagen.—Dr. Antonio Ripamonti, prival-decent of neurology in the Florence Medical School and councillor in the Commune of Milan.

Drainage of St. Petersburg.—On the subject of the drainage of the Russian capital a correspondent of the Novoe Vremya, after pointing out the exceptional death-rate of the town, 28 per 1000, with that of other capitals of the world—e.g., Moscow, 25; Rome, 18; Vienna, 17; Paris, 17; Berlin, 15; and London, 15—and enumerating the practically endemic position of some of the infectious diseases that rage there and the threatened permanence of cholera, which has held its position since autumn of last year (1908), proceeds to describe the drainage system prevailing, to which, making allowance for the poverty of the working classes, he ascribes most of the terrible mortality recorded. The chief cause, he says, is the exceedingly dirty condition of the ground of the town and its rivers and canals. The sewage, both and liquid, is carried in a most primitive way through badly constructed wooden tubes to the rivers and canals that run through the town. Much of the filth leaks through the tubes into the soil and, further, the system is so badly levelled that the liquid impurities gather by gravitation in places and form sickening pools. On the rare occasions when these tubes are cleaned out—usually by shovels—the filth is flung on to the open ground to infect the surrounding atmosphere for a greater or less time. Much of the sewage is removed in imperfectly equipped carts, and in the sparsely inhabited parts of the town the men simply throw it out on the roads or into the local canals. Some collections, particularly the Glucho-oserskaya, flow in a stream into the Volchovka river and thence into the Obvodnoma canal, thus flowing back into the town. This collection has not been disinfected for the last 20 years. The effect of this neglect on the soil of St. P. tersburg has been such that some of the ground taken from the courtyard of the Nikolaieff Military Hospital, on chemical analysis, yielded seven times as much nitrogen as the soil taken from cemetery graves. The ground water near the Kriukoff canal has a strong smell of sulphuretted hydrogen, and has been known frequently to cause men who have been engaged digging foundations to swoon. The rivers and canals are simply open sewers. To what extent the town water is infected may be judged from the fact that the Fontanka river, even in the coldest weather, does not freeze in the "lower strata." The only advantage of the present system, says the writer of the article, is its cheapness, and that is why the question of the drainage of the capital, though under debate since 1864, has not been decided. He believes that the limits of nature are being approached, and that without radical measures the city must undergo a vital and economic disaster.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANGET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication

CANNEY, J. R. CAMPBELL, M.B., B.C., has been appointed Resident Medical Officer at University College Hospital.

CLIFFORD, HAROLD, M.B. LOND, F.R.C.S. Edin., has been appointed Registrar to the St. Mary's Hospitals, Manchester.

COLLINS, G. F., L.R.C.P. Irel., M.R.C.S., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Sutton Bridge District of the county of Lincoln.

FITZWILLIAMS, DUNCAN C. L., M.D., Ch.M., F.R.C.S. Edin., F.R.C.S. Eng., has been appointed Surgeon-in-Charge of Out-patients at St. Mary's Hospital.

GORDON, S. G., L.R.C.S., L.R.C.P. Irel., L.M., has been appointed Assistant Resident Surgeon at the General Dispensary, Nottingham.

HOBES, EDWARD COOMER, M.R.C.S., L.R.C.P. Lond., has been appointed House Physician to the West London Hospital, Hammersmith.

appointed House Physician to the West London Hospital, Hammersmith.

McCully, D., M.R.C.S., L.R.C.P., has been appointed House Physician at University College Hospital.

MacManon, A. P., M.B., B.S.R.U.I., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Clondalkin District of the county of Dublin.

Rayner, H. H., M.B., B.Ch. Vict., F.R.C.S. Eng., has been appointed Honorary Surgeon for Children at the Northern Hospital, Manchester.

Shattock, C. E., M.R.C.S., L.R.C.P., has been appointed Obstetric Assistant to University College Hospital.

SHAW, W. F.. M.D. Vict., has been appointed Pathologist to the St. Mary's Hospitals, Manchester.

SIMPSON, GRAHAM, F.R.C.S. Eng., has been appointed to the Lectureship in Operative Surgery in the University of Sheffield.

WHITE, CLIFFORD, M.D., B.S. Lond., M.R.C.P. Lond., F.R.C.S. Eng., has been appointed Obstetric Registrar to University College Heapital Hospital.

Pacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BATLEY, BOROUGH OF.—Medical Officer of Health and Medical Inspector of School Children. Salary £300 per annum.

BELGRAVE HOSPITAL FOR CHILDREN, Clapham-road, S.W.—House Surgeon for six months. Salary at rate of £20 per annum, with board and residence.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—Senior House Surgeon. Salary £25 per annum.

BOURNEMOUTH, ROYAL BOSCOMBE AND WEST HANTS HOSPITAL.—House Surgeon. Salary £30 per annum, with board, lodging, and washing.

washing.

BRISTOL ROYAL INFIRMARY.—Honorary Dental Amesthetist.

BUXTON, WYE HOUSE ASYLUM,—Assistant Medical Officer.

£120 per annum, all found.

CANCER HOSPITAL, Fulham-road, S.W.—Assistant Amesthetist.

Salary

95 witness per annum.

CANCER HOSPITAL, Full maintrious, D. W. - Instant.

25 guineas per annum.

CHARTHAM, KENT COUNTY ASYLUM.—Third Assistant Medical Officer.
Salary £145 per annum, with board, quarters, attendance, and washing.

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Clinical

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Clinical Assistant.

BAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—House Physician. Salary at rate of £75 per annum, with board and residence.

FARRINGDON GENERAL DISPENSARY AND LYING-IN CHARITY, Bartlett's Buildings, Holborn-circus, E.C.—Honorary Physician.

GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—Assistant House Surgeon. Salary £50 per annum, with board, residence, and laundry.

laundry.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—
House Surgeon, unmarried, for six months. Salary £30, with
board and residence.

board and residence.

HULL ROYAL INFIRMARY.—Casualty House Surgeon. Salary at rate of £60 per annum, with board and lodging.

INDIAN MEDICAL SERVICE, India Office, London.—Thirteen Commissions in His Majesty's Indian Medical Service.

LIVERPOOL SCHOOL OF TROPICAL MEDICINE.—Research Students on Malaria, Parasitology, Pathological Chemistry. Salaries £150 to £250 per annum. Also Research Assistant at the Runcorn Laboratories. Salary £120.

LONDON THROAT HOSPITAL, 204, Great Portland-street, W.—House Surgeon. Salary £50 per annum.

MANCHESTER CHILDREN'S HOSPITAL, Gartside-street.—Assistant Medical Officer. Salary £100 per annum.

MANCHESTER ROYAL INFIRMARY.—Medical Registrar. Salary £70 per annum.

annum.

MEDICAL MISSION HOSPITAL, Balaam-street, Plaistow, E.

MEDICAL MISSION HOSPITAL, Balaam-street, Plaistow, E.—Assistant Doctor (female) for six months. Board, residence, and laundry.

MONTREAL, ROYAL VICTORIA HOSPITAL.—Pathologist.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Hampstead and Northwood, Middlesex.—Physician.

NAVAL FORCES IN THE UNITED KINGDOM.—Two Dental Surgeons. Salary £1 per diem, and travelling expenses.

ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN,—Honorary Physician to Out-patients.

SHEFFIELD ROYAL HOSPITAL.—Assistant House Physician. Salary £50 per annum, with board, lodging, and washing.

SOUTHAMPTON, FREE EYE HOSPITAL.—House Surgeon. Salary £100 per annum, with board and residence.

YARMOUTH COUNTY BOROUGH.—Medical Officer of Health. Salary £400 per annum.

Births, Marriages, and Meaths.

BIRTHS.

CORNWALL.—On Nov. 28th, at Westcliffe, Coonoor, the wife of Major J. W. Cornwall, I.M.S., of a son.

HOTCHKIS.—On Dec. 20th, at Mid Dykebar, Paisley, the wife of Robert Dunmore Hotchkis, M.D., of a son.

TOWNSEND.—On Dec. 12th, at Naval-terrace, Sheerness, the wife of Surgeon Evelyn R. Townsend, R.N., of a son.

MARRIAGE.

St. John-Twigg.—On Dec. 18th, at St. Peter's, Cranley-gardens, Winston St. Andrew St. John, M.R.C.S., L.R.C.P., to Violet Julia Louisa, second daughter of Henderson James Twigg.

DEATHS.

BRUMWELL.—On Dec. 15th, at Barden, Shanklin, Isle of Wight, Joseph Cownley Brumwell, M.D., J.P., late of Burnley, aged 86. Turner.—On Dec. 17th, at 11, Heathfield-gardens, Chiswick, Ann Louiss, widow of the late William Hall Turner, M.R.C.S., L.S.A. (Guy's), in her 91st year.

N.B.— A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Rotes, Short Comments, and Answers to Correspondents.

THE CAMPAIGN OF THE NATIONAL FOOD REFORM ASSOCIATION.

THE committee of the National Food Reform Association has issued a circular calling attention to the widespread physical degeneracy of the people of Great Britain as revealed in the evidence before the recent Inter-Departmental Committee on Physical Deterioration; the very general ignorance of household management, and particularly respecting the choice and preparation of food; and the close connexion between improper, inadequate, and unscientific feeding and the drinking habits of the people, to which the same committee refers. The association asks for support in its efforts to bring this serious state of things to the notice of Parliament by (1) urging the Government to publish, in a popular and easily accessible form, full information as to the nutritive value of foodstuffs, as is done in the official bulletin issued by the Office of Experiment Stations in connexion with the U.S.A. Department of Agriculture; (2) supporting a proposal for a Government inquiry into the feeding of the army and navy, both at home and abroad, the inmates of prisons, workhouses and other institutions, and of underfed scholars, with the object of procuring a maximum efficiency with a minimum expenditure of public money; (3) endeavouring to secure the more systematic and scientific teaching of cookery, hygiene, and domestic economy in schools and continuation classes, these subjects being, as far as possible, made compulsory for the older girls, as recommended by the Inter-Departmental Committee; (4) demanding the provision, in every dwelling let for the occupation of a family, of a grate suitable for cooking; (5) advocating the passing, at the earliest possible date, of a Milk Bill on the lines of that introduced by the President of the Local Government Board; (6) asking that it be made compulsory for each patent medicine to bear a label setting out in detail the ingredients of the same, their proportions, and the diseases they profess to cure; and (7) endeavouring to ensure that the legislation on the subject of inebriates, promised by the Home Secretary for next session, shall take into account the evidence as to the efficacy of the dietetic treatment of inebriety furnished by the Salvation Army Homes for Women Inebriates.

THE MANUFACTURE OF NITROBENZOLS AND ANILINE COMPOUNDS.

To the Editor of THE LANCET.

SIR,-With reference to the query on p. 1870 two references are-Effects of Dinitrobenzene and other Nitro-substitution Products, by R. Prosser White, M.D. (Oliver's "Dangerous Trades," p. 475); Observations on the Condition of the Blood in Men Engaged in Anilin Dyeing and Manufacture of Nitrobenzine and its Compounds, by W. Malden, M.D. (Journal of Hygiene, vol. vii., October, 1907).

I am, Sir, yours faithfully, Home Office, London, S.W., Dec. 21st, 1909.

To the Editor of THE LANCET.

SIB,-Your correspondent "S. F. C." will find information upon the first of these two substances in an article entitled "The Poisonous Properties of Naphthalene and the Aromatic Compounds," THE LANCET, August 31st, 1901; also vide "Dangerous Trades," by Thomas Oliver, Chapter XXXII. Experimental inquiry into the local and constitutional effects of aniline and its salt is at present much needed.

Wigan, Dec. 18th, 1909.

I am, Sir, yours faithfully, R. PROSSER WHITE.

INDOOR BED TENTS.

In the Scientific American of Dec. 4th a lady contributor describes two methods by which persons sleeping in an ordinary bedroom may breathe the external atmosphere and not the air of the apartment. The method which she prefers is that of the fresh-air tent fastened inside the window. The side of the bed near the top is placed close to the open window. The tent, which is made of heavy canvas or awning cloth, comes down from the inside of the window across the bed over the pillow, so that the sleeper when his head is under the tent can breathe the fresh air from the window, while the rest of the body is in the bed covered by the bedclothes and in a warm room. A little celluloid window in the side of the tent next to the room allows the user to see into the room and to converse with whoever may be there, and two persons can sleep in the same bed with only one of them being under the tent. If wished, the sleeper may wear a flannel hood the cape of which covers the shoulders and protects them if the bedclothes should slip off.

A GARBAGE-MONGER PUNISHED.

An elderly man, described as illiterate, and to whom the magistrate's clerk had some difficulty in explaining the nature of the charge which he had to answer, was recently summoned at the Guildhall which he had to answer, was recently summined to the children police court as the owner of the carcasses of four pigs seized and condemned at the Central Meat Market. The defendant, Henry Butler, was stated to be a pig and poultry dealer at Alphamstone in Suffolk, and out of 12 carcasses of pigs sent by him on the same day to London to serve as food for its imbabitants, four were so unmistakeably tuberculous that the alderman who heard

the charge, and who happened also to be the magistrate who condemned them informed the defendant, that without who condemned them informed the defendant, that without claiming to be an exert, he had found their condition perfectly apparent at once o his "unskilled eyes." It was suggested with some reason by the Assistant City Solicitor, who prosecuted, that if the defendant we so ignorant that he did not appreciate the nature of the meat he as consigning to the London market, there was a stage of ignorant or carelessness at which such a mental condition became criming. On heling seattened to make fine of 240 condition became crimin. On being sentenced to pay a fine of £40 with £4 costs or to go t prison for a month, the defendant observed his only assets were a wold horses, and philosophically declared his intention to "take ti month."

Medical Diar for the ensuing deek.

EDITORAL NOTICES.

IT is most important the communications relating to the Editorial business of TH LANCET should be addressed seachesizely "To THE EDIR," and not in any case to any gentleman who may be suposed to be connected with the Editorial staff. It is urgent necessary that attention should be given to this notice.

It is especially requested the carly intelligence of local events having a medical interes or which it is desirable to bring under the notice of therefession, may be sent direct to this office.

Loctures, original articles, nd reports should be written on one side of the paper lly, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUITED THAT THE NAME OF THE AUTHOR, AND IF POSE LE OF THE ARTICLE, SHOULD BE WRITTEN ON THE LOCKS TO FACILITATE IDENTI-PICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or nows paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page for the current half-year is published in this issue, which completes the second volume of the year 1909.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1909 will be ready shortly. Bound in cloth, gilt lettered, price 18s., carriage extra.

Cases for binding the half year's numbers are now ready. Cloth, gilt lettered, price 2s., by post 2s. 3d.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion what-ever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

Until the end of the present year copies sent by post will be charged at the rate of $7 \pm d$. inland and 8d. abroad.

Commencing with the issue of Jan. 1st, 1910, the rates of subscriptions, post free from THE LANCET Offices, will be :-

FOR THE UNITED KINEDOM.
One Year £1 1 0
Six Months 0 12 6
Three Months 0 6 6
Three Months 0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs. 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed 'London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANGET Offices, 423, Strand,

London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABBOAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA-Messis. WILLIAM WOOD AND Co., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS. (Taken daily at 8.30 a.m. by Steward's Instruments.)
